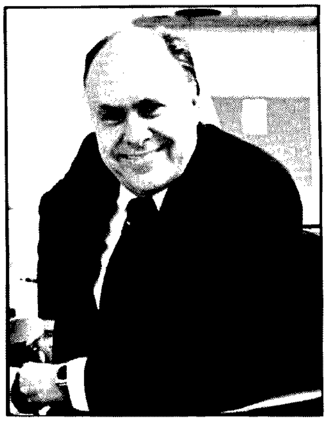
W2NSD/1 NEVER SAY DIE

editorial by Wayne Green



ATLANTA, JUNE 16-17

While June is a very busy month in both the microcomputer and ham businesses, no year would be really complete without a trek to Atlanta for the Atlanta Hamfestival. First, I'll be down to Dallas on June 2-3 and be giving talks at the Dallas hamfest on both computer programming and on the present state of affairs in amateur radio.

My next stop will be New York and the National Computer Convention (IEEE), where I will talk about computer program development and sales. That's June 5-7, if you're in the vicinity.

Atlanta's hamfest has been growing year by year and is starting to give Dayton some worries. There are an awful lot of hams in the southeastern part of the country, and just about every one of them packs up his family and heads for Atlanta come June. Thousands come in from every southern state. It's a madhouse . . . and it's a ball.

Chaz Cone, the chap who has been pulling this event off (not without a lot of able help), has come up with some incredible prizes . . . last year they gave away a car with a complete ham rig installed. There are so many prizes that it is difficult to escape getting something which is worth more than the registration fee.

I'll be there and be giving a couple of talks . . . one on computing, with the emphasis on amateur radio . . . and not a little information on how to get into computing and take advantage of the incredible growth which this field still has ahead of it. Never before have there been so many opportunities to make a fortune . . . if you're willing to work for it. The money is there, waiting for anyone who really wants it.

The other talk will be ham-oriented and will try to put the past, present, and future into perspective. Does Wayne really hate the ARRL, or is this a figment of the imagination foisted on a gullible public by Newington?

What is Wayne really like? Is he the prophet of doom and gloom or is he a pragmatist, calling the shots the way they are? Is Wayne really as rich as some people from Connecticut say he is? And how in the devil did *73 Magazine* get to be the largest in the ham field? Bring your questions, and Wayne will answer them.

In addition to exhibits by most of the top ham equipment firms, you'll find dealers fighting tooth and nail for your business. Many are bringing trailer loads of ham gear to try to sell before the summer slump. There will also be some exciting displays of the latest in personal and small business computers. Maybe it's time for you to get more familiar with these little buggers and integrate one into your ham station . . . and home?

THOSE TOLL-FREE NUMBERS

A letter from Ed Leviton AB3B points out that the Federal Trade Commission has rather strong rules to protect mail-order buyers, but when you order over the telephone, you forego this protection. The entire text of the mail-order merchandise rules are lengthy and have some strong teeth. A copy can be obtained from the Government Printing Office, CCH booklet #4803, $1.50.

If you are lazy, like me, and prefer to use the phone, then it's caveat emptor (buyer beware).

ON TOP OF OLD SMOKEY

A recent court case (People v. Case—NY—365NE2d 872, 87ALR3d 77) involved a CBer who reported a radar checkpoint over his radio and was arrested for this. He was convicted in a justice court, and his conviction was upheld in the County Court. It was then reversed by the Court of Appeals. This court held that "under the statute making the obstruction of governmental administration a crime, obstruction must be by means of intimidation, physical force, or interference, or by means of any independently unlawful act and that the defendant's verbal message via his Citizens Band radio did not constitute a physical interference with governmental administration."

Since people seem to worry about that aspect of CB and hamming, I thought you'd like to know and have the reference.

Another lawyer has promised to write and let me know more about a situation which has developed in his area in which hams are virtually exempt from radar-inspired speeding tickets by virtue of the unsettling effects of a two meter rig in the car.

My thanks to Attorney Duncan Kreamer W1GAY for the above reference.

THE ROVING CAMERA

As if things aren't bad enough in New Hampshire in February (unless you happen to be a skier), the Interstate Repeater Society (I detest the

Newhall CA 91321

Having just celebrated my thirty-eighth birthday, and remembering back to my teens and the traumas I went through to obtain my amateur license, I was kind of amazed the other evening when my friend Harvey Ross WB6YNO recounted the story of how his now nine-year-old became General class licensee WD6FLP not long ago. It's an interesting story, and I'd like to share it with you.

I've known Harvey and his wife Bonnie WA6SNB almost from the day we moved to Los Angeles. We first met on the air via the PARC WR6ABB repeater and were later formally introduced by Walt W6EJK. As Harvey tells it, one day close to two years ago he was busy operating 20 CW when his son David asked him to teach him Morse code. After some thought, Harvey not only agreed to do so, but also made a game out of the project. David was fast to catch on, and it was not long before he had mastered the 5 wpm necessary to pass the Novice exam.

To help David with the theory, Harvey enlisted the help of a friend named Bill Ellis. Bill, whose callsign is WA6USB, runs what is possibly the nation's most successful amateur training school: Murphy's Amateur Radio Class, which meets weekly in Culver City, California. At Bill's suggestion, Harvey enrolled David in Murphy's Novice training program; the move was a very successful one. For his eighth birthday, David received quite a present: amateur callsign WD6FLP. Now, many youngsters would be content with attaining a goal such as this and move on to other things. However, in that regard, David is not your average youngster. He had developed a love for amateur radio, and a Novice ticket would just not suffice. He continued working toward his next major goal, a General class license.

In July of 1978, David thought it was time to try. Though he literally breezed through the CW exam, the theory stumped him. He was kind of disappointed—but in no way beaten. Back to the books he went, so that next time the elusive General ticket would be his. His tenacity paid off on December 14, 1978, when he walked out of the FCC office in Long Beach, California, with General class privileges and the ability to sign WD6FLP—interim LB. His first QSO? It happened to be on 450 MHz to inform his very proud father that he had made it!

What does a nine-year-old General do, you ask? The same as any other ham. He operates all bands, belongs to radio clubs, and is probably the youngest person to be found on a remote-base system anywhere. Oh, yes, in his spare time David is hard at work with his younger sister, teaching her code in hopes of making it an all-amateur-radio family.

The case of Scott Lookholder WB6LHB is another matter entirely. We have been following this legal matter since it became public some months ago, and here is the final chapter. On February 6th, Judge Lawrence T. Lydig in Los Angeles Federal District Court passed sentence upon Mr. Lookholder, who had earlier, on January 10th, pleaded guilty to three counts of using foul and abusive language on the air. The sentence broke down as follows: count 1—$500 fine; count 2—$500 fine; count 3—one-year probation. In addition, the court has forbidden Mr. Lookholder to use his amateur privileges for the term of the probation, and, while not making it a mandatory part of probation, the court did suggest that Mr. Lookholder seek psychiatric care. In his closing remarks just prior to the passing of sentence, the court described Mr. Lookholder as "being a disgrace to himself, his family, and the amateur service."

Lookholder's alleged operations as "W6JAM" had raised havoc over a number of Los Angeles area 2 meter repeaters for several months. Particularly hard-hit had been WR6ABN, and it has been thought that many ABN users would be present for the sentencing. Alas, that was not the case. As is usual in amateur circles, apathy dominated the day, with but four area amateurs in attendance. Earlier, when the court was soliciting voluntary written statements from those who had been adversely affected by Mr. Lookholder's operations, only eight area amateurs took the time to write at all. Eight out of close to 20,000! The fact that not even 1% of the total ABN usership (which these days numbers close to 400) took the initiative to express their views to the court when requested is a rather sad commentary on the overall amateur society. Yet, during the "W6JAM Reign Of Terror," hundreds of anti-W6JAM comments could be heard each day. Now, the average on-the-air commentary is to the effect that the court was far too lenient in the case. To those who had their chance to affect the case and were too lazy or apathetic to utilize it, I can only say, "you blew it."

I do not wish to single out the overall ABN usership for admonishment in this matter. Letters from other parts of the nation tell the same story. A jammer is caught, and when it comes to the nitty-gritty of prosecution, everyone suddenly disappears. One or two are left to do the work for many. On-the-air rhetoric against the offender is loud and boisterous, but overall cooperation is nil. Maybe this is the reason for the development of a new kind of interference-tracing and -documentation method, the quiet clandestine operations which simply gather input and develop airtight legal cases. In many areas, it has become obvious that trying to get the assistance of the average "Joe Ham" has become impossible. Sure, he cares, but not enough to get out and T-hunt the offender or even write a letter of complaint. So, in many locations, the small number of people who really are concerned are banding together. Probably you will never know who they are until the time arrives when a major offender is brought to justice. Perhaps not even then. The Lookholder case has proven one thing to many: It has shown that our legal system can and will work if we are prepared to use it. Action taken

David Ross WD6FLP.

TASMA's 1979 leadership: Chairman Bob Thornburg WB6JPI (left) and Vice-Chairman Dave Ferrone WA6KOS.

OMNI HAS IT *ALL*. All the advantages and capabilities, all the new conveniences and new levels of performance you need, whatever your HF operating specialty. All built-in, ready to use.

***ALL* SOLID-STATE.** All the advantages of total solid-state from the pioneer of HF solid-state technology. Reliable, cool, stable — from receiver front-end to transmitter final.

***ALL* HF BANDS.** From 160 through 10 meters (and all the crystals) plus convertible 10 MHz and "AUX" band positions for possible future needs.

***ALL* BROADBAND.** Band changing without tuneup — without danger to the final amp.

***ALL* READOUTS.** Choose OMNI-A for analog dial (1 kHz markings) or OMNI-D for six 0.43" LED digits (100 Hz readability.)

***ALL* VOX AND PTT FACILITIES** built-in; 3 VOX controls plus PTT control at front and rear jacks for external PTT switch.

***ALL* SQUELCH NEEDS** for tuning and monitoring are built-in.

***ALL* FILTERS INCLUDED:** 4-position CW/SSB filter (150 Hz bandwidth with 3 selectable skirt contours) plus 8-pole Crystal filter (2.4 kHz bandwidth, 1.8 shape factor.)

***ALL* MODE SWITCH** puts all filters to work in any mode.

***ALL* BREAK-IN:** Instant or delayed receiver muting to fit any band condition or mobile operation.

***ALL*-VERSATILE OFFSET TUNING;** dual ranges, ±5 kHz range for off-frequency DX or ±0.5 kHz range for fine tuning.

***ALL*-SENSITIVE RECEIVER;** from 2 μV on 160 m to 0.3 μV on 10 m (10 dB S+N/N) for ideal balance between dynamic range and sensitivity.

***ALL* OVERLOADS HANDLED;** dynamic range typically exceeds 90 dB and PIN diode switched 18 dB attenuator also included for extra overload protection.

***ALL* LINEAR/ANTENNA BANDSWITCHING FROM FRONT PANEL;** auxiliary bandswitch terminals on back panel for external relays or circuits are controlled simultaneously by the OMNI bandswitch.

***ALL* INTERFACE JACKS FOR PHONE PATCH;** access to speaker and microphone signals.

***ALL*-LEVEL ADJUSTABLE ALC;** set output from low power to full, retain low distortion at desired drive to power amp.

***ALL* SIDETONE ADJUSTMENTS;** pitch and volume.

***ALL*-POWERFUL, *ALL*-WARRANTED FINAL AMPLIFIER.** 200 watts input to final. Proven design with full warranty for first year and pro-rata warranty for additional 5 years.

***ALL* 100% DUTY CYCLE.** For RTTY, SSTV or sustained hard usage.

***ALL*-MODE POWER:** basic 12 VDC for easy mobile use, external supplies for 117/220 VAC operation.

***ALL* FRONT PANEL MICROPHONE AND PHONE JACKS.** Convenient.

PLUS *ALL* THE OTHER HANDY BUILT-INS: "Timed" 25 kHz crystal calibrator in OMNI-A with automatic 5-10 sec."on" time for easy 2-hand dial skirt adjustment... Zero-Beat switch for placing your signal exactly on CW listening frequencies... SWR bridge switches "S" meter to read SWR each time you transmit for continuous antenna monitoring... Separate receive antenna capability... Dual speakers for greater sound at lower distortion... Plug-in circuit boards for fast, easy field service.

***ALL*-FUNCTIONAL STYLING.** "Clamshell" aluminum case clad in textured black vinyl with complementary nonreflective warm dark metal front panel and extruded aluminum bezel and bail. Convenient controls. Complete shielding. And easier-to-use size: 5¾"h x4¼"w x 14"d.

AND *ALL* THE OPTIONS: Model 645 Keyer, Model 243 Remote VFO, Model 248 Noise Blanker, Model 252MO AC Power Supply.

Model 545 OMNI-A $899 **Model 546 OMNI-D $1069**

Experience the *all*-encompassing HF world of OMNI. See your TEN-TEC dealer or write for *all* the details.

DX PROFILE

This month's DX Profile is on one of the better-known DXers in the world, Dr. San Hutson K5YY/K5QHS, of Little Rock, Arkansas.

San's ham career began in the mid-1950s when he picked up an old S-38 receiver and started monitoring the ham bands. After receiving a few QSL cards, he decided to get in on the action side of the hobby and applied for his Novice exam. San received his Novice license in 1958, along with the call KN5QHS, and four months later he passed the General class exam. In 1977, San upgraded to Extra class and received his present call, K5YY.

San has always been primarily a DXer, but because of college he missed a few years. During that time, he also missed several now-deleted countries that would have brought his DXCC total to nearly 350. As it is, his total still stands at 333, and he needs only BY and VS9K to have them all.

Due to his medical practice, San has moved around quite a bit since receiving his medical degree from the University of Arkansas in 1969. However, all of his operating has taken place inside the state of Arkansas (with the exception of two years spent in Broken Bow OK).

San's first DXpedition was the only authorized DXpedition to Swan Island. In the eight years since, he has become one of the most traveled amateurs in the country, operating from CE0Z, CE3, ZF1, KS4, VP2D, FM0, FG0, FL8, FH8, D6, ST2, ST0, 3B8, and 5H1, along with F0, I0, and G. San was the first to operate from D6 and the first to activate two new DXCC countries on a solo effort when he operated from D6A and FH8 in 1976.

His DXpedition experiences have made San much in demand as a featured speaker at DX gatherings across the country. He has spoken to the Arkansas DX Association many times, the W9DXCC banquet twice, DXpo, SEDXA in Atlanta, and many others.

A past president of the ADXA and presently head of the Executive Committee, San was recently appointed to the ARRL DX Advisory Committee. He feels this DXAC appointment to be the crowning point in his twenty years of hamming, especially in light of the serious aspects of WARC '79 and present DXCC disgruntlement facing the committee.

Still in his mid-30s, San is the Senior Medical Consultant for Social Security in the state of Arkansas. He is married and the father of three children (aged four, ten, and eleven). Other than amateur radio, his hobbies include sporadic coin collecting (mostly pennies from 1850 on) and Corvettes—he has owned 13 Corvettes in the last 11 years. He enjoys hunting and tries to go deer hunting every year. He also enjoys all sports and, true to the medical profession, he is an avid golfer.

Somewhat of an equipment collector, his present station includes two Signal Ones and a home-brew 4-1000 linear, a Drake C-Line and Alpha linear, a Collins KWM2-A and L4B linear, the Kenwood twins with a two meter hookup, and a 75A4 receiver. Antennas include a Telrex beam for 20, a duobander for 10/15, a sloper for 40, a dipole for 80, and a loop and shunt-fed tower on 160. He says that his first real antenna was a five-element Telrex twenty meter beam at 130 feet, but since moving into larger cities, he has had to compromise somewhat.

San Hutson K5YY and his station in Little Rock. San says the station changes constantly, but this is it at the moment.

He hopes some day to have a super station with several operating positions for visiting hams and contests. San likes contest operation on the low bands and has over 60 countries confirmed on 160 meters.

San is planning another DXpedition for later this year and says he will always be planning one of some sort. One of the most interesting aspects of DXpeditions is meeting and getting to know other hams all over the world. On his last trip alone, San met ST2SA, ST2HF, 3B8DA, 3B8DA, 3B8CJ, FH8OM, FH8YL, FH8CJ, D68AD, I0MGM, and many others in Italy, Great Britain, and along the way.

Respected as a DXer around the world, San was the ADXA DXer of the Year in 1973. He also won the Virginia Century Club Award in 1976, the ADXA Achievement Award in 1977, and the Diplome du T.F.A.I. in 1976, and holds certificates for A1 Operator, WAZ, WAC, WAS-160, DXCC Honor Roll—phone and CW—and many more.

San claims that once he works BY and VS9K to have them all, he will just sit back and play with his sports cars. We find that hard to believe. The feeling here is that whenever and wherever there is a new one to be worked, K5YY will be on one end of the pileup or the other.

HEARD ON THE BANDS

With the recent mutual recognition between the U.S. and China, the feeling among many DXers is that BY stations will soon be blossoming everywhere. Although the chances for a true-blue BY-type operation from downtown Peking are better than they have been in many years, those with inside knowledge believe it may still be a bit premature to expect any immediate action, especially by any visiting U.S. operators.

The operation, when it comes, will most likely develop along the lines of the Iraq activity, where some YUs were able to help the locals develop their skills and form a national radio club. Already, several foreigners working inside China have been allowed to bring in their transceivers and install antennas for listening purposes.

On January 17th, ON4QX reported working a station signing BY1AA at 1406Z on 14010. The operator gave his name as Pyng, was very fluent in English, and said to QSL via Box 68 in Peking. Many Europeans and some W/Ks heard the signal, but apparently ON4QX was the only one to get through. Chances are this was Peking Slim, but Bob is watching the China mail nonetheless.

Where-there-is-a-will-there-is-a-way department . . . N5XX tired of trying to work through the large and unruly mob chasing 3Y1VC on Bouvet and decided there must be a better way. He obtained the telephone number of LA5NM in Norway, telephoned long distance, and persuaded LA5NM to ask 3Y1VC to listen for him after their daily 10 meter CW sked. It worked, and Clark was able to add a rare new one to his DXCC total. Clark says the long-distance charges were only $3.75 for 3 minutes, but he didn't say how many 3 minuteses the persuasion took.

The forthcoming trip in the Pacific by Peter Sutter calls for his vessel, *Wild Spirit*, to be at VR3/Christmas around June 15th, VR3/Fanning around June 20th, and KH5/Palmyra around June 24th. Exact times depend largely upon the trade winds and currents.

The reciprocal licensing agreement between Haiti and the U.S. has apparently hit a snag, with no further action being taken. While on the subject of Haiti, we might mention that the HH authorities report no such license exists for HH2SL who has been showing recently.

Slim joined the YASME DXpedition of Lloyd and Iris Colvin while in the British Virgins and helped fill the log of VP2VDJ. So far, he hasn't forwarded copies of his logs.

The ARRL is running some two months behind in processing DXCC applications. Enclose an SASE and you will at least know your cards arrived safely.

Congratulations to the new officers of the Arkansas DX Association: AF5M/President, W5LQN/VP, K5OVC/Secretary-Treasurer, and K5YY/Executive Committee.

W3KVQ, the long-time QSL manager for 9N1MM, has changed calls and QTHs. He is now Edward Blaszczyk N7EB, 12802 Sun Valley Drive, Sun City AZ 85351.

Although 160 meter operation is not officially allowed in Guatemala, you will occasionally hear a station on. Apparently, as long as the operator is careful about avoiding interference, the signal will not be noted. Guatemala also maintains a ban on phone patches.

A group of USSR types was supposed to head out to Franz Joseph Land last April. If you need FJL and you hear UK1PAA, UK1PAT, or possibly R1FJ, you will know they arrived.

The station at YI1BGD now has both the FT-101E and

Jun JA2BJW and his nice station. Jun prefers CW because he is fascinated by the prospect of communicating his mind to others through intermittent tones rather than ordinary language. (Photo courtesy of N9YL.)

FTDX-500 on line and has asked permission to operate other bands and to establish more stations. Meanwhile, it continues to be heard regularly on twenty.

The Southeastern DX Club shipped a remote vfo to A51PN, which has been making the operation a bit easier for Pradhan.

The first USSR amateur radio meeting took place last December in Moscow, with over 200 of the locals showing up. They are hoping for 160 permission with a 10-Watt input. A special "EU" prefix will be used during the summer Olympics to be held in Moscow next year.

Later word has it that K1RH also worked that BY1AA station we mentioned a few items back. Ralph notes that Pyng gave his QTH as Pecinng and that a check with some language experts at Yale indicated this to be an acceptable way of spelling Peking. Ralph caught the station on 28023 at 1455Z. K1RH, like ON4QX, awaits the China mail.

N5KC recently received a direct QSL from VR6TC for a QSO in August, 1973. Never give up.

K5MK resigned as QSL manager for 8P6JD, citing an inability to get the station logs as the reason.

CO2FA is looking for 160 action. He has a 75-meter antenna and can usually be found around 3800. Sometimes CW, sometimes SSB.

Fernando says that if you sent a QSL for a CO2FA contact and do not receive one in return within six months, you should try again. The mail sometimes takes three or four months getting to Havana and there appears to be little way to speed things up. Fernando also mentions that IRCs have little value in Cuba and that a green stamp works much better.

There apparently will be a flood of individuals and groups heading to the Isle of Man during June and July to operate during the celebration of the 1000th anniversary of the Isle of Man parliament, "Tynwald." Look for the GT prefixes.

Bill Rindone, who hasn't been heard from since he was the first to bring DXCC attention to the southern Sudan, STØ, reports that he will be heading back out again this summer. He will be aiming for the East Africa and Indian Ocean area, and more information should be forthcoming soon. You might remember Bill as the last person to activate Geyser Reef before it was deleted from the DXCC countries list.

If you like six meter DX—and there is quite a bit of F-layer stuff around these days—monitor 28885, where news is passed and schedules are made.

RF6F, heard in the CQ DX Contest last fall, was the Radio Club of Voroshilovgrad there in Georgia. Their effort netted 7.8 million points on SSB and 5.9 on CW. The club callsign is UK5MAF, and they are reported to be readying another multi-multi operation for the WPX contest, possibly signing R5M.

VU2KB, often found on 14 MHz CW, is an avid stamp collector and is interested in swapping with like-minded W/K DXers.

John Kanode N4MM has resigned his duties with the W4 QSL Bureau after four years of volunteer labor. John handled the W4/K4/N4 section of the bureau. His duties have been taken over by John Boyd W4WG, with the address remaining the same.

3B8DA is considering another 3B6 effort this summer. Nothing definite at this time, but we will let you know as plans progress.

Last month, we reported on the planned activity by Bruce Frahm KØBJ from the *Yankee Trader* on its ninth world cruise. We have obtained a copy of the ship's scheduled stops and will be reporting these each month. Stops in May include Samoa and Fiji.

The Gilbert Islands will become independent this July. Look for a new prefix to replace the present VR1. Meanwhile, VR1BD can usually be found around 28503 kHz from 2000Z.

9M8HG passes along his sincere thanks to the many DXers worldwide who sent get-well cards during his recent illness. Some W/K DXers donated a new 300-Watt rig and beam to replace Horace's little 80-Watter and dipole. He frequents 21320 kHz at 2200Z and then drops down to the 14225 kHz net at 2300Z. Horace, now 82, was first licensed in 1924 as OB2SK. He won the world DX Contest in 1932, running 5 Watts.

OE6EEG is reported to have forwarded the necessary HZ1BS/8Z4 documentation to the DXCC desk.

A team led by KH6CHL will activate rare Kalawao county on 10 through 80 meters from May 25th to the 27th.

The E/W DX Net which meets each Thursday on 14248 kHz at 0500Z continues to be a gathering spot for Pacific and African DX types.

George Collins VE3FXT will be on hand September 6th to help Vendaland celebrate its Independence from SA. A tower is being erected (equipment was left on an earlier trip).

Lloyd and Iris Colvin report making 6,000 contacts from W6KG/TI5 in Costa Rica, split

VU2VKK, in the center, visits with VU2GO and VU2GX while the latter wait in vain with the rest of the VU4ARC Laccadive DXpedition crew for operating permission that never came.

LETTERS

TARA SINGH XZ2KN

I am sending a picture of my late father, Tara Singh XZ2KN. This is the latest picture I have of him, taken just last year. This was taken in Pegu, about 60 miles out of Rangoon. The statue of the Reclining Buddha is the background.

My father was born in Kalaw, Shan States, Burma, in 1918 and was educated in Rangoon. He graduated with a BS in Mechanical Engineering from Rangoon University. He was a very active sportsman and became golf champion twice. He also represented Burma abroad many, many times. He got his amateur license in 1938 and was very active. Soon after, due to WWII, he evacuated to India with his family. They walked to India, a trek which took over 3 months. He had tied his radio equipment to the rafters in the attic to prevent damage in his absence. He was a contractor and was instrumental in building the Burma-China railway before evacuating. On his return, he helped my grandfather with the machine-shop and foundry business. Known as the Empire Foundry, it was one of the largest in Burma. He was an avid believer of the good antenna over high power theory and, having the resources, always was building new antennas. At one time, he built a 4-element wide-spaced beam for 20 meters with a 44-foot boom. The boom used 1" x 1" x ¼" angle iron, and the beam assembly weighed about 2000 pounds. He then got infatuated with cubical quads. The last antenna he built was a 4-element quad, with which he had excellent results. He used an AR-88 receiver and, when he could get it working, an ET-4336 transmittter.

The last rig we used was a Johnson Viking Ranger running 65 Watts—yes, 65 Watts into a 4-element quad. We made many, many stateside contacts and never had trouble or felt inadequate. As no new licenses were being issued, I was the second operator for XZ2KN. Amateur radio was banned on 10 January 1964, and no one has legally operated after that date. The licenses are renewed every year, but with specific instruction not to use the equipment which has not been confiscated. I might mention that my father was the Secretary/Treasurer of the Burma Amateur Radio Society for as long as I can remember. My father was hit by a car while crossing a street on 11 February 1979 in Rangoon. He died in the hospital on the 12th and was cremated on the 13th.

Gurbux Singh WB9TTN
Rochester IL

P.S. In his last letter, received a week before his death, he wrote that amateur radio was certainly out and that he saw no hope for it in the future.

Tara Singh was most accommodating when I visited Rangoon, taking the time to show me all around the city so that I could take pictures, introducing me to the British Ambassador (there was no U.S. embassy in Burma), and filling me in on the history of this most interesting country. It was during this short visit that I met Gurbux, his son. While visiting Singapore a few days later, I sent Gurbux some strings for his badminton racquet via a local ham, also named Singh. Eventually, Gurbux had to leave Burma, and the only address he had was 9V1NR in Singapore, who had forwarded the strings for me. The next I heard, Gurbux was marrying 9V1NR's daughter and moving to the U.S. Quite a world! I was saddened to hear that Tara had passed away without ever getting back on the air again, for I remember how his eyes lit up when he talked about amateur radio . . . a true love of his.—Wayne.

Tara Singh XZ2KN.

IMPRESSED

I'm sorry I haven't written earlier to praise you and your staff for publishing the finest amateur magazine in America. You may not remember me, but my wife and I visited you at your station on Mt. Monadnock before we were married . . . I think it was in 1965 or so . . . back when W2NSD/1 was so strong down here in New Jersey on two meter AM that you could take out most of the locals on my old Gooney box.

I've always been impressed by your sincere devotion to amateur radio, and I read your editorials with interest each month. I ditto your comments about Sam Harris in January *73*. Sam was one of my first two meter "DX" contacts, back when 250 miles was a long haul on that band, and Helen was my first Puerto Rican contact on six meters. He will be missed.

Please keep up the good work, and pray with me that post-WARC '79 days will give you a reason to continue publishing an amateur radio magazine!

Steve Katz WB2WIK
Budd Lake NJ

LOYALISTS

From reading your editorials, which I tend to agree with as well as enjoy immensely, it seems to me that there is more than enough evidence to firmly establish the fact that the ARRL is detrimental to the future of amateur radio. When something doesn't function properly, it should either be repaired or discarded; this is the case with the ARRL. Since it is operated in such a manner as to make repair nearly impossible, then, in my opinion, it should be done away with.

I do not agree with the "but it's all we've got" philosophy. As long as the ARRL exists, it is "all we'll have"—they'll see to that! You always make the point that you've been a member of the ARRL for most of your ham career; I fail to see the logic in spending $12 a year to support something I can't believe in. Were you to quit the ARRL, in protest, chances are that 50,000 hams would do likewise and the ARRL would fall in to that degree—or do you have 50,000 loyal followers? Might be interesting to find out.

More than half the hams I have queried about their reasons for joining the ARRL tell me that they "take the magazine," "just joined to get *QST*," etc. That is why I would never subscribe to *QST*—I don't want to be "represented" by the ARRL, at WARC '79 or anywhere else. If we did have a truly representative amateur radio organization, I would endeavor to join and support it. As I've said before, why don't you and some of the prestigious hams who are *73* loyalists resurrect the Institute of Amateur Radio? It's high time!

Bill Harris K9FOV
Lafayette IN

Bill, as far as I know, I have no loyal followers . . . and I don't want any. If anyone agrees with what I write, I want it to be on the basis of intelligence, not reaction and emotion. If I were to drop out of the ARRL, I doubt

Contests

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

NEW YORK STATE QSO PARTY
Starts: 1700 GMT Saturday, May 5
Ends: 2359 GMT Sunday, May 6
(with a rest period between 0500 and 1200 GMT on May 6)

Sponsored by the University of Buffalo ARC, WA2NPQ, this contest is open to all amateurs. Stations may be contacted once on phone and once on CW on each band. NY stations may work each other and mobile/portables changing counties may be reworked.

EXCHANGE:

QSO number, RS(T), and NY county or state/province.

FREQUENCIES:

SSB—3900, 7275, 14285, 21375, 28550.

CW—1810, 60 kHz up from the bottom of each band.

Novice—3725, 7125, 21125, 28125.

SCORING:

Score one point per QSO times the number of multipliers: states, provinces, countries, and NY counties for NY stations, or the number of NY counties for others (62 max.). Note that this is the first time NY stations may include NY counties in the multiplier total.

ENTRIES & AWARDS:

All entries must contain name, address, and county (if NY). Number the first contact for each new multiplier. A checksheet is required for stations making more than 100 QSOs. Awards to the number 1 score from each county, state, or country. Entrants desiring results please send a #10 SASE. Logs must be received by June 16 to qualify. Send all entries to: Michael Bergman WD2AJS, 45 Swartson Ct., Albany NY 12209.

FLORIDA QSO PARTY
Starts: 1500 GMT Saturday, May 5
Ends: 2359 GMT Sunday, May 6

This is the 14th annual Florida QSO Party sponsored by *Florida Skip* and all amateurs worldwide are eligible and invited to participate. Each entrant agrees to be bound by the provisions of this announcement, the regulations of the applicable licensing authority, and the decisions of the *Florida Skip* Contest Committee, which are final. All amateur bands may be used and all stations will separate phone and CW logs! A station may be worked once on each band on each mode. Neither crossband nor crossmode contacts will count for contest credit. Florida stations may work other Florida stations, but for QSO points only. Out-of-state stations may not work each other for contest credit. Contacts made on repeaters do not count! Florida stations will be divided into two classes: Class A stations are those operating portable or mobile on emergency power and running 200 Watts or less inside Florida but outside of their home counties; Class B stations are all other stations operating inside Florida.

EXCHANGE:

RS(T) and Florida county or state, province, or country. Out-of-state mobile stations operating not within the jurisdiction of any country send ITU region (1, 2, or 3) in which operating.

FREQUENCIES:

CW—355, 7055, 14055, 21055, 28055.

Phone—3945, 7279, 14319, 21379, 28579, 146.52.

SCORING:

Florida stations count 1 point per QSO with out-of-state or other Florida stations and multiply by the sum of states (49 max.), provinces (12 max.), DX countries (15 max.), and regions (3 max.) actually worked. Maximum multiplier is 79. Out-of-state stations count 2 points per QSO with each Florida station and multiply by the number of different Florida counties worked (67 max.). Class A Florida stations *only* multiply score by 1.5 to obtain final total.

AWARDS:

Certificates for phone and CW top single-operator score in each state, province, DX country, and each Florida county. There are also five plaques to be awarded as follows: high single-operator Florida and out-of-state, CW and phone, and to the Florida club with the highest aggregate score.

ENTRIES:

At the direction of the contest committee, stations and/or operators may be disqualified for improper reporting, excessive dupes, errors in multiplier lists, unreadable logs, obvious cheating, etc. Anyone disqualified in this year's Florida QSO Party will be barred from the contest next year. Phone and CW entries are to be separated. Along with legible logs in chronological order, a summary sheet is required with each entry. The summary sheet must contain score, number of QSOs, multiplier, station's callsign, entry class and county of Florida entries, power score for Class A entries, state/province/country/region for out-of-state entries, callsigns of all operators/loggers if multi-op, name of club if part of a club aggregate score, name and address typed or printed in block letters, and a signed declaration that all rules and regulations have been observed. Include a 15¢ stamp for contest results from a future issue of *Florida Skip*. All entries must be received on or before May 31, but late DX entries will be accepted within reason. Mail entries to: *Florida Skip* Contest Committee, PO Box 660501, Miami Springs FL 33166.

LIARS 10-X QSO PARTY
Starts: 0001 GMT Saturday, May 5
Ends: 2359 GMT Sunday, May 6

Sponsored by the Long Island Amateur Radio Service (LIARS) Chapter of the 10-X International Net. The object of the contest

is to contact as many stations as possible on 10 meters, 28.9 to 29.2 MHz.

EXCHANGE:

Station call, name, QTH, and 10-X and LIARS membership numbers.

SCORING:

Score 1 point per contact; only 2-way QSOs are valid. Add 1 point for each 10-X number and 1 point for each LIARS number with a maximum of 3 points per exchange.

ENTRIES & AWARDS:

Only 10-X members are eligible for awards. A first- and second-place certificate to each state, province, or DX foreign country. A first-place trophy to highest scoring participant holding a LIARS number. Any clear method of logging will be acceptable. Include your LIARS number, if any. Send a copy to: Bob Watson, 2 Suffolk Court, Oceanside NY 11572. Please include an SASE if a copy of the results is desired. Logs must be received by June 15.

LUCKENBACH DXPEDITION
0800 May 12 to 1200 May 13, 1979 Central Standard Time
Callsign: W5TEX

The idea of a "Luckenbach Dxpedition" began as a joke between several stations, including WB5VDL, KB5DV, WB5ROQ, N5AOW, and AI5Q, in early December of 1978. During the course of operating around the bands, they found many amateurs had not only heard of Luckenbach, but also looked forward to working a station there.

Luckenbach, located in the heart of the Texas hill country, was brought to national attention by a country/western hit song by Willie Nelson. It is a town virtually untouched by modern civilization and is nestled between two small rivers. It boasts a general store, one house, and a barn. Their first pay telephone was just installed late last year. It is not uncommon to drive the only street in town and have to stop for the cows to cross.

To make this area available to those desiring a QSO, W5TEX will be operating during the dates/times shown above with a special QSL certificate to commemorate the event. To receive the certificate, stations should send a legal size (4" x 9½") SASE to W5TEX, 2618 Rigsby, San Antonio TX 78222. Only QSOs confirmed by W5TEX logs will receive the certificates. The certificates will be 8½" x 11", printed tricolor on bond paper, and should be a welcome addition to any shack.

Operating frequencies are: CW—7110 and 21110 ±5 kHz; FM—52.525, 29.600, and 146.52; SSB—3900, 7235, 14285, 21360, 28625, 50.110, 144.200, all ±5 kHz.

Kennedy Associates, the South Texas Yaesu dealer, has kindly provided Yaesu radios and station equipment, while antennas will be furnished by Wilson Electronics for this special operating event.

WORLD TELECOMMUNICATIONS DAY CONTEST
Phone
0000 GMT to 2400 GMT
May 12
CW
0000 GMT to 2400 GMT
May 19

This contest, sponsored by Liga de Amadores Brasileiros de Radio Emissao (LABRE), was instituted in order to commemorate yearly "World Telecommunications Day" (May 17). Each participating radio amateur will attempt to make the highest possible number of contacts with the different ITU zones of the world in order to enable his country to win the ITU Trophy. Use all bands 80 through 10 meters on phone and CW. Categories include: 1) single operator—multiband; or 2) radio clubs and associations—considered as special multi-operator/multiband participants.

Points are computed separately, certificates being awarded to the top winner in each country on each mode, phone and CW. To the world top winner on each mode, a silver plate.

EXCHANGE:

RS(T) and ITU zone.

SCORING:

In the same country, any band = 0 points (same country considered as same ITU zone); in another ITU zone/country: in the same ITU zone, but different country = 1 point (any band); in another ITU zone, on the same continent = 3 points (any band); in another ITU zone, on another continent = 5 points (any band). Final score is the sum of QSO points multiplied by the number of ITU zones worked. Repetition of contacts with the same station on different bands will be permitted though each ITU zone must be counted as a multiplier only once.

For this contest, what constitutes a country will be determined by the ARRL DXCC list. In order to obtain the number of points for a country, on each mode of operation, the sum of points earned by the top 5 contestants of the country will be taken. In the case of less than 5 entries from a given country, the sum of points of the submitted logs will be taken. Points earned by participants considered as clubs or multi-operators will not be valid for country points sum.

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

This month, we complete the second year of RTTY Loop. I must say that it has been, and continues to be, a real thrill to be able to share so many facets of RTTY communication with you all. We have covered a lot of ground in these past two years. Early columns started with the basics of teletype™ circuits, and lately we have worked into digital logic systems. This month, we will dip into the bulging mail sack, in no particular order, to answer, respond to, or pass along some of the thoughts that have been sent in to me.

Starting out on a somewhat oddball vein (but that's routine for this column), I have a letter from Jerry Keefe W0HAQ. Jerry has an SWTPC 6800 computer and a KSR-33. The KSR-33 was apparently used in Britain with a non-standard interface. Jerry, the teletype should directly interface with the serial (MP-S) interface of the SWTPC 6800. You have sent along a circuit, reproduced as Fig. 1, that was given to you as an "RS-232 interface." By my unskilled but logical eye, there is definitely something wrong here! Any readers willing to commit themselves may write their opinion and I will pass it along to Jerry. In the meantime, it might be worth your while to try to get the "standard call control unit" that will turn your ugly duckling into a beautiful swan-etype.

Speaking of computers (how's that for transition), Dave Ewing WB9PHQ sends along word that he is up and running with a bare KIM-1 and homebrew 567 decoder. Sounds interesting, Dave. Send along some details and we will try to spread the word to other KIM and 6502 owners.

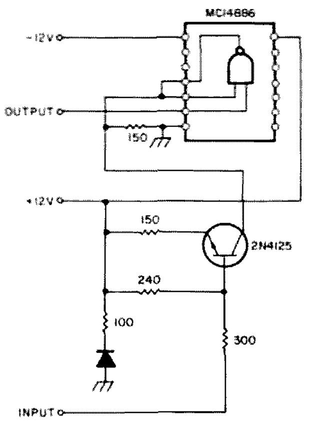

Fig. 1. W0HAQ's mystery circuit.

George Young K4SDG is another SWTPC 6800 owner who is trying to get a system up and running on RTTY. George asks about ASCII-to-Baudot conversion in hardware. Well, I would rather do the conversion in software, as the receiving program of last year shows, but, if you are insistent, *73* has published several good hardware conversions in the past few years. One which comes to mind rather quickly was an ASCII-to-Baudot converter described by Cole Ellsworth W6OXP on page 52 of the February, 1976, issue of *73*. This design converts all ASCII characters to the corresponding Baudot character, filling characters which have no match with a Baudot blank. While you're looking at that article in the magazine, you might want to check out the cover story, too. It's out of this world.

One of those things we all like to do is try to copy some of the commercial and press RTTY transmissions for personal enjoyment. Bob Magill WA6MUG is one of several readers interested in such information. I would be willing to compile some sort of list, if any data is available. Readers with information on commercial, press, etc., RTTY transmissions are asked to jot down times, frequencies, shift, speed, ASCII or Baudot, and send them to me at the above address. I'll try to present some useful form in the future.

Some more inquiries have come in on the Microlog RTTY system. To Lee Lust WA2ETQ and the others who have asked my opinion by mail and via other media, all I can do is reiterate what I said a few months back. As of this writing (March, 1979), data promised me in October, 1978, has not arrived. Several hams have used the system, and, while it appears to perform as advertised, it *is* rf-sensitive. If you have any rf around the shack, as with a high swr, you may have trouble. Caveat emptor.

A quick QSL to Clifford Erback VE5QY up there in Moose Jaw, Saskatchewan, Canada. With a Model 15, Flesher 170, and FT-101E, he has quite a nice RTTY station. The F1200B linear and TH6DX beam only help to get him into those "gray areas," right Cliff? Tom (no last name) WB8BDG is another member of the kilowatt club who feeds his TR4 into a MLA2500 linear. Teletype Model 15 and 14 equipment provides the green key interface, along with a HAL ST-5. The last member of this month's teletype group is Howard Olson WA9KEK, whose RTTY equipment consists of a Model 19 feeding either an Icom 245 for two meter RTTY or an NCX3 for HF work. While the abundance of hams on RTTY are using equipment produced by the Teletype Corporation, and most of those are using Model 15/19 setups, there is no clear consensus.

The second most popular machine is usually a product of the Kleinschmidt manufacturing concern. R. B. Gober, DDS W5ZNN writes of the Corsicana Teletype Society. It seems he and another member, N5ALA, are working on a few Kleinschmidt Model TT-100B-FG machines. Also laboring on one of these is Rob Lawson WB4BSZ, who is sweating over a TT-117-FG. Anyone having good wiring and application material is invited to send it along to this column to help get these and other fraters out of a jam.

Along the lines of the press transmissions mentioned earlier, Rob raises the possibility of copying weather data from stations located down south where he lives. Any data on these stations would also be handy.

Some of you may question why I take the space to run down this or that ham's gear, Teletype, computer, etc. When I was new to RTTY, or ham radio in general, I was frequently confused by the vast (at *that* time) proliferation of equipment and systems. Now, here we are in an age of sophistication. Model 99s, 6880 computers, and LSMFT rush into the novice's vantage and mingle into an amorphous blob. What I hope to do is show, by example, what hams are using now on the air. Hopefully, the old and the new will integrate into a unified scheme and the newcomer will be a little better informed when someone offers him a "slightly used Model 12." So much for philosophy.

Next month, we will begin the third year of RTTY Loop as we began the second—exploring the computer in RTTY. I will present a transmitting program for the SWTPC 6800, using a parallel port for output. As with the receiving program of last year, flowcharts will be included to allow adaptation of this program to other systems. Until then, keep on loopin'!

Ham Help

We are presently setting up a School of Communication here at Toccoa Falls College, Toccoa Falls GA. Being a ham, I have presented the possibilities of amateur radio as a way of communication. We have been given a room and space for antennas. Some of the students have already started working on code and theory. We are now looking for good used equipment for the club station. Any donations of such equipment will be appreciated. Tax-deductible receipts will be given for the good equipment.

We also have a Nagra III Swiss-made tape recorder for which we need a manual. If anyone has one, we would like to copy it. We would buy one if an address can be given as to where to write.

Any help given will be appreciated.

Dale McMindes KA4HBW
Toccoa Falls College
Toccoa Falls CA 30577

I need plans for a 2m duplexer that we can build for our club repeater. We would be interested in buying a used duplexer if someone has one.

Canton OH 44706

I am in need of a Shure M-5D monaural phono cartridge for an experimental circuit. I called the warehouse in Evanston, Illinois, and Shure does not have this in stock anymore. Are there any special shops that might stock hard-to-get parts like this? Fellow amateurs seem to be the only source of help. I will gladly pay up to $20.00 for one from someone's junk box.

New Products

SINCLAIR PDM 35 DIGITAL MULTIMETER

Although around for a few months, the Sinclair PDM 35 digital multimeter is a very versatile unit, considering its compactness, and the price is right! In fact, it may be the lowest-priced commercial pocket digital multimeter on the market.

The PDM 35 provides a very bright reddish-purple 3½-digit display reading to ±1.999. Polarity of the display is automatic and resolution is within 1 mV and 0.1 nA (0.0001 uA). The decimal point is fixed, so it is necessary to mentally extrapolate readings depending upon the range selected. For instance, when the display shows 0.987 and the multiplier switch is on x100, the digits are read as 98.7.

Dc input impedance is 10 megohms for four ranges of dc voltage to a maximum of 1000 volts. Accuracy in this mode is 1.0% ±1 count. A single ac voltage position (40 Hz to 5 kHz) permits readings up to 500 volts rms, accurate to 1.5% ±2 counts, with an input impedance of 450k Ohms. Six current positions switch from 1 nA to 200 mA. Five resistance ranges permit accurate readings from one Ohm to 10 megohms, also with 1.5% accuracy. Five additional junction-test ranges are also available.

The instrument measures resistance by forcing a known constant current through the resistor and measuring the voltage developed. It is possible, using the resistance ranges on the meter, to measure the forward voltage drop of semiconductor junctions and to match the V_{be} of transistors. The current used corresponds to the current range scale, and the display reads the forward voltage drop in volts.

Measuring only six inches by three inches by 1½ inches thick and operating on a single nine-volt battery, the PDM 35 is ideal for use away from the bench. However, on the negative side, I found that the test leads and, more especially, the test lead sockets detract from an otherwise outstanding unit. The leads are stiff and kinky, and inserting and removing the plugs in the sockets is extremely difficult due to the mechanics of both the plug and socket. This is distracting because mode switching is not employed for DCV to ACV to mA/Ohms, and one test lead must be re-inserted for each mode.

With the exception of the x1000 volts dc range and the ac position, all ranges can be used to a maximum displayed value of ±1999. Exceeding this will display ≡000, or =000, indicating that the next higher range should be selected.

The operating instructions accompanying the multimeter are complete and adequate. A schematic in this booklet is barely legible because of size, even with the use of a 10X magnifier. No parts values or type numbers are shown on the schematic—only component reference designators. Because neither a parts list nor a theory section is provided, these designators serve no purpose.

The PDM 35 comes complete with test leads, soft carrying case, and instruction book. An ac adapter, 30-kV probe, and padded case are extra-cost items. Guarantee period is one year.

TRAC DELUXE CMOS ELECTRONIC KEYER

Trac Electronics, Inc., has introduced an addition to its line of state-of-the-art CMOS keyers. The Trac Deluxe CMOS Electronic Keyer, Model TE 144, contains all CMOS integrated circuitry. The front panel contains controls for speed, weight, tone, and volume. In addition, a rear-panel switch allows "bug"-type operation (automatic dots, manual dashes) as well as straight-keying operation. The Deluxe CMOS Electronic Keyer provides both dot and dash memory, iambic keying, 5-50 wpm, sidetone, and speaker, all housed in an eggshell-white base and woodgrained top. It is compact in size, 6" x 4" x 2". The unit is operated on a single 9-volt battery and keys both positive- and negative-keyed rigs. Available direct from *Trac Electronics, Inc., 1106 Rand Building, Buffalo NY 14203*, or at most dealers throughout the US and Canada. Reader service number T18.

DAIWA RF-440 RF SPEECH PROCESSOR

It was the acid test for my brand new Daiwa RF-440 rf speech processor: nighttime phone operation on 75 meters. Would the RF-440 really help my low-power signal punch through the bedlam? My CQ was answered by a station in Pennsylvania. After the usual exchange of pleasantries, I asked him to evaluate the performance of the RF-440 while I switched it in and out. The result of this mini-test? "Without the processor, you were down in the mud; I couldn't copy anything. With the processor, I copy 90%." That was enough for me. I was hooked.

Since that first night, I have used the RF-440 in a variety of situations. While the results are not always as dramatic as the instance cited above, the processor has yet to disappoint me.

The RF-440 is designed to increase "talk power" without introducing distortion and splatter. It's packaged in a very attractive all-metal enclosure that is several cuts above the cheap-looking boxes used by some accessory manufacturers. The small size (6" x 2½" x 6") of the unit and the smooth feel of the controls give the RF-440 the aura of a precision watch. It's solid.

The RF-440 simply installs between your microphone and transceiver. It comes pre-wired for Kenwood equipment, so I had to swap connectors to use it with my Heathkit gear. The processor has an internal ac power supply, but it also operates from 12 V dc for mobile use.

Using the RF-440 is a pleasure. Simply set the gain control for a proper level using the built-in meter, then adjust the output control so as not to overdrive your rig. I adjusted the output control using an oscilloscope, then went on the air and was told that my signal sounded fine, with no distortion. Alternatively, you could start with the control set at its midpoint, then solicit on-the-air opinions for a final adjustment.

One school of thought says that speech processor controls should be inside the case so you can set them and forget them. As a confirmed knob-twiddler, I was pleased to see the controls of the RF-440 right there on the front panel where they belong. This really simplifies matters if you intend to use the processor with more than one microphone or rig. Another convenience is an "OFF" position on the gain control which bypasses the processor for straight-through operation.

The impressive Daiwa product line is being distributed in the USA by the *J. W. Miller Division of Bell Industries, PO Box 5825, Compton CA 90224.* Reader service number B47.

Sabtronics' model 2010A.

YAESU INTRODUCES THE FT-101ZD

Yaesu Electronics Corporation of Paramount, California, is pleased to announce the introduction of the FT-101ZD transceiver.

The FT-101ZD is all new in design and offers many of the features of the internationally acclaimed FT-901DM.

The FT-101ZD is a no-compromise HF SSB/CW transceiver which offers variable i-f bandwidth for 2.4 kHz to 300 Hz, digital plus analog display, built-in rf speech processor, a built-in ac power supply, a new highly effective noise blanker, rugged 6146B final tubes, all band coverage 160-10 meters, WWV, plus WARC band expandability and a true frequency counter (no more recalibrating when changing modes).

Additionally, the FT-101ZD is compatible with all of the FT-901DM accessories.

The FT-101ZD is now available from your local Yaesu dealer. *Yaesu Electronics Corporation, 15954 Downey Ave., PO Box 498, Paramount CA 90723; phone (213)-633-4007.* Reader service number Y1.

HIGH-SPEED DIGITAL OPTO-COUPLERS FOR 5-VOLT LOGIC INTRODUCED BY MOTOROLA

Motorola has introduced two fast, low-cost, digital optocouplers for 5-volt logic applications. Designated the MOC5005/6, they offer 7500-volt peak ac isolation and are UL-recognized.

The new high-speed optocouplers' turn-on time is 225 ns (typical) for the MOC5006 and 420 ns (typical) for the MOC5005. The two devices are TTL compatible and are designed for applications requiring very high electrical isolation, fast response time, and digital logic compatibility. Such applications include interfacing computer terminals to peripheral equipment, interfacing with microprocessors, digital control of power supplies, motors, and other servo-machine uses.

Designed as a digital converter, the application of current to the LED input results in a low voltage output; with the LED off, the output voltage is high. The circuits are current-, voltage-, and temperature-compensated and will sink an eight-gate fan-out (13mA) from DTL, TTL, or CMOS with an applied power supply voltage of 5 volts and 16 mA applied to the input. The units offer built-in hysteresis and internal pull-up resistor and feature low power consumption of 4 mA (typical) @ 5 volts in the ON state.

Delivery is from factory stock and authorized Motorola distributors. *Motorola Semiconductor Products Inc., PO Box 20912, Phoenix AZ 85036; phone (602)-244-6900.* Reader service number M20.

NEW LOW-COST 3½-DIGIT DMM OFFERS TOUCH-HOLD FACILITY

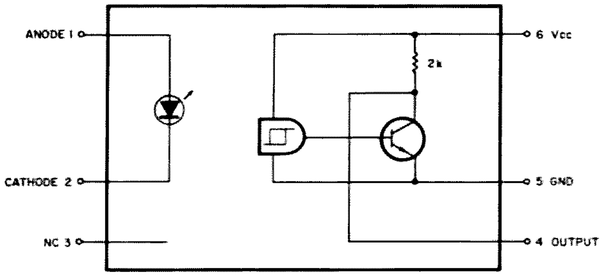
Sabtronics International of Dallas, Texas, has introduced a new low-cost bench/portable 3½-digit DMM that features touch-and-hold capability with an optional test probe. This permits retaining the display's reading even when the probe is removed from the circuit. The model 2010A DMM provides standard ac, dc, and high/low-power resistance measurements in 31 ranges.

The model 2010A DMM is designed for current measurements up to 10 Amps (ac or dc), with an ac frequency response from 40 Hz to 50 kHz, and with an input overload protection to 1200 V dc or rms on voltage ranges. A unique feature of this DMM is a "times 10" multiplier switch for convenient setting to the next higher decade range.

Single-chip LSI circuitry is the basis of this compact unit; the display is made up of large LEDs that read to ±1999 with automatic decimal point. The manufacturer has incorporated a stable bandgap reference for long-term accuracy and states that typical DCV accuracy is 0.1% ±1 digit. Other features of the unit are automatic zeroing, fuse protection on Ohm and current ranges, automatic polarity, and overrange indication.

Optional accessories for the model 2010A include a touch-and-hold probe for measurements in hard-to-reach places, a high-voltage probe, rechargeable nickel-cadmium batteries, and an ac adapter/charger. All are available from Sabtronics.

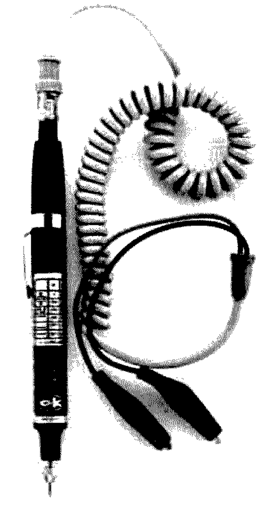
The model 2010A may be ordered directly from the manufacturer. Write *Sabtronics International, 13426 Floyd Circle, Dallas TX 75243; phone (214)-783-0994.* Reader service number S27.



MOC5005/6 digital optocoupler schematic.

10 NSEC LOGIC PROBE IS LOW COST

The new PRB-1 digital logic probe costs less yet offers the full features of much more expensive probes. It detects pulses as short as 10 nsec and has a frequency response to 50 MHz or better. The unit provides automatic pulse stretching to 50 nsec (+and −) and is fully compatible with all RTL, DTL, HTL, TTL, MOS, CMOS, and microprocessor logic families. It also features 120k-Ohm impedance, power lead reversal protection, and overvoltage protection to +70 V dc. Constant brightness LEDs are provided over the full supply voltage range of 4-15 V. There is an optional PA-1 adapter for use with supply voltages of 15-25 V. Included are a six-foot coiled power cord and tip protector. The unit comes neatly packed in



OK's PRB-1 digital logic probe.

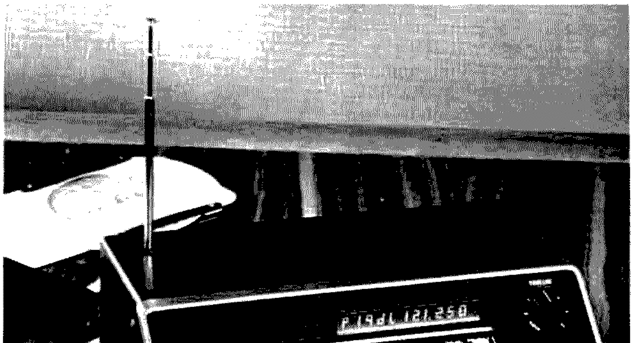
"BEARCAT® 220" SCANNER RECEIVES AM AIRCRAFT BAND PLUS FM PUBLIC SAFETY BANDS

Electra Company has announced a breakthrough development in scanner technology that allows a single scanning monitor to receive not only public safety, marine, ham, and other FM frequencies, but also the AM aircraft frequencies. The new Bearcat 220 scanner is the first scanning monitor which combines AM and FM reception capability. Until now, two of the most popular monitoring activities—listening to aircraft and listening to police calls—had to be received on separate monitor receivers. But now, six VHF and UHF FM public service bands plus the AM aircraft band are covered by this single radio.

The new Bearcat 220 also features three search operations for finding active local frequencies. It has the normal search operation where frequency limits are set and the scanner searches between them. All active aircraft and marine frequencies are preprogrammed into the scanner's search memory so frequency limits aren't necessary. The user simply pushes the aircraft or the marine search button and the BC 220 seeks out the aircraft or marine frequencies being used locally.

Crystal-less push-button frequency entry which was pioneered in the Bearcat 210 scanner is used in the Bearcat 220. The actual frequencies being monitored are shown on a bright digital display. Up to 20 frequencies can be in any sequence or mix of bands. A priority function is also provided, instantly alerting the listener when a call is made on the priority frequency programmed into the channel one position. Channels can also be activated in banks of 10, permitting the operator to "call up" a group of 10 channels with one push-button.

Other features included in the Bearcat 220 are patented selective scan delay, scan speed selection, ac/dc operation, automatic and manual squelch, individual channel lock-out, and direct access to any programmed channel without the need to manually step through channels. Electra Company's patented "track tuning" is used to provide optimum reception across entire frequency bands. Complete details are available from Bearcat suppliers or by writing to *Electra Company, PO Box 29243, Cumberland IN 46229.* Reader service number E40.



New Bearcat 220 scanner.

PACE'S COMMUNICATOR II

Pace Communications Division of Pathcom, Inc., has been known for its superb CB and commercial FM two-way radio products for many years. A few months ago, the Amateur Radio Products Group of Pace introduced its Communicator line. Top of the line is a 4-MHz, 800-channel, all-synthesized two meter FM mobile, the Communicator II.

By using three knobs (MHz, 100 kHz, and 10 kHz) and an in-out push-button for 5 kHz, the receive frequency is rapidly dialed into the unit and displayed on the .375" 6-digit LED readout. Transmit is selected by a 5-position rotary switch giving simplex, ±600-kHz, and ±1-MHz splits. When the PTT is depressed, the digital readout automatically shifts from receive frequency to transmit frequency, leaving no doubt as to where the unit is set. Also of note is a push-on, push-off power switch that relieves the user of having to reset the volume control. The Communicator II weighs 6.6 pounds and is 6.4" W x 2.8" H x 10.2" L. Current draw is 1-1.5 A receive and 1.5 A (1 W)-6.0 A (25 W) transmit.

Using 52 diodes, 8 LED units, 32 transistors, 6 FETs, and 18 ICs, the Communicator II operates in a 16F3 mode. Power output is 1 or 25 Watts push-button controlled (with the 25 Watts being adjustable for those who wish QRP). Frequency deviation is ±5 kHz maximum. Spurious harmonics are 65 dB below carrier. Frequency stability is ±5 ppm for −30° to +60° C.

The receiver is a double superheterodyne using 16.9-MHz and 455-kHz I-fs. Sensitivity is less than .4 microvolts for 20 dB quieting (.20 microvolts for 12 dB SINAD). Image and receiving spurious rejection is 65 dB down; selectivity is 65 dB down at ±12 kHz. The internal 8-Ohm speaker allows 1.2 Watts at 10% THD. One of the 8-mm plug jacks on the rear mutes the internal speaker when an external speaker is connected. The other 8-mm jack allows not only an external speaker to be used,

SUBROUTINES AND STACKS

Subroutines are powerful software building blocks. They facilitate program development since they may be written and tested apart from the main body of software. In addition, they can be adapted for use with almost any type of program. In this month's column, we will focus upon their operation as well as on the use of stack instructions.

Both *unconditional* and *conditional jump* instructions transfer computer control to another software task starting at the sixteen-bit address specified within the jump instruction itself. The jump instruction is a one-way branch since it points to a single address, as illustrated in Fig. 1. In many software tasks, however, there exist short subprograms which are used repeatedly. Examples of such tasks include mathematical computation, control, and teletypewriter input/output routines. It seems wasteful to duplicate these subprograms throughout the main program, so an attempt is made to separate them at the end of the main program and, in some manner, branch to them when they are needed.

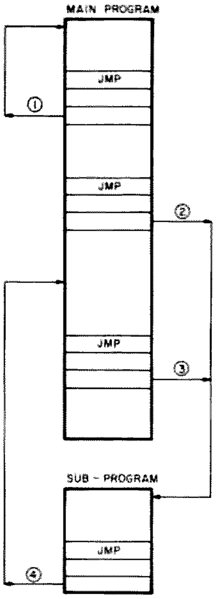

Fig. 1. Diagram illustrating the characteristics of the jump instruction.

The use of jump instructions to access these subprograms will not be successful since there will be no *link* back to the main program once the subprogram's task is completed. The use of an additional jump instruction at the end of the subprogram which points back to the main task is unsatisfactory, since jump instructions can point to a single address. This is also illustrated in Fig. 1. The jump instructions at 2 and 3 point to the same subprogram, but upon completion of the subprogram's task, the jump instruction at 4 can only provide a link to one place. A new operation, the *call* instruction, is required. This has the effect of inserting the subprogram's software steps in the main program flow at points 2 and 3, but without the problems associated with the use of a jump.

The call instruction, like the jump instruction, transfers control to another portion of the software. When that portion has completed its task, however, control is returned to the main program. This is illustrated in Fig. 2. In the figure, two subroutines are used by the main program, each being

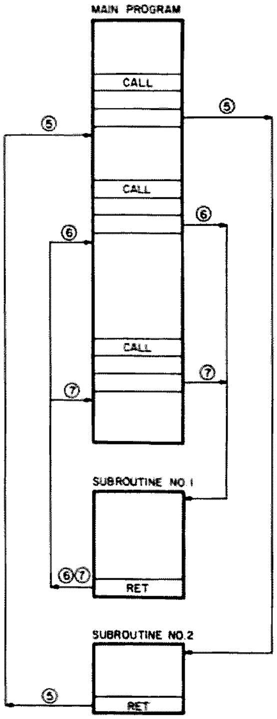

Fig. 2. Diagram illustrating the characteristics of the call and return instructions.

GLOSSARY

Subprogram: A section of a program which may perform a particular operation to be used with a larger program. Subprograms are not general-purpose and are generally used by one program.
Subroutine: A program which is general-purpose and which may be called or used by a main program or another subroutine.
Main Program: A short notation to indicate the software tasks which will occupy most of the computer's time.
Link: A pointer address which will point the computer to another section of a program or back to a program which it may not be currently using.
Nesting: The operation of one subroutine within another, e.g., a one-minute delay subroutine may call a one-second delay subroutine 60 times.

accessed by a call instruction which specifies the starting address of the subroutine as a sixteen-bit, or two-byte, word. *At the completion of the subroutine, control is returned to the next instruction which follows the three-byte call instruction.* Through the use of call instructions, the program shown in Fig. 2 has inserted the subroutine program steps in the flow of the main software task. Subroutine number 2 is used only once, but subroutine number 1 has been used twice although it is present only once in the microcomputer's memory.

Each subroutine is accessed via a call instruction and ends with a *return* instruction RET. The return is a one-byte instruction which does not contain any address information, yet it acts to return control to the main program. The return of control takes place since the call instruction saves a *linking*, or return, *address* which acts to branch the computer back to the address of the instruction immediately following the three-byte call. The return instruction causes the microcomputer to retrieve the address from storage and use it as the link back to the main task.

The sixteen-bit return addresses associated with call instructions are stored in an area of read/write memory called the *stack*. The transfer of address information is performed automatically by the 8080 microprocessor chip to and from the stack during call and return operations. Thus, the 8080 chip *pushes* the return address onto the stack during the execution of a call and *pops* it off the stack during a return. The actual memory area set aside for the stack is determined by the programmer through the use of an LXISP instruction, which loads the sixteen-bit starting address of the stack into the *stack pointer register* located within the 8080 chip. It is the programmer's responsibility to set up a stack pointer before calls and returns are used; the programmer must also make certain that the stack area will not be used for other purposes during program execution.

In the program example shown in Table 1, we decided that the stack should have a starting address of 003 377. The first step in the main program, therefore, is to set the stack pointer to this address using the LXISP instruction. Later, when a call instruction is executed, the 8080 chip transfers the return address to the stack area of R/W memory. If the stack pointer is initially set at address X, the return address is stored with the low address byte in location X-2 and the high address byte in location X-1. Thus, *the stack adds address data at addresses below the address value of the stack pointer.* When the return address is popped back into the 8080 chip, the stack pointer is automatically incremented back to address X as the return is retrieved byte by byte. When the next subroutine is called, the stack locations are used for storage of the new return address, since the old return address has already been popped back into the 8080.

Subroutines may be placed one within another, or *nested.*

CB to 10

—part XVIII: several PLL rigs

Who called it "Ancient Mode?"

Recently, many hams have been converting CB radios to operation on the 10 meter ham band. With 40-channel CBs being sold now, there are many good used 23-channel units available at very reasonable prices. Some of these units will make very handy 10 meter AM phone transceivers, as they contain excellent AM receiver sections as well as efficient 4-Watt output transmitter sections in a small package ideal for mobile use. One of these units which may be easily (a few hours of work at most) and cheaply (less than $10 for the conversion and perhaps $40 to $50 for the radio) put on ten meters is the Midland model 13-882 C.

Although this article is concerned primarily with the 13-882C, the information can be applied to the following radios which use the PLL-02A phase-locked-loop IC in the same circuit configuration:

General Motors—CBD-10;
Hy-Gain—2680, 2681, 2683;
Kraco—KCB-2310B, -2320B, -2330B;
Lafayette—HB-650, -750, -950, Micro-223A
Lafayette—Com-phone 23A, Telsat 1050;

There are probably more units containing the PLL-02A in the arrangement discussed here. They can be recognized by the numbers PLL-02A on the chip near the front of the rig, three crystals in the radio, and the numbers PTBMO33AOX, PTBMO-36AOX, PTBMO37AOX, or PTBMO39AOX on the circuit board. There are some 40-channel radios using the PLL-02A in a different arrangement (only two crystals) which cannot be put on 10 meters by the method described here, as the crystal that has been eliminated is the crystal to be changed in this modification. Also, it should be noted that earlier versions of the units listed above do not use the same circuitry. The Kraco KCB-2330, for example, uses a crystal synthesizer, and the KCB-2330A uses a PLL-01A chip, which is not equivalent to the PLL-02A chip.

Photo A. An overall shot of the rig with the case off.

Operation of the PLL-02A

The voltage-controlled oscillator (vco), whose frequency is controlled by the PLL-02A chip and associated circuitry, provides injection to the first receiver mixer and to a transmitter mixer stage. The oscillator operates at 10.695 MHz above the

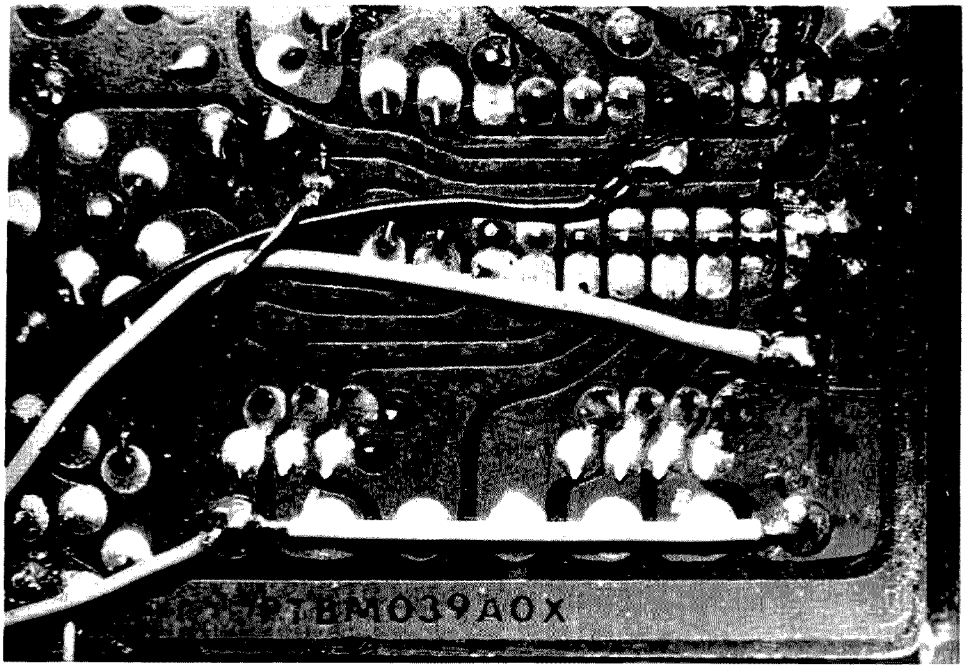

Photo B. Close-up of the channel-switch area of the circuit board, showing the modification to provide 23 additional channels 320 kHz above the "normal" 23 channels.

operating frequency, or 37.660 to 37.950 MHz for operation on CB channels 1 to 23.

Output from the vco is also mixed with the third harmonic of the 11.80666 MHz crystal oscillator (Q105) at 35.420 MHz, to produce a difference frequency of 2.24 to 2.53 MHz, which is fed into pin 2 of the PLL chip. 10.240 MHz energy from the 10.240 MHz reference/second receiver mixer injection oscillator is fed into the IC at pin 3.

Inside the IC, the 10.240 MHz signal is divided by 1024 to produce a 10.00 kHz reference signal. The 2.24 to 2.53 MHz signal is divided by n, where n is a number determined by the binary coding from the channel switch to pins 7-15 of the IC. See Table 1.

For channel 1, n is 224, dividing the difference frequency at pin 2 by 224. This frequency is compared to that of the 10.00 kHz reference signal. If the output of the n divider is less than 10.00 kHz, the voltage at pin 5 of the PLL chip (the control voltage for the vco) is raised, causing the frequency of the vco to increase. If, on the other hand, the frequency of the n divider output is higher than 10.00 kHz, indicating that the vco is too high in frequency, the voltage at pin 5 drops, lowering the vco's frequency. This action, similar to that of a thermostat, regulates the frequency of the vco. By changing the value of n (the job of the channel switch) or the frequency of the 11.80666 MHz oscillator and adjusting the slug in the vco oscillator coil (to set its tuning range), the operating frequency of the vco, and thereby the operating frequency of the entire rig, can be changed, while maintaining stability approaching that of a crystal oscillator.

Conversion to 10 Meters

To convert the radio to 10 meters, the 11.80666 MHz oscillator must be changed. The frequency required to give channel 1 a frequency of "F" MHz is:

crystal frequency (MHz) = (F + 8.455)/3

or 12.405 MHz for channel 1 at 28.760 MHz, the channel 1 for many converted CBs now in use, especially in the Los Angeles, California, area. The crystal should be available from any of the major crystal manufacturers. When ordering, specify the frequency desired and the model of radio you are converting. The crystal manufacturers usually have information on holder type, load capacity, and other specifications for CB units on file. If not, send a copy of the oscillator schematic along with the order.

To get the rig up to ten meters, the vco must be moved to near 39 MHz and the transmitter must be completely realigned. The easiest way I have found to do this is to use a dummy load, wattmeter, or other output indicator, frequency counter, or receiver covering 27 to 29.5 MHz with some accuracy and a signal generator or steady on-the-air signal in the following procedure.

With the unit off, isolate pins 5 and 6 of the PLL from the circuit board foil (use solder wick to remove the solder). Pin 6 is a protection voltage which drops to 0 if the PLL fails to lock up (i.e., the PLL can't regulate the vco frequency for some reason) and disables the transmitter. Pin 5 is the control voltage to the vco. Temporarily connect a jumper wire from pin 1 (5-volt supply to the IC) to the foil at pins 5 and 6, without connecting to the pins themselves. It probably wouldn't hurt the IC if the pins did touch, but, at $12.00 or more for a replacement IC, I don't recommend taking chances. This temporary modification runs the vco at maximum frequency, unlocked from the PLL, and overrides the transmitter disable line, allowing the transmitter to function. Connect the wattmeter and dummy load to the transmitter. Connect the frequency counter according to its instructions to monitor transmitted frequency.

Turn the unit on and key the transmitter. The frequency counter should read somewhere above 27.4 MHz. Tune the slugs of T111, L103, L104, T102, T103, L106, L109, and L110 for maximum output (the numbers are next to the coils on the circuit board). Exercise extreme caution in tuning, as the slugs are very fragile. Tune the vco oscillator coil, T101, until the frequency is about 300 kHz higher and retune the above coils for maximum

Binary number:			256	128	64	32	16	8	4	2	1

A 1 indicates 5 volts at pin; 0 indicates no voltage.

Table 1.

output. Repeat the procedure, "walking" the transmitter up to about 200 kHz above your highest ten meter channel (about 29.35 MHz for channel 1 at 28.760 MHz). Turn the unit off.

Disconnect the 5-volt jumper wire which was temporarily installed from pins 5 and 6 to pin 1 and reconnect the pins to the foil. Turn the unit back on, and set the channel switch to channel 1. Adjust the trimmer capacitor next to the crystal for the proper output frequency. Turn the channel switch to channel 18. Adjust all of the coils mentioned except T101, the vco coil, for maximum power output. (This is done at a higher-than-center frequency because the power output drops off faster above the peak frequency than below. This is normal even on 11 meters and should not be the cause of any worries about changing capacitor values, trimming coils, etc., unless the coils just refuse to resonate. All three units I have converted have tuned beautifully with 4 to 5 Watts output without juggling any component values.)

Connect the transceiver to the signal generator or other signal source. Set the channel switch to channel 12 and adjust the generator for output on the same frequency. Adjust the rf stages in the receiver (T104 and L112) for maximum received signal strength on the S-meter. Alignment of the other receiver tuning adjustments should not be necessary, as the i-fs are on the same frequency as when the unit worked a couple of MHz lower.

Additional Channels

Channel 27 may be available in the blank position between channel 23 and channel 1 on the dial by installing an insulated jumper wire on the foil side of the circuit board between the terminal on the far left of the channel switch and the terminal on the far right of the switch. This modification will supply 5 volts to the vco and to IC pins 8 through 10 when the channel switch is in the blank position. Channel 27 will be 20 kHz above channel 23, or 29.070 MHz for channel 1 on 28.760 MHz. On some units, the blank will be another channel 1, but it's worth a try and, if it doesn't work on your rig, you can always take the jumper back out.

Each channel can be moved up or down 320 kHz by performing one of the following modifications. If one of these modifications is done, each channel will have two possible frequencies, one 320 kHz above the other. Thus, channel 1 in the higher position will be 30 kHz above the lower channel 23 and 10 kHz above the lower channel 27. In other words, the 320 kHz offset switch is selecting between two different bands of 23 channels (or 24 channels) each. The only component required for the modification is an SPDT switch, which may be installed in the front panel, or, to preserve the stock appearance of the radio, the function of an existing switch may be changed.

To be able to move the 23-channel band down 320 kHz, isolate pin 10 of the IC by cutting the foil on the circuit board around it. Then wire the switch as shown in Fig. 1.

To move up 320 kHz requires a little more work and is the modification I have shown in the photographs. Cut the foil on both sides of the connection to pin 7 to isolate it from ground. Then cut the foil to isolate pins 8, 9, and 10 as a group from the switch contact and from the thin strip of foil going to one end of R103, the series resistor in the B-plus lead to the vco. Install a jumper from this end of R103 to the 5-volt line at the left-most terminal of the channel switch or to the point shown in the photograph, which is just on the other side of a jumper from the terminal. If this jumper is forgotten, the vco won't oscillate. Connect the switch as shown in Fig. 2.

After the conversion has been completed, affix a label to it in an obvious place stating that the radio is not capable of operation on Citizens Band frequencies and that an amateur radio license is required to use it. The label could save a lot of embarrassment or a pink ticket from the FCC in the event a passenger riding in your car says something like "You have a CB just like mine!", picks up the microphone, and yells "Breaker 4" all over the world on 29.050 MHz.

My 13-882C on ten meters has provided quite a few contacts, mostly with stations on the west coast. My dad (Dale K9HIS) also has a 13-882C on ten, and my brother (Larry WB9BAQ) runs a 13-857B (an 882C without the noise blanker or antenna warning light) mobile with a trimmed-down CB magnet-mount antenna, working mostly stations on the west coast and southeastern U.S. What 4 or 5 Watts of AM phone will do on a clear frequency gave me quite a surprise. Who called it Ancient Mode, anyway? ■

PROM IDer for Longer Callsigns

—don't be caught short

Take care of RPT.

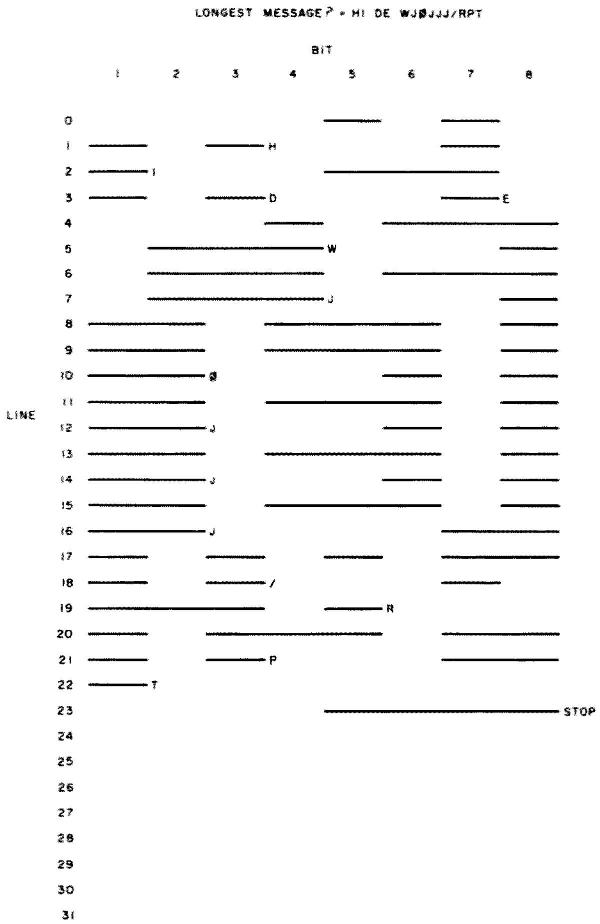

Fig. 1. A "not-so-typical" callsign.

E. E. Buffington W4VGZ
2736 Woodbury Drive
Burlington NC 27215

The Peter Stark K2OAW CW identifier has seen good service for several years now. Since it was inexpensive and easy to program, I adapted it to a plug-in configuration. (See *73 Magazine*, June, 1977.) Now it seems that a CW identifier with longer message capability is needed, due to the demise of

WR repeater calls. Now we must identify the repeater with the trustee's callsign followed by RPT.

The longest of callsigns can be programmed by altering the bit pattern of the 82S23 memory. Fig. 1 lists a not-so-typical callsign to show how much room is available on the ROM.

You can do it right the first time if you remember a few rules and definitions. First, a slot is the minimum length of time between data transmissions. Now then, a dit is 1 slot high followed by 1 slot low; a dah would be 3 slots high and 1 slot low. The space between characters is 2 slots low. You should leave a few slots at the beginning to allow the transmitter to come fully on. A stop command consists of bits 5, 6, 7, and 8, all high.

The leading edge of the start pulse causes the IC1 flip-flop to change state, resulting in the hold command going high. The $\overline{Q}$ output of the flip-flop enables the two 7493 four-bit ripple counters and the 74151 parallel-to-serial converter. The 8 bits of each line of memory are thus pulsed out until bits 5, 6, 7, and 8, being high, are detected as a stop command. It should be pointed out that no other data should be on the stop line as it would never be pulsed out. A keyed CW oscillator that furnishes audio to the transmitter completes the circuit.

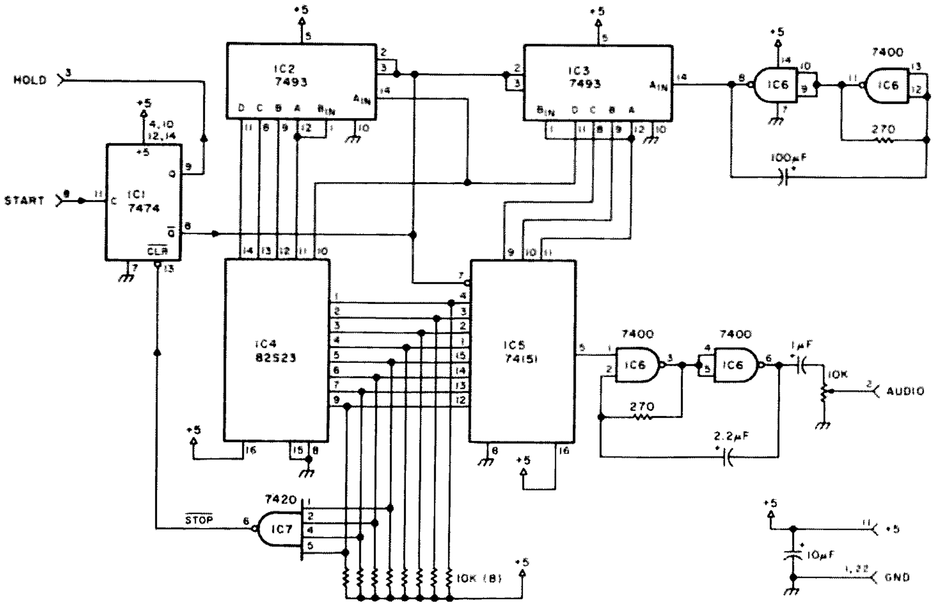

Fig. 2. PROM CW identifier.

This ID unit plugs into the same socket (with no wiring changes) as the one shown in my June article. A logic-high pulse starts it, and during the time that the ID unit is running the hold command is high to keep the transmitter on.

A sample program is shown in Fig. 1. As you can see, this "longest call" uses only lines 0 to 23. There may be room to have even your QTH included.

Contest freaks can have several ROMS programmed for their various contests, and just plug them in when contest time rolls around. I have one programmed: "DE W4VGZ Transmitter

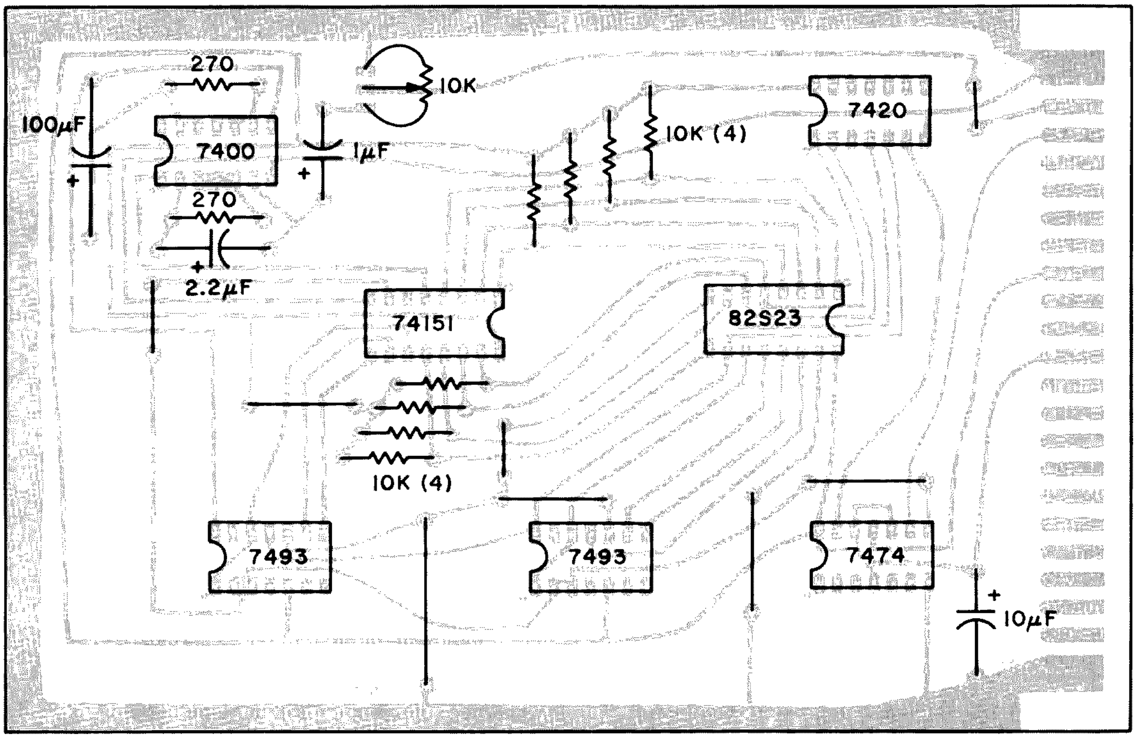

Fig. 3. Component layout.

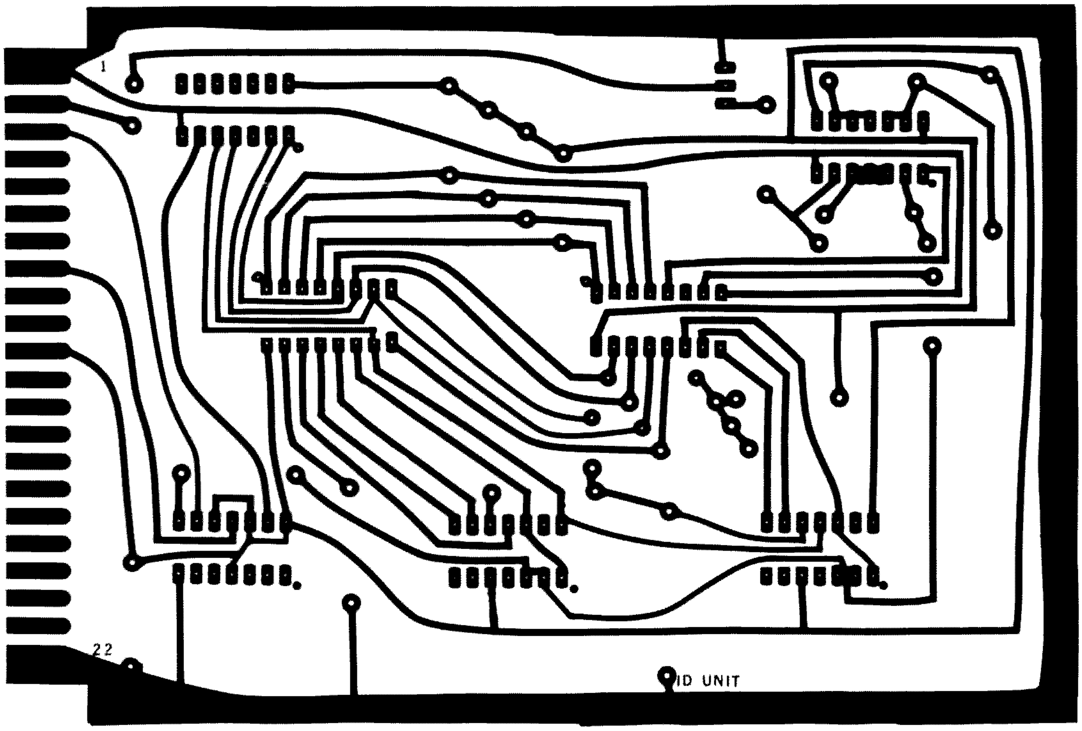

Fig. 4. PC board.

Hunt Hi Hi." I use a VHF Engineering 2 meter transmitter and a 555 timer to cycle the ID unit. With battery power, this unit can be hidden almost anywhere.

I will gladly correspond if you have any questions concerning this or any of the other articles I have written. Please send an SASE! ■

The W7GAQ Key Collection

— 250 museum masterpieces

Do you have one he doesn't?

It could be the Smithsonian Institute or it could be little Foothills Junior College in California which houses the Lee De Forest collection— John Elwood W7GAQ isn't sure which, but one of these museums, or perhaps some other one in the United States, will one day be privileged to display the finest collection of telegraph keys in the world. John is devoting his retirement years to acquiring and restoring with almost unbelievable care as many different keys as he can possibly find. One day when he deems the time right, he will donate the whole collection to the museum of his choice.

John Elwood W7GAQ holds a small English spy key that he swapped for with an English ham. Three and one-half inch screwdriver shows the relative size of the tiny key.

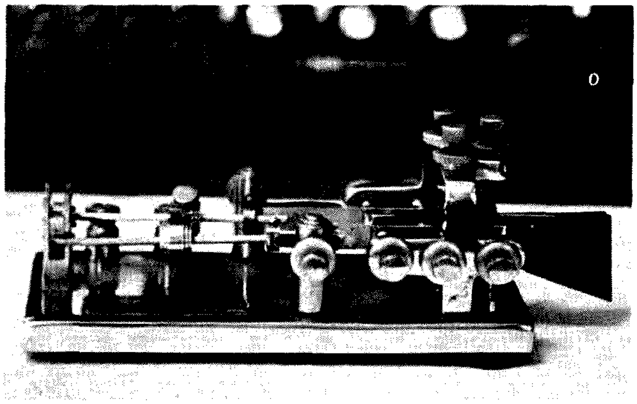
At the moment, John's collection amounts to 250 different types of keys, which he is quick to point out is not the largest collection in the world. But to this writer, who grew up in the atmosphere of the tool-and die-making trade, it is obvious that there may be no one else on Earth willing and able to spend as much as fifty hours cleaning, restoring, and polishing a key the size of a J-38, and more on a complex key such as an original Martin Blue Racer. John Elwood's keys look more like a modern elaborate sales display than an antique collection. He has been that deliberate and final in his restoration and care of them.

John was introduced to CW radio at the Army Air Force Radio School in Sioux Falls SD, in 1942, but it was several years before he got a chance to pound brass. He and his twin brother, Henry E. III, worked together running a control net system, VHF direction-finding station at Paine Field, Everett WA, in 1943. Then John went overseas with the 328th Fighter Control Squadron, 64th Fighter Wing, and for the duration of World War II he ran direction-finding equipment helping to get triangular fixes on disoriented fighter aircraft and vectoring them in to safe landings in Italy, Corsica, France, and Germany.

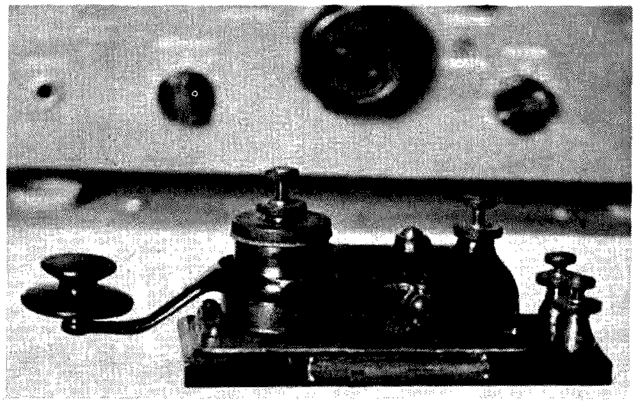
John finally got a chance to work CW as an operator in Panama, but he had to sign up for another hitch in the Air Force to do it.

"We were sent out to a place called Rey Island to work in an administrative net handling CW traffic back to Panama," John said. "It was great, and I knew I was hooked on CW for the rest of my life."

John worked CW in Greenville SC, and then got his best shot at concentrated CW operating in Operation Seminole, a joint Armed Forces field operation in Florida in 1947-48. Then he was shipped to England to operate CW at Burtonwood in the Midlands. All this time, the little contact machines that made CW communication



Melehan Valiant, made in the 1950s. This is a favorite key of John's, because you can set the vibrating arms for both dits and dahs, the dahs being three times as long as the dits. Then both dits and dahs are made by spring action.



This is a 1912 Flame Proof hand key manufactured by Machinery Division, Boston Navy Yard. The key is rated at 1-2 kilowatts. It is cast iron with brass hardware.

possible were facilitators to John. The charm of the little devices hadn't yet struck him.

The Berlin Airlift of 1949 taxed all parts of an airplane to the breaking point, radio equipment included. John was flung into a maintenance gap and had to foresake CW for a while.

"I worked my butt off repairing radio equipment on C-54s during part of the airlift," John said, "but as soon as I could, I switched back to operating CW and finished out the Berlin Airlift doing ground-to-air communication with weather ships over the North Sea."

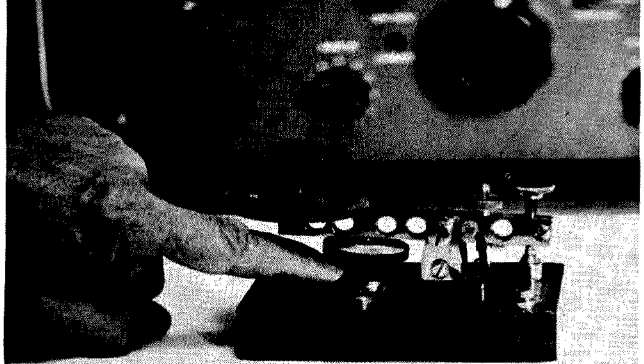
John wrapped up his Air Force career as ROTC radio instructor at Ohio University. Then he switched to the Federal Aviation Agency, from which he retired when he was Facility Coordinating Officer at the Los Angeles Air Route Traffic Control Center at Palmdale CA.

It was at this final duty in California for Uncle Sam that John finally got swept away by the charm of telegraph keys—and it took a woman to gather him up. Louise Moreau, now W3WRE, was living in California in 1971 and working CW with her WB6BBO call. Since she was a prime collector of telegraph keys, she responded to a call from the Lancaster Radio Club to speak about them. John sat in the audience and listened and found himself captivated by the love and enthusiasm that Louise expressed for her keys.

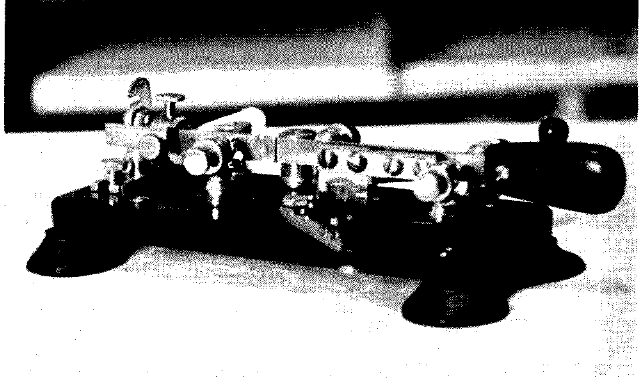
"She spoke with such excitement and interest," John said, "that I couldn't help wanting to become a key collector. When I left the room that night, I was a collector."

A friend gave John a big Japanese key and, as a gesture of fellowship, John cleaned it up in one of his now-routine fifty-hour restoration projects, drove down to Altadena, and presented it to Louise Moreau. Louise showed him her key collection representing twenty years of effort and encouraged him to get on with his own collecting. This he did, and he and Louise have been friends and correspondents ever since.

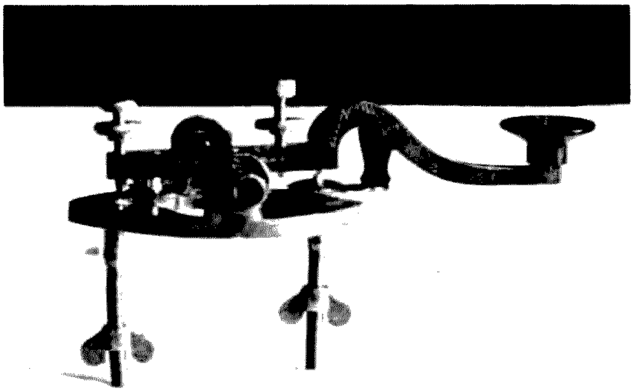
John's wife Edie bought him the first key for his own collection: a Boston Fire Alarm key which she got from J.J. Glass Surplus Radio in Los Angeles. John went to work on the key, soaking and scrubbing and polishing until every speck of foreign material had been removed. That key amounted to free rein for John. He hit the highway at every chance, scouring the whole of the west coast for telegraph keys. Edie caught the travel bug, too, and went on nearly every trip



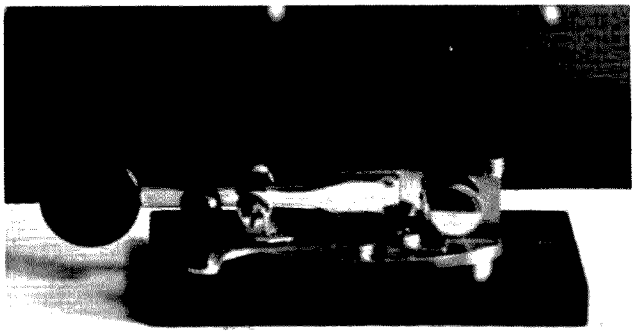
John Elwood's well-used keying finger points to oil well on the Ducrete and Roger (Paris) oil break key. Oil dampened the spark of spark gap transmitters. The key was a gift from Ed Rasner W2ZI, Trenton NJ. The gear in the background is John's R-391 Collins receiver.



This is a Signal Electric semi-automatic key that can be used as a sideswiper by dropping a locking arm over the vibrating arm and closing the arms of the contact terminals.



This G.M. Phelps "camelback" leg key is from the 1850-1860 era. The inventor, George M. Phelps, was the chief of Western Union at Utica NY. It was he who introduced the spring adjustment for this type key. Brass "legs" were inserted through holes in top of desk and the key was tightened down with brass wing nuts.



Here is a J.H. Bunnell & Co. "Sideswiper" double-speed key. It requires only half the movement of an ordinary key. Advertisements claimed it eliminated muscle cramping. John turned down $200 offered for this key when it was on display at the ARRL Convention in Hollywood. In the background is an RM18 US Signal Corps Type 5007A British Air Ministry control unit, part of the SCR-575 VHF/DF unit of the type John used in World War II.

with him.

"If you see any kind of antique store, junk shop, or radio store between Oceanside CA and Vancouver Island, Canada, that looks like it might have a telegraph key in it, we've been there," John said. "And we've dug up a lot of keys worth saving."

It wasn't long before John's friends heard about his key collecting and, respecting his zeal and purpose, they kept their eyes open for keys. About twenty of them have had the satisfaction of contributing to his collection.

Once, in Portland OR, John and Edie went into a little, out-of-the-way antique shop, and what they found made their trip a success. The proprietor told them he didn't know what he had, so they should go into the back room and take a look.

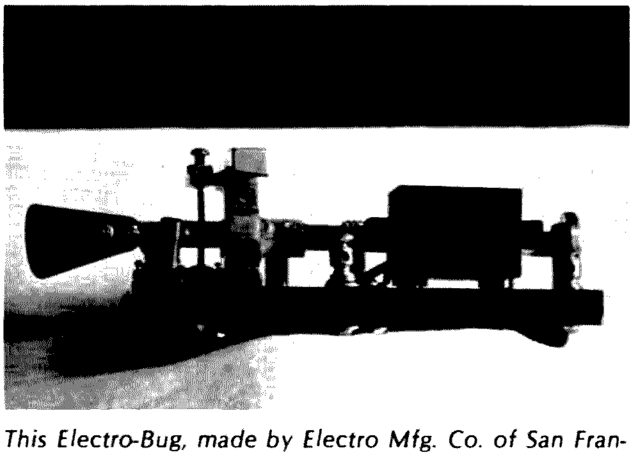
"We looked," said John, "and found big boxes with an antique radio station in them, cat's whiskers and all. But since I don't collect radios, we picked out two camelback keys and a Marconi wireless antenna knife switch built by Cross and Hines, and we bought them and left."

John wrote a friend in California about the old radio station, and the friend went up to Portland and bought it. He got an extremely rare Marconi loose coupler, a Clapp-Eastham one-half-kW spark transmitter and receiver, a marble base detector, a Colby loose coupler, and some United Wireless gear.

Once, at the Rose Bowl flea market in Pasadena, Edie, who John swears is clairvoyant regarding radio gear, had a strong feeling that this would be John's day. She was right. John found a man with a wooden box of telegraph gear for sale for fifteen dollars. Among the contents were a Martin Vibroplex, a Boy Scout training key, three Menominee leg keys, a Bunnell straight key, and four Bunnell sounders. John paid the man the fifteen dollars and picked up the box to leave.

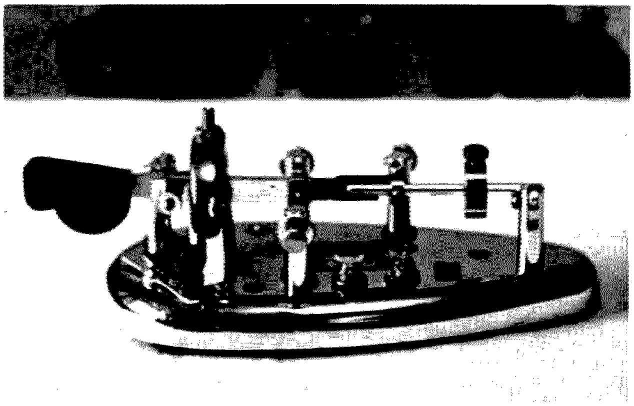
"Hey," said the man, "don't take that box. It doesn't go with that other stuff."

As collecting became more difficult, John began advertising in the maga-

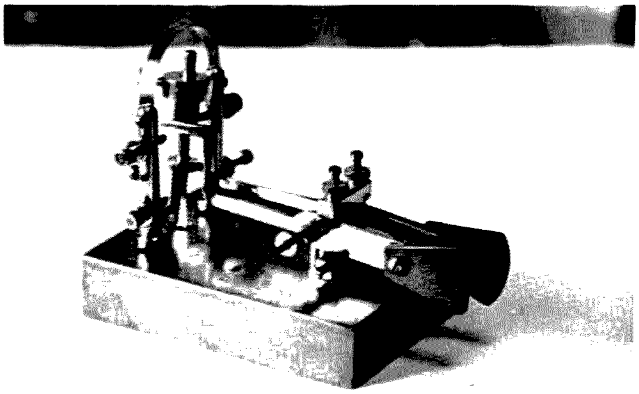


This Electro-Bug, made by Electro Mfg. Co. of San Francisco, has a line magnet and works like a doorbell buzzer, attracting the vibrating arm and then breaking the contact. "You can hold the paddle over and it will make dits all day long," says W7GAQ.

This Horace G. Martin Rotoplex key built for the US Army Signal Corps during World War II has a black crackle finish on a steel base and is mounted on a quarter-inch rubber mat.



This chrome-steel teardrop base semi-automatic key was made by T.R. "Ted" McElroy in Boston. McElroy is credited with the Morse code receiving speed record of 75.2 wpm set in a tournament at Asheville NC on July 2, 1939.

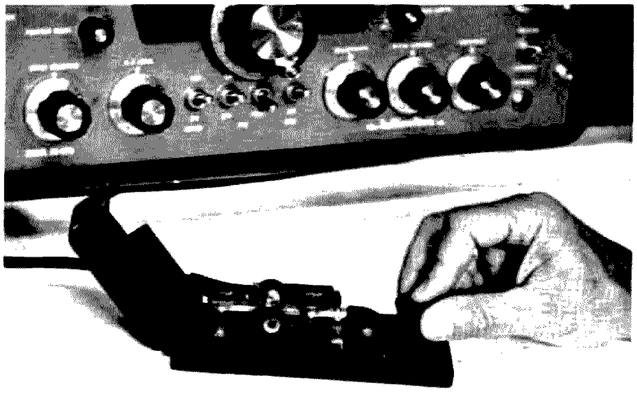


This is an Australian PMG vertical semi-automatic landline key made for the Postmaster General Department. The PMG controls all communications in Australia.

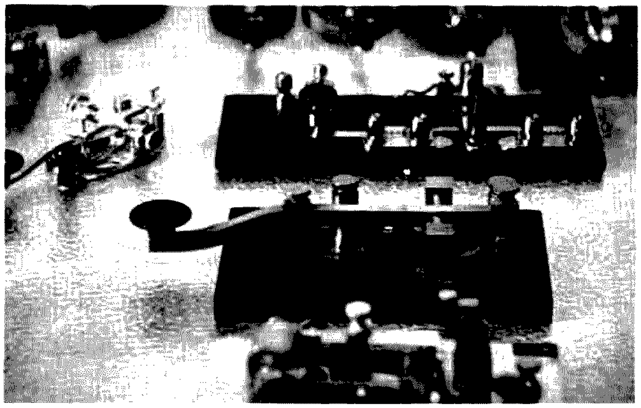
zines of England and America. Half the world reads English and American magazines. John found that the foreign countries have collectors, too, and they were interested in swapping keys. Since John had duplicates of some types, he made mail-order agreements with several hams and, as a result, he got some interesting German, French, and English keys. Recently he has made contact with a doctor in Belgium who collects keys, and they have worked out a mutually worthwhile swap agreement. One ham in Australia has traded nine keys to John.

When John gets a key that is in rough condition, he applies penetrating oil to frozen or rusted screws, nuts, and moveable parts. Once the parts have loosened, he disassembles the key completely and submerges all metal parts in carburetor cleaner to remove dirt and lacquer and get down to base metal. Then he makes a cleaning potion of one-third cup each of baking soda, white vinegar, and ammonia, and one cup of very hot water. He soaks all brass parts in this solution for twenty-five minutes, polishes them with Dupont chrome polish, washes them with soap and water, and dries them. Then he finishes up the brass with Happich Simichrome polish (German) and washes it with hot soap and water. On the steel parts, he uses steel wool, working down to four-ought grade. He uses taps and dies to restore threaded holes and screw threads. He has chrome- or copper-plated parts re-chromed or re-coppered. If a part is missing, he hunts for it until he finds it. Then he reassembles the key and puts it into his display case. Because of the time-consuming job of keeping brass keys polished, John is now thinking of coating them with lacquer.

John has an almost clinical attitude toward his keys—his patients. There they are in all their sparkling beauty. He has taken them in, analyzed their difficulties, repaired them, and stitched them back up again as good as when



Here is a German Baumuster T1 military key of the 1930s. "This is my favorite hand key because the adjustments are precise and the concave knob gives it a good feel," says John Elwood, who purchased the key from Louise Moreau W3WRE. In the background is John's Hallicrafters SX-101A receiver. That's John's precise fist in action.



The thick-base key in the foreground is the famous "Boston" key made by Class-Eastham Co. This key is called a "Cadillac Class" key of the spark era by Louise Moreau. The key was designed for luxury liners and the yacht trade, and every amateur wanted one. Behind it is a Boston Fire Alarm key, and to the left is a recent copy of the T.R. McElroy Professional Hand Model Key made by Daniel L. McElroy, grandson of the record holder, who is making them in honor of his grandfather. Out of focus in the foreground is a Mecograph semiautomatic key once headed for the Smithsonian until its owner, Howard Lorenzen W3BLC, heard of John Elwood.

they were created. Now it's time to think of them as healed. They are well again, and that's a fact. Now he must get on with the business of locating and repairing others. He feels he must be successful before collectors with only a monetary interest in keys have collected them and taken them out of range of the ham fraternity.

John wishes he could swap keys with more hams in this country and abroad. He'd especially like to get the miniature Bunnell key and sounder once used as watch charms. He'd also like to get a Vibroplex vertical bug. He never sells keys, though he has been offered as much as two hundred dollars for a small sideswiper key, but he will be happy to trade and will work out satisfactory trade agreements.

Not once did John speak of "my" collection. He seems rather to consider the keys as the property of everyone. His responsibility seems to him to be an almost sacred duty to get the keys and make them new again so that the world will be able to see them and know what pounded out man's joys, sorrows, successes, and failures during a century and a half of incredible progress in communication.

Also, John is preoccupied with that ultimate decision he will one day have to make: Which museum will display the keys to the best advantage and take the best care of them?

Whichever one he picks, that museum will some day find itself the keeper of a remarkable and interesting collection. ■

Proper FM Transceiver Adjustment

—good club project

In search of the crisp signal.

Anyone who listens to the great number of rigs on two or six meter FM these days may wonder why there is such a great variation in the quality of signals they hear. One HW-2036 may sound clear and crisp, while the next may sound distorted, especially on audio peaks.

In almost 100% of the cases, the problem can be traced to either over-deviation or off-frequency operation, and sometimes a combination of both. Unfortunately, most hams are quick to notice low audio, but few seem to point out excessive audio.

If you have been active on SSB or AM, you may ask why these two items are so important to maximum range when using the FM mode. If you take a moment and glance at Fig. 1, we will try to show you.

Fig. 1 shows an FM transmitter on 146.520 MHz with a 1000-Hz audio tone deviating the carrier frequency ±4.5 kHz, and being received by a receiver with an i-f passband of ±5 kHz. (Please note that an i-f filter selectivity curve is not as sharp as depicted.) As one can see, the on-frequency signal, with its 4.5 kHz of deviation, fits perfectly through our i-f filter where it enters the FM detector and becomes a good clean signal at the speaker.

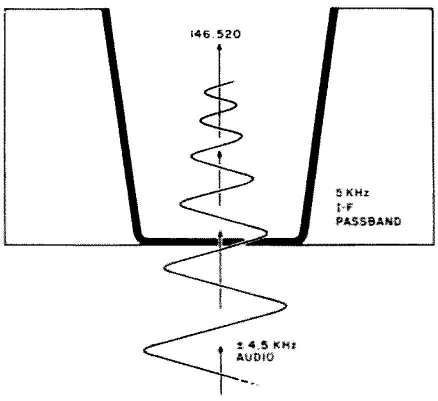

Fig .1.

Now let's move the transmitter off frequency by 3 kHz and see what happens. This may not seem like any amount of error to be concerned about, but look at Fig. 2.

Since the receiver discriminator, or some form of FM detector, only converts to audio what passes through the i-f filter doorway, one can rapidly see why a good signal can sound distorted when it's only 3 kHz off frequency. As Fig. 2 shows, over 60% of the transmitted audio on the high side is being chopped by the filter and over 60% of the low-side audio is attempting to be detected on the high side of the carrier frequency. As a result, audio distortion occurs.

You may ask why a weak off-frequency signal is more noticeable than a strong local signal. The true selectivity curve of the i-f is such that strong signals brute-force their way through the filter, thus not affecting the audio quality as much. The selectivity of the receiver is directly proportional to the strength of the signal being received. This does not mean that if you are close to the repeater your frequency is not as critical. Remember, your off-frequency signal could be affecting the user of the next channel up or down.

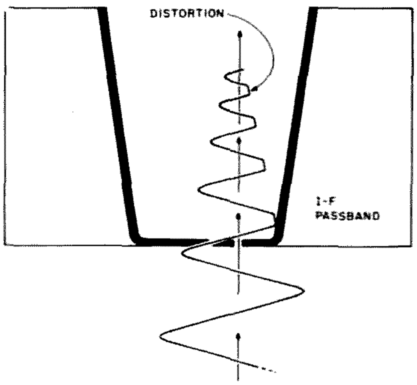

Fig. 2.

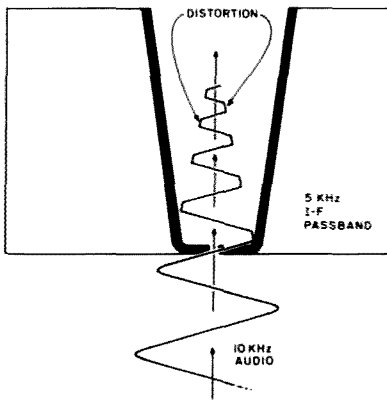

Fig. 3.

The only solution to the above is to adjust your transmitter back on frequency, or reduce your deviation 60% by backing away from the mike. The latter is only a poor temporary cure.

Deviation

Since the receiver i-f passband can accept only those signals that transmit within its 5-kHz limits, we must make sure the transmitter does not exceed this amount.

If you look at Fig. 3, it is very apparent why over-deviation (±10 kHz) will produce highly distorted audio.

At a recent tune-up session at the Kitchener-Waterloo Amateur Radio Club, some rigs were found to be deviating in excess of 15 kHz. If you visualize this amount of audio trying to find its way through a 5-kHz filter, it is no wonder why some signals were almost unreadable prior to the tune-up clinic.

With the number of repeater frequencies already used in the Metro areas, the repeater councils have adopted a plan to split the channels and create new ones every 15 kHz, thus placing a new repeater pair between each existing one. Because of this split, it is rapidly becoming very important that our deviation be kept at 5 kHz maximum.

Fig. 4 shows what happens when an over-deviating signal is placed on the air adjacent to one of the new channels.

This same adjacent channel interference can occur if the transmitter is off frequency, since it allows part of the signal to fall into the passband of the receiver using the next channel up or down.

The new band plan adopted for use with these new split or "tertiary" frequencies will minimize some operator error in the following way. All *new* frequencies *above* 147.000 will use low inputs and high outputs (reverse of the standard high in, low out). This will mean that off frequency and over deviation on a repeater input will not bother the adjacent input, only the output, so you will only get pins in your coax from your neighbors, not the complete repeater group. This will put all repeater operators in a position where they will be forced into keeping the peak deviation below 5 kHz and off-frequency operation to less than 1 kHz. If they wish to meet current DOC (Department of Communications, our FCC) commercial specs, they should keep within 5 ppm or 735 Hz at 147 MHz.

Don't feel you will have to run out and buy a new super-selective rig with these new splits. They will be issued about 50 miles away from adjacent channel repeaters and should not cause a problem except on the older wideband rigs. Current DOC guidelines are 35 miles between tertiary frequencies, with some as close as 5 miles with no interference problems, so don't get upset about the new splits.

Frequency Adjustment

The best method for frequency adjustment is, of course, with a counter capable of 150 MHz. A counter capable of only 10-15 MHz can also be used by reading the actual oscillator frequency and calculating the frequency by multiplying by the number of times the rig multiplies. For example, a GE Prog Line using a 6-MHz transmit crystal would have an oscillator frequency of 6.1050 MHz when producing a 146.520 output.

If no counter blesses your ham shack, have a local ham lend you his receiver that is known to be on frequency and uses a discriminator for FM detection. This type of detector, when properly aligned, produces a voltage relative to "0", either positively or negatively proportional to the amount of off-frequency operation. You simply adjust your transmitter trimmer until the discriminator reads zero on the meter. A lot of the new rigs use ratio detectors, or quadrature detectors, which cannot be used to determine receive frequency unless it is beat against an accurate i-f frequency generator, e.g., 10.7 MHz.

Another method to use if no counter and no receivers with discriminators are available is to transmit a very weak signal to a known on-frequency receiver. Simply adjust your trimmer while talking into the mike. The point where your audio has the least distortion should be very close to frequency.

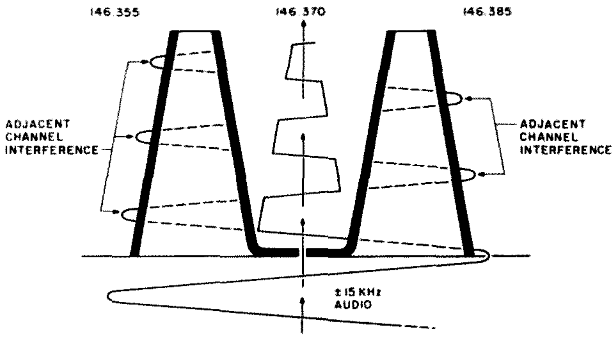

Fig. 4.

Deviation

Deviation is normally set by the factory before shipping. Unfortunately, 90% of the rigs that get on the market appear to be set at 7.5 kHz. Almost all users of these rigs sound much better when they back off from the microphone. As we all know, within a couple of transmissions, we tend to crawl back into our normal mike habits. The only solution is, of course, to adjust the deviation as set out in the manufacturer's instructions.

To set this control properly, one needs a calibrated deviation monitor which very few hams, including myself, own. The next best way is with a weak signal into an on-frequency receiver, adjusting the deviation for best audio. Have the person adjust his squelch at threshold with no signal. When you transmit, try whistling. If the squelch closes, you are exceeding the bandwidth of the receiver and should back off a bit until the squelch does not close on peaks. It is very important when using this method that the signal be just full quieting, .7-1 uV.

The commercially accepted level for adjusting FM deviation is 4.5 kHz of audio. This is measured with a 1000-Hz tone driving the transmitter audio limiter stage into limiting.

So, as you can see, one does not have to mortgage the house to invest in test equipment in order to have a good-sounding signal on 2 meters. Most of these adjustments, if set once, require very little attention. Because of this, there are many generous hams who have the equipment and don't mind helping out a ham in trouble. ■

Dual-Band Smokey Detector

—Super Scooper does it all

The battle goes on.

The "Smokey Detector," described in the 1976 Holiday issue of *73*, has been the subject of much mail received at W1SNN. Many have asked if it could be used on the higher frequencies found with newer types of radars which have been designed to improve entrapment techniques and decrease confidence in Smokey Detectors.

The author has learned of new methods used to deploy obsolete police radar along highway ranges used for surveillance. Newer radar is used in conjunction with this method, which is known in police circles as "seeding." The older radar units are set up and left unattended so that they "illuminate" stretches of highway for many miles—depending on the number of "seeds" that are used. Most of those units operate on 10.525 GHz in X-band.

The newer radars, usually operated from a fixed position, are hand-held and triggered only when the device is pointed at a particular stream of traffic. The purpose of seeding is to keep the Smokey Detectors activated and, therefore, cause drivers to slow down. Confidence is soon decreased in the Smokey Detector, however, and the unsuspecting driver is trapped by the hand-held device. Yes, it works on X-band, too, but too late for a detector warning because the speeder has moved right into trigger range.

But that isn't the only technique used. How about this one: As before, seeding is used. Radar which has been designed to be used in vehicles while moving is employed. These units have a device that arithmetically removes the vehicle speed, allowing the officer to pursue and record the speed of the car being chased. Here again, the police car can depend upon the seeds to keep Smokey Detectors operating, and even when the police come into range of vehicles using detectors, they can follow without detection. The new radar operates in the K-band region. Most of the older radar detectors will not receive at this frequency range; again, confidence is lost.

These techniques are used by large municipalities and state agencies for the most part. They can afford to maintain the antiquated equipment for seeds. Others will be adopting them, however, because of newer seed equipment that is being manufactured by several companies at prices which can fit smaller budgets. The newer units are simply a small oscillator and battery supply. The oscillator will feed an antenna that floods an area with the oscillator's signal. They can be left unattended, fastened to street signs and stop-go signals. Other radar units that promise greater control for police agencies are in the works; the war is still on.

What can we do with our radar detectors? Well, we can update them to detect the newer frequencies and learn how to use the older ones to be sure that we are detecting an active radar and not a seed. It is not too hard to manufacture detectors that are sensitive enough to detect a seeding and radar entrapment, and thus provide a warning that both are being used, or to warn that just a higher-frequency moving radar is activated. Look at the block diagram of a dual warning system which accompanies this article.

A circularly-polarized horn coupled to a circular waveguide is coupled to a pair of crystal detectors. The detectors are mounted in cavities which support the frequencies of interest. The larger of the two cavities is tuned for the X-band frequency, 10.525 GHz, while the smaller one has a step ridge mounted into its E-plane coordinate. The step ridge performs as a tuning device that allows the smaller of the two cavities to work over the 16.5- to 26.5-GHz range. There are several frequen-

cies used in this range for hand-held and moving-surveillance radar units.

Coupling to the circular waveguide is accomplished by careful placement of the two detectors which are mounted in rectangular waveguide to provide coupling to the circular mode.

Two preamplifiers, one for each waveguide-mounted detector, amplify the signal—which is the dc component of the detected signal. The amplified signal is passed through a CMOS switch which serves as a signal modulator.

Each of the switches has its own driving oscillator. An oscillator at 1 kHz modulates the X-band-detected signal, and another at 400 Hz serves as the K-band signal modulator.

The outputs of the two modulators are summed at the input of an audio amplifier that drives a loudspeaker.

The resulting warning signal will be two-toned when both X- and K-band radar units are detected. If just the X-band detector is activated, the higher-pitched tone of the 1-kHz oscillator will be heard. Likewise, the 400-Hz signal will be heard when a K-band signal is detected. When both are on, it is very likely that you are in an entrapment area which is well seeded. Beware when the higher-pitched tone stays on for long periods. If it is on for over 4,000 feet of driving, you are probably in a seeded area. If the signal continues, slow down and watch for your friend in blue.

The circuitry illustrated here is straightforward audio construction and can be built on a small board using flea clips or wire-wrap. No special attention is required. The completed board must be mounted so that the leads that connect to the detector outputs are short—that is, not over six inches long. Several adjustments to the electronics are required and will be described below.

The hardest part of the construction of the Super Scooper is its antenna and circular waveguide. In the original Smokey Detector article, instructions were given on how to construct the horn antenna. This was the subject of many inquiries both as to its beamwidth and gain and relative to variations from the given dimensions. First of all, the gain of the antenna is approximately 14 dB over a reference antenna that provided a 3-dB gain standard. The gain standard was determined in a laboratory using a section of circular guide terminated in a matching impedance to a standard signal generator. A similar antenna was used with a detector and spaced one meter from the generator gain standard and three meters above the ground. Once a level was determined by setting the signal generator attenuator to produce a full-scale deflection on the detector indicator, the new antenna used on the Super Scooper was substituted for the transmitting horn, and then the attenuator was readjusted to produce the same full-scale reading as with the reference antenna. The attenuator difference was 14 dB at 21 GHz and 17 dB at the X-band frequency.

Since most amateurs will not be able to duplicate these dimensions, a pattern shown in the drawings has been laid out so that it can be closely duplicated. Several antennas were constructed and measured, and variations from the values given were not worth mentioning. The dimensions were deformed

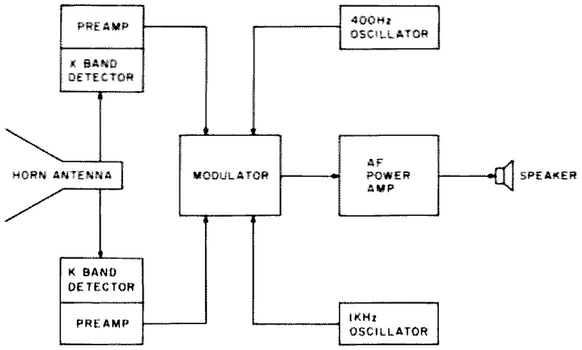

Fig. 1. Block diagram, Super Scooper Smokey Detector.

from true circular to a shape which occurs when the seam is soldered. Not a true circle, the variation in gain wasn't worth the trouble to measure. It is apparent that that would take quite a departure from a true funnel shape.

The beamwidth was measured, and it required a considerable amount of time to determine that it was a circular beam of 9 degrees. Variation from a true funnel shape does distort the beam considerably, so care in achieving the cone shape should be exercised. The beamwidth was measured on an antenna range at the same laboratory, using a quality of range equipment probably not available to most amateurs. A nine-degree beamwidth is very similar to that of most circular antennas used on police radars and should intercept most radiation from them.

To construct the antenna, it is necessary first to acquire a piece of copper flashing sold in most hardware stores. (Brass can be used but should be thin so that it is easily worked.) The sheet should be at least 10″ x 6″. With a compass, lay out a 9-5/16″ circle and, from the same center, scribe the second ½″ circle. (See the drawing.) Outside of the circle leave enough metal so that the tooth-like section can be cut and bent. Cut the sheet with tin shears and flatten out all bends and dents acquired in the cutting procedure. Make sure that the tooth-like cuts are bent at right angles to the sheet, and then lay it aside.

Next acquire a piece of construction paper with the same dimensions as the flashing sheet. Lay out the same dimensions as before, but forget the tooth-like part—just cut a smooth ½″ half-circle. Cut out the complete sheet so that it can be glued at the seam tab. Now you should have a cone that has a mouth 3¾″ in diameter and a length of 4-1/16″. The opening at the rear should be about ½″ in diameter.

Make up about two cups of plaster of paris that is nearly dry but easily molded, and fill the cone so that a substantial amount of it protrudes from the ½″ hole. Shape the plaster so that the cone is as rounded as possible, and set it aside to completely harden. This form will serve as a mandrel for the metal horn when soldering its seam. Simply bend the metal around the form and hold it in place with rings placed at several points on the cone. Solder the seam. Shape the metal and set it aside until the circular guide is finished.

The circular waveguide is made from a section of ½″ water pipe 3″ long. Lay out the dimensions shown in the drawing. Measure up along the outside

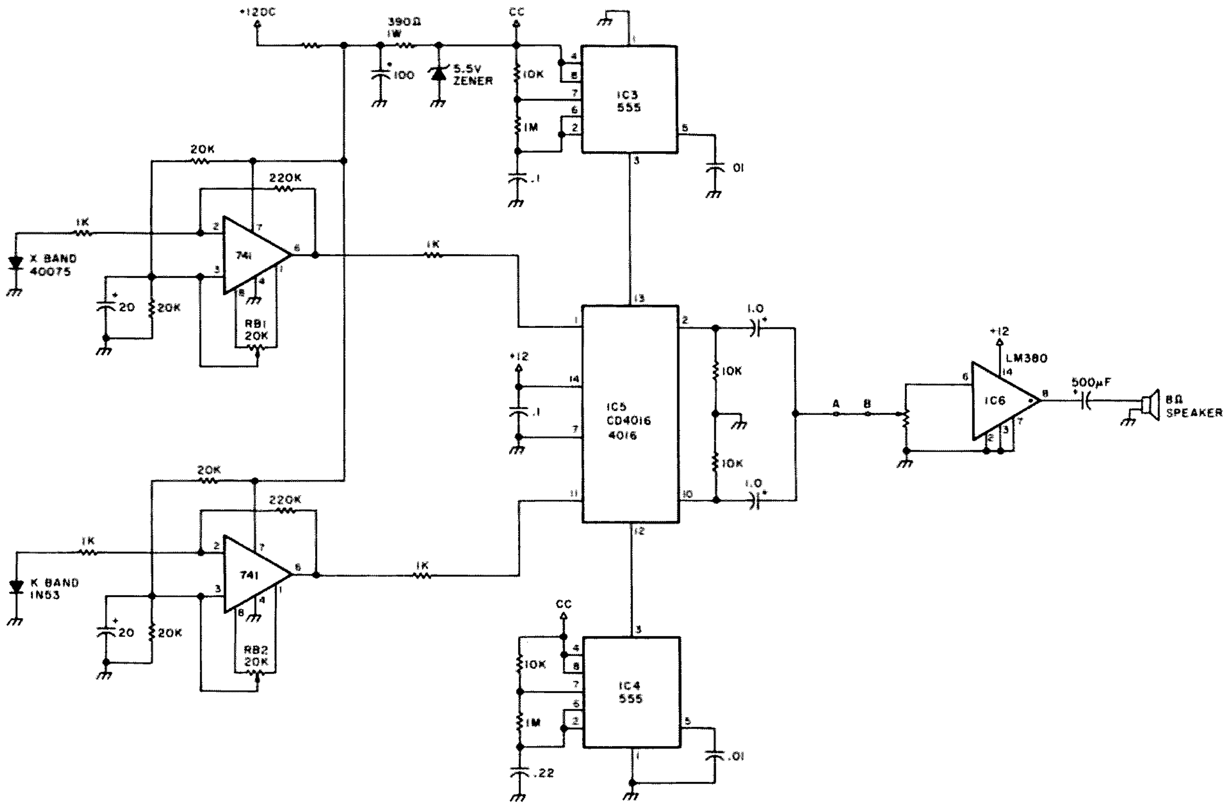

Fig. 2. Schematic, Super Scooper Smokey Detector.

of the pipe and make two marks to indicate the width of the cuts. They will be .250" wide and will support the K-band waveguide when soldered in place. Make this cut so that the .250" x .500" guide sits in place in such a way that edges of the guide mate with the H-plane walls of the K-band waveguide. Remove all burrs. (The cuts are easily made with a hacksaw, but can be better if done by a friendly machinist and a milling machine.)

No other cuts are needed in the circular waveguide, but its length is very important. The ends should be square and free of burrs. It also would be to your best advantage to clean the pipe inside and out with steel wool so that solder will easily tin the metal. Set the circular waveguide aside for now, and proceed to drill the holes in the E-plane dimension of each waveguide section.

Lay out the holes on the X-band guide as shown in the drawing. The crystal detector mounting for the 40075 X-band detector should be a 3/16" drilled hole on the centerline of the E-plane. Mark a point 11/16" from the smoothed end of the guide. Carefully centerpunch a point for the drill and drill through both walls of the guide. Open one hole to 5/16 of an inch. Place a section of 3/16" pipe or tube, 3/16" long, into the other hole.

(This pipe is found in most model shops; it is brass tubing used in model construction. If you try to buy it at a metal dealer you will pay for a lot more than you need since there it will be a one-foot section you will have to purchase.)

Solder this small piece in place so that it is just even with the inside wall of the X-band guide. This serves as a connection for the small end of the X-band diode. Now lay out the other two holes in line with the 5/16" diameter hole, drill them, and tap for 4-40 threads. Next, drill holes located 3/4" from the B tuning hole through both walls. Use a #36 drill. On the same side of the guide wall as the detector holes, open the #36 hole to a 5/8" diameter. Tap the remaining #36 hole for 6-32 threads. Deburr the hole inside and out. This hole is used to couple the circular guide to the X-band detector. Mount two 4-40x½" brass screws in the holes marked B and C and use nuts as locks for these screws. A ½" brass 6-32 screw and nut is used for the same purpose at point A.

Next, lay out the hole required on the K-band waveguide. This hole must be on the centerline of the E-plane side of the waveguide. Very carefully centerpunch a point 5/16" from a smoothed end of the guide, and at this point drill a .187"-diameter hole through one wall of the guide. Deburr on each side of the hole, as on the X-band guide. Mount a ¼" long piece of copper tube .250" in diameter. The ends should be deburred inside and out. This piece of copper serves as the outer part of a capacitor and choke for the K-band 1N53 detector diode. The copper tube and the diode are coaxially mounted, so it is necessary for the tubing to be aligned so that the hole in the guide is exactly in the center.

The next step is to lay out the 1/8" thick piece of brass which will serve as the step ridge for the K-band waveguide. Lay out the steps, cut with a hacksaw, and smooth with a file. The steps are set so that the bandwidth of the K-band cavity is quite broad and will cover many of the frequencies used by K-band radar. Departure from the dimensions given will decrease the sensitivity of the Super Scooper, so

try to stay as close as possible.

Next, in the middle of the second step from the top of the structure, drill a hole with a number 60 drill. This hole must be on the centerline of the step, and fall 5/16″ from the end of the structure so that it will align with the hole in the waveguide when the structure is in place. Remove the center conductor from a BNC chassis jack (UG-1094/U). Cut off the solder section so that the pin is .250″ long, and file it smooth. Insert the cut end into the number 60 hole and carefully solder into place. (Take care that solder does not fill the flutes on the opposite end.) This pin serves as the connection to the center conductor of the 1N53 diode—a coaxial diode that has a pin connection.

Slide the step ridge section into the waveguide so that the pin is in the center of the .187″-diameter hole. This ridge section must lie on the center line of the inside (E-plane) of the guide. (It may be held in place by wood wedges while it is soldered on the bottom to the waveguide wall.)

Now solder the X-band and K-band detector mounts in place. The 2″ circular waveguide should be inserted into the 5/8″ hole drilled into the X-band guide. The pipe should be just through the waveguide so that it is parallel with the inside wall of the guide. Solder in place. Also solder a ½″ x 1″ cover plate on the open end of the guide. Install the K-band detector mount and solder in place. Add a cover plate to the open end of this mount, also.

Now slide the horn over the end of the pipe and press down the tooth-like flaps so that they lie flat on the pipe. Match up the end of the horn with the end of the pipe and solder the flaps to the pipe. Use solder sparingly on the inside joint and make it smooth and clean, but build up the solder on the outside to strengthen the joint. Gussets may be added to the outside of the horn and pipe, if desired.

Install the X-band diode by first slipping over the diode a ¼″ solder lug and a ¼″ shoulder washer. The shoulder should face the small end of the diode. Install a 1N53 diode in the K-band mount by first wrapping the diode outer sleeve with one wrap of Saran Wrap, which serves as the dielectric for the choke capacitor. (For the purist: Use a single wrap of 1 mil mylar™.) When this diode is installed, it should be pushed into the mounting hole carefully so that the insulation is not scored. The center pin of the diode should engage in the hole of the pin jack mounted on the ridge. A diode clip should be used to connect to the shank of this diode where it protrudes from the copper tube. Use a razor blade to cut away excess Saran Wrap or mylar™ so that the clip can make contact with the outer diode sleeve.

The diodes may now be connected to the points indicated on the schematic diagram. Care must be used in making these connections. Be sure that there is no power in the circuitry. Do not solder to the diodes; solder to the lug—and then only briefly for the X-band detector diode—and do not solder at all on the K-band diode. Use a diode clip *or make a* small clamp that contacts the diode sleeve.

Assuming that all of the electronics has been constructed as shown in the schematic diagram, it is now time to test individual circuits.

The input circuits to the LM380 audio amplifier can be used as an audio circuit tracer by disconnecting the jumper marked AB at the input of the volume control. Connect a .01 capacitor to this point and use it as a probe to detect the 1-kHz tone at the output of IC3, pin 3. Be sure the audio volume control is half open, as the tone should be present at this point. Also, you should be able to detect a 400-Hz tone at pin 3 of IC4. If this test checks out OK, reconnect the jumper at AB. Now, probably, you will hear both tones. If so, disconnect pin 3 of IC4 and adjust balance pot RB1 so that the tone nulls out. Reconnect pin 3 of IC4 and then adjust balance pot RB2 until the other tone disappears. This completes the electronic adjustments.

The rf adjustments require the use of two signal generators, or your friendly police car. Apply a signal to a horn, or other radiator, from an X-band signal generator, point the Super Scooper antenna toward the generator, and use a fairly strong signal from the generator. Adjust tuning with screws B and C alternately for the strongest tone from the speaker. To use an indicator, connect an ac voltmeter across the speaker leads and adjust the screws for the greatest output. Now turn off the X-band signal generator and radiate a signal from a K-band generator at 24.5 GHz toward the Super Scooper. Adjust screw A for the strongest signal.

The adjustments are now complete, and so off to the highway! You may find that radar used at airports and military bases will be detectable. These units are putting out very strong signals and will saturate your Super Scooper. It will take only a very short time to learn how the Super Scooper works.

No description of the packaging of this device is given here. It is sufficient

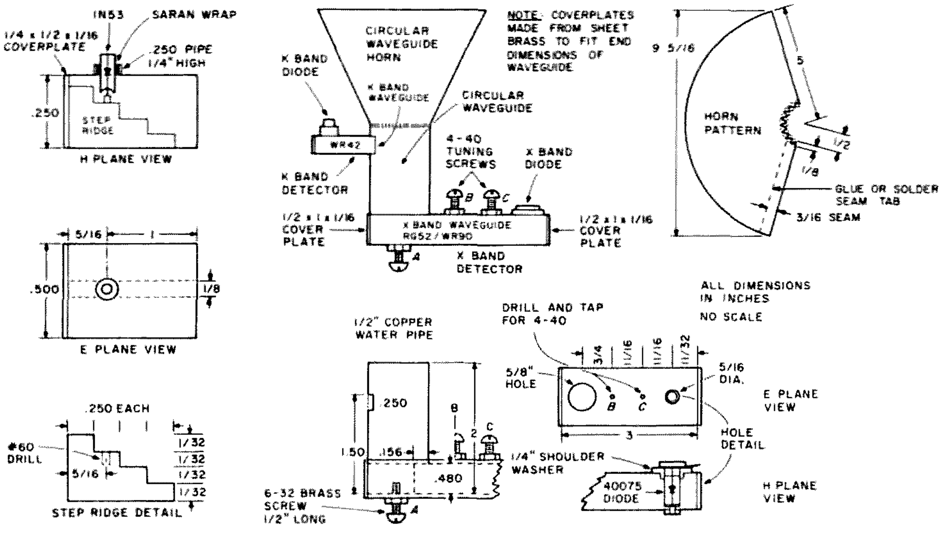

Fig. 3. Super Scooper Smokey Detector, construction details.

to say that the whole device can be enclosed in a plastic package—including the horn antenna. It is better to keep these devices out of sight, since confiscation of them does occur in several states. My unit lies on the dash, looking through the window. It is not a pretty device and does not look like much more than a batch of pipe and a funnel. Eventually, I will enclose it in a fog light to be mounted on the front bumper.

The diodes used are available from several microwave semiconductor manufacturers. Most of them cost too much for the average constructor, so the best bet is to get them through distributors. Names of manufacturers who supply either direct or through distributors appear in the reference at the end of this article.

The requirements for signal generators to tune up this unit must be left to your ingenuity. The possibility of tuning up on police vehicles is not too great, but it is a possibility. If generators are not available, it always is possible simply to try out on the road in hopes that you will find a seed trap to tune up on. Or perhaps you could build a generator. In any case, lots of luck! ■

The DXer's Secret Weapon

—costs you nothing

Chart your way to DXCC.

Having recently (finally) received QSLs from all fifty states and applied for my WAS award, I began thinking of other goals to pursue. DX came to mind.

I have been a ham since 1956, but, until a few months ago, I had never given much thought to working DX. From 1956 through about mid-year last year, my total DX was probably less than a dozen contacts (including XEs and VEs)—not an impressive record for some twenty years of casual hamming. Which brings us to my first observation about DXing:

Casual hamming does not produce DX contacts!

"So," I said to myself, "you gotta get serious if you are going to work DX."

Let's see—probably should get a linear so I can run a kW with the big guns. Gonna need a beam to replace my forty/fifteen meter vertical and that means a tower with a good base and heavy-duty guy wires. Oh yeah, some coax, some connectors, etc., etc., etc. Good grief! Getting serious about DX is going to run me into serious financial problems! There has to be another way!

After some head-scratching and a little reading in back issues of ham magazines (mostly *73*), I came up with a secret weapon for DX. With this secret weapon, my DX contacts went from a dozen or so in twenty years of hamming to seventy-four in a period of less than six months (*not* counting XEs and VEs)! If I had been making DX contacts at that rate during my previous twenty years on the air, I would have (can you believe it?) 3,040 DX QSOs to my credit by now. DXCC, here I come!

"What's the secret?" you ask. "How can I get one?!" you continue. Well, you are in luck. I am going to share my "secret weapon" with you for exactly what it cost me—nothing.

That's right, my weapon (shown in Fig. 1) cost not one red cent.

"You gotta be kidding," I can hear you saying, "that's nothing but a chart showing times in various

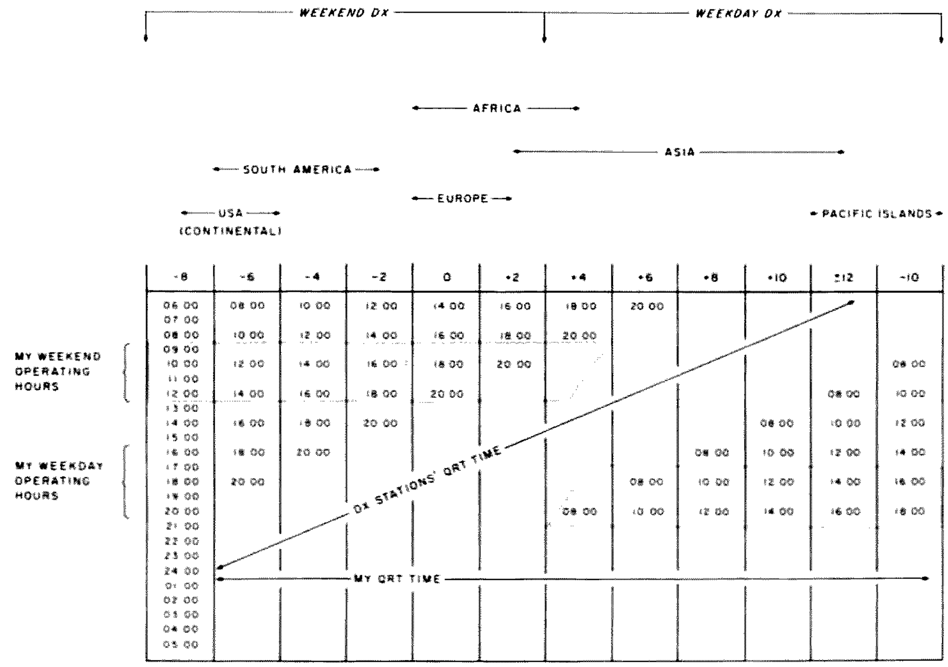

Fig. 1. Shaded areas show DX windows for my usual operating times. See text for details.

places around the world." You got it right!

I am sure that my secret weapon is no secret at all to those guys who have DXCC certificates hanging on their walls, but, for those of us who are DX novices, it can be a real discovery.

"Okay, how does a time chart help with DX?" you ask (if you are one of those who do not already know).

"Glad you asked that," I answer.

While trying to think of low-cost ways to improve my DX abilities, I reasoned that one requirement for working DX is that there have to be some DX stations on the air for me to contact. "Elementary, and obvious to the most casual observer," you say.

"Yes," I reply, "but they must be on the air when band conditions allow contact between their part of the world and my part of the world."

"So," you say, "when are DX stations likely to be on the air at the same time that the bands are open?" Your question can be answered easily, but first we have to make a couple of assumptions.

First assumption: Hams everywhere in the world probably have to hold some sort of jobs in order to buy the groceries and pay the electricity bill. Furthermore, they probably work about the same hours that you and I work: 0800 to 1700 local time, Monday through Friday. This being the case, they probably get on the air during the evenings and on weekends. (There are some DX hams who get on the air before going to work in the morning, and I salute those hardy souls and thank them for being there.)

Second assumption: The bands I work most—forty and fifteen meters—will probably be open from about 0800 to 2000 local time. I know that there are times when they stay alive all night, but these times have been rare in my experience, so I can't depend on that for DX. Besides that, I like a good solid eight hours of sleep every night.

Armed with these two assumptions (which have proven to be good enough to dramatically improve my DXing), I constructed a chart that shows my "DX windows" to various parts of the world. Here are some examples of how I have used the chart.

Let's suppose that I want to work England. Let's suppose, further, that my time zone is Pacific Standard, U.S.A. (which it is). Looking at the chart, we see that England falls on GMT (by definition). Based on my first assumption, the English chaps are going to be on the air from about 1700 to 2000 during the week. This period of time falls between 0900 and 1200 PST—right in the middle of my work day! This means that I must work Englishmen on weekends, which is exactly what I have done several times recently around 1800 GMT.

Here is another example. It has been very difficult for me to work Africa. Looking at the chart, it is easy to see why. Notice that there is only a two-hour window (1900—2000) during my usual weekend operating hours and no window at all during my weekday operating hours. It is obvious that I must get on the air earlier on weekends or stay on the air later during the week if I am going to improve my chances for working Africans. This illustrates how the chart can be useful in pinpointing DX problem areas.

Let's take a look at one more example. Suppose I want to work some DX on Wednesday starting at about 1800 PST. What DX will be available? The chart shows that Asia and the Pacific Islands will probably be in my DX window. This includes Australia, Japan, New Zealand, and Russia. I have found that the Russians get up early to get on the air, and the Japanese are on the air all the time (maybe hams don't have to work for a living in Japan!?). So, the chart says that I can work VKs, ZLs, JAs, and UAs after dinner during the week, which is exactly what I do.

I am sure you get the picture by now. DX is there to be had, and the secret is simple:

Be on the air when DX stations are on the air!

"Yes, but what kind of equipment does it take?" you ask.

Well, my experience has been that the average DX ham is equipped with a rig similar to mine: about 150 Watts input with a vertical antenna. Actually, most of the DX hams I work have better rigs than mine in that they usually have a beam of some kind. Which brings us to another observation:

For working DX, the next best thing to a time chart is a better antenna.

That is where my next investment is going. I figure that a better skyhook is the absolute best dollar investment I can make.

I don't know any big gun DXers personally, so I have not discussed my ideas about DXing with anybody who really knows how it's done. I do know that my DX count has gone up as a result of putting the chart together and using it. If you are a beginner at the DX game, it surely won't hinder you any. So why not *put* together a chart for your own time zone and give it a try?! ■

Foiling the Mad Kerchunker

—frustrate him with this circuit

How to give ulcers instead of get them.

Bill Wageman K5MAT/N5EE
35 San Juan
Los Alamos NM 87544

Repeater operators! Arise! Fight back! Show the cads you're in charge! Stop getting ulcers because some refugee from the world of little children is playing with his toy and kerchunking the repeater!

How do you feel about kerchunkers? Does the very first one get you down? Or does it take a few to wear on your nerves? Or can you stand it for hours on end? If you're in one of the first two groups, read on, but if you're in the latter group, take a ride on the Reading, and if you pass GO, collect $200—you deserve it for your patience. This article holds little for you except education about how grouchy much of the rest of the world is about kerchunking.

So what's a kerchunk? Almost everybody who has operated on repeaters for any length of time has a pretty good idea, but there are some who may not yet have been exposed to the VHF-FM equivalent of tuning up the HF-band rig on the air without any identification. It's a poor operating practice designed mostly to allow the kerchunker to see if the repeater is still alive. A more-or-less quantitative definition (one that is necessary for this exposition) of a kerchunk might be stated: "A kerchunk is an unidentified key-up (or transmission) of short duration on a repeater input frequency." Most kerchunks are well under one second duration.

With a decent definition of a kerchunk, we may now think about how to design a kerchunk detector on the repeater. Once you have the ability to detect these strange creatures, it's feasible to try to do something about them. What a guy cares to do depends heavily on the situation, but let's look at a few of the possibilities.

You can ignore them altogether if you can stand it. There is a minor question about the legality of continually repeating unidentified transmissions, but that's not the point. You can listen to the kerchunking for a short time and then shut off the repeater

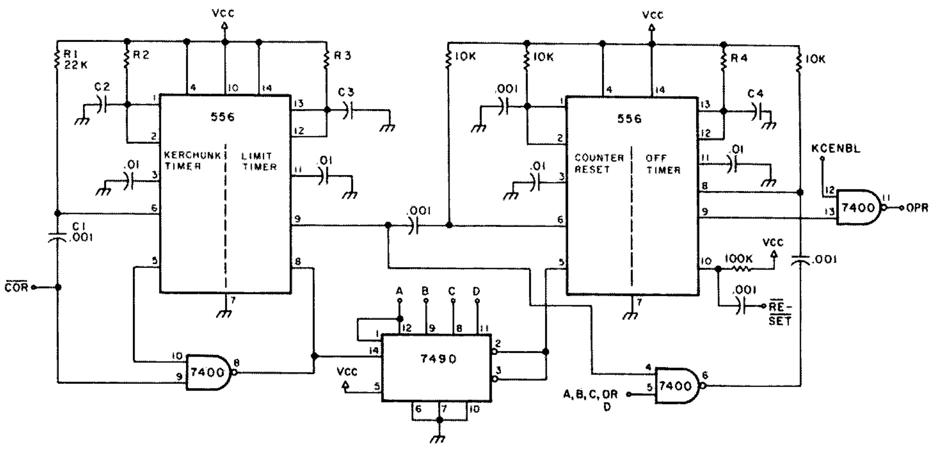

Fig. 1. Schematic diagram.

for awhile. This denies repeater access to everyone, of course, but could result in a certain amount of "peer pressure" on the guilty culprit(s). You could also, on the first kerchunk, measure the incoming frequency (assuming there's a discriminator on the repeater), and then lock out only those incoming signals near that frequency. This solution is still not ideal, but it is already quite difficult to implement unless you have a microprocessor-controlled repeater, so I have chosen the middle course.

Let's suppose, for purposes of discussion, that the control logic in your repeater is TTL-compatible. If not, you will have to use whatever level shifters that are necessary to make this true. Please note in the discussion that I have assumed certain stated active signal levels—yours may have to be inverted.

So, somewhere you have a squelch-operated control signal. I'm assuming that when the squelch is closed you have a TTL high, and when it opens you have a TTL low. Let me call this signal $\overline{\text{SOS}}$, for NOT Squelch-Operated Signal. The overhead bar, or the word NOT, means the active signal is a low. If we capacitively-couple $\overline{\text{SOS}}$ to the input of a 555 timer (or ½ of a 556), that timer will be triggered whenever the squelch opens, and its output will go high. If we NAND the output of the timer with the $\overline{\text{SOS}}$ itself, it's evident that if the squelch closes *before* the timer goes low, we'll get a TTL low out of the NAND gate. Thus we have a kerchunk detector—if the key-up is shorter than the timer period, it's a kerchunk.

I have chosen to do two things with this signal. It increments a counter and starts another timer, which I'll call the limit timer. When the limit timer's period is up, it triggers a third timer which then issues a short reset pulse to the counter. We clearly don't want to shut off the repeater because it was kerchunked once on each of four consecutive days!

However, the output of the limit timer is also NANDed with any one of the four outputs from a 7490 decade counter. If the one output is chosen, only one kerchunk is needed to cause the output of the NAND to go low. If the two, four, or eight output is chosen, then it will take two, four, or eight kerchunks *during the limit timer's period* to cause the output of the NAND gate to go low.

This signal is capacitively-coupled to still another timer, the off timer. This timer gets set when the NAND goes low, and its output stays high during its period, which may be anything you like. I have NANDed this timer's output with a TTL control signal I've called KCENBL (*K*erchunk Circuit *EN*a*BL*e). This is a signal that must be provided by your control circuitry to enable (high) or disable (low) the anti-kerchunk circuit. If you don't want to mess with this sort of thing, just tie that pin to Vcc through a 1k resistor so that the circuit is always on.

The output of this gate might be called OPR, for *OP*e*R*ate. When this output is high, the repeater is allowed to go on and off freely with the squelch, and when the output is low, the repeater is disabled. If you need the opposite polarity to disable your repeater transmitter, it's easy enough to run this signal through an inverter. Note that the fourth NAND gate in the 7400 can be used as an inverter for either the input or the output signal, if necessary.

There is a desirable fourth connection to your repeater-control logic, called $\overline{\text{RESET}}$ (NOT RESET). A TTL low on this line will reset the off timer to zero, independent of how long it has been on (the repeater has been off). This allows a control operator to immediately defeat the anti-kerchunk circuit without disabling it.

Some of you are undoubtedly griping that I did not consider part of my definition of a kerchunk when I designed this circuit. I said a kerchunk is an unidentified key-up. So, in reality, one should check to see whether or not audio is present on the signal before assuming it's a kerchunk. I chose to ignore this aspect because I felt it was not all that important, it would be easy to defeat with a Bronx cheer, and the timing of the kerchunk detector I used is so short that it is unnecessary. If you have read this far you probably have the knowledge to add audio detection if you want. That first gate could be made into a three-input NAND gate and appropriate audio detection circuitry added.

The component values given in Fig. 1 are recommended as a first try and should be satisfactory if you are actually using TTL logic. R1 and C1 may have to be increased to give more reliable triggering if $\overline{\text{COR}}$ is not a good square wave. R2 and C2 form the time constant for the kerchunk detector, which may be anything you like within reason. Choose the Rs and Cs for the timers by the formula $t = 1.1\ R\ C$, where t is the desired time in seconds, R is the resistance in Ohms, and C is the capacitance in farads. My version defined a kerchunk as a key-up of less than about 200 ms, so any audio present is essentially irrelevant.

R3 and C3 define the limit timer period. I chose a value of around 30 seconds, but almost any reasonable period that strikes your fancy is OK. The reset timer period is 10 microseconds and should be adequate for any TTL counter.

How long do you leave the repeater off? R4 and C4 determine this length of time, and I chose five minutes as a reasonable off period.

It is desirable to use good engineering practices when building any logic circuit, particularly when it will be used in what might be called a hostile environment. Be sure to do proper bypassing and shielding, or glitches will be your companion-control operator! Mechanical relays somewhere ahead of the circuit could easily have contact bounce problems that would make *any* transmission appear to be a series of fast kerchunks.

There are two problems I see associated with the use of this sort of thing. It is not desirable to deny everyone the use of the repeater just because someone is discourteous to his fellow amateurs. Some of the worst offenders are likely to get their kicks by using this device to shut off the repeater so others can't use it! It is also undesirable to have a repeater "kerchunked" off by a fluttering mobile signal. Neither of these problems is easily solved unless a microprocessor logic element is available—but that's another story.

I would like to thank Bob Cowan K5QIN, trustee of the Los Alamos Amateur Radio Club repeater (WR5ABU), who kindly permitted a shakedown cruise of this circuit, and the club members and repeater users who put up with the whims of a guy who wanted to see if anything short of murder could effectively discourage kerchunking. Remember CRANK: Courteous Radio Amateurs Never Kerchunk. ■

Trends in Surplus

—it's not what it used to be

Don't give up hope.

Radio amateurs reaped one of the first big benefits from surplus electronics. This bonus first appeared after WWII, when there was lots of surplus military equipment on the market, and lasted well into the fifties. Many of the rigs sold only needed simple modification to get them on the ham bands. There were plenty of small parts available for the builder, too.

To a large extent, this has changed. There is less of the wartime surplus available, and the prices are not all that great. Also, it is many years old now and behind the field in several cases. We were spoiled by its simplicity. There is no equivalent now. There just is not that much modern surplus military equipment for the ham. And the prices are higher for what there is.

The situation looks bleak. Actually, it looks bleaker than it really is. There is plenty of surplus available, but the field has changed. While there may not be the dream rig just waiting to be picked up for a song, there are entire categories of worthwhile surplus that can be of great benefit to the amateur.

It should also be pointed out that the amateur is no longer the main user of surplus. There are schools and industries, as well as electronics hobbyists, using surplus now. It may help someone who would like to start taking advantage of this to outline the main categories of what is available and where it might fit into his plans.

Many still think of surplus as being synonymous with military surplus. There is still military surplus available, and newer equipment being released, too, but probably the biggest category of surplus is industrial surplus.

Let's start with the military. There are still the older tube rigs available from the war and the fifties. It is mostly the receivers that are eagerly sought, some of them perhaps more eagerly than they warrant. You can pick up a rugged, solidly-built receiver that will do workhorse service for you. You can also buy some that are extremely hard to service. For example, the R-390 series is highly regarded but difficult to maintain. Parts are a real problem.

There are also a number of tube-type components still available. This goes for high-power projects and so forth. You may have problems finding a reliable source for inexpensive small parts for a tube project, though. There is some newer solid-state military surplus coming through, but at a higher price than what makes surplus buying attractive.

The next biggest category of military surplus would be test gear. You can pick up some military versions of civilian gear at a low price. However, this may not be what you need. Much of this is lab-grade gear, which sounds nice, but if it needs any sort of servicing to be put back in order, you may have problems. You could wind up with something that you can't even use. Here you have to weigh your troubleshooting experience and your test bench.

It is schools and smaller industries that benefit the most from this if they can check out the gear themselves. They may wind up with additional equipment at reasonable cost with the addition of just their own time and expertise.

In the same way, there is industrial surplus of ready-built test gear, too. Unless it has been gone over for you by the seller, you have the same problems as with military surplus. If it doesn't work right, can you fix it yourself?

There are a few hidden pitfalls with much of this gear. A lot of the postwar

gear uses the early printed circuit boards. A lot of it received continuous-duty service. That and age have done things to those PC boards.

When you go to work on them, you may find that the board itself has deteriorated to the point where it causes intermittent problems (the foil may be starting to peel), and that adds up to a service headache.

A lot of equipment is of hybrid design—mixed tubes and transistors. Since it is precision gear, the tolerance is important. By this time it is long out of tolerance. The cost to start at the beginning and bring all the sections up to tolerance may be so out of sight as to be impossible. If the cost doesn't get you, the lack of available replacement parts will.

The use of mixed tubes and transistors, particularly circuits that mix both together, represents a careful blend of the worst features of both tubes and transistors. That means you will be trying to make an out-of-tolerance circuit function well. Hybrid circuits are more difficult to service at best. Often these circuits were riding right on the edge of a usable state-of-the-art technology. They were apt to have very little tolerance for variation even when new. Trying to get them to function as out-of-tolerance circuits may not be practical.

The used, unchecked price may look very attractive, but can you fix it? The checked or good condition (working) price may not be that good when compared with a new, or kit, price for gear that may be simpler, but will do the actual job you need. A rule of thumb would be that you should have at least equal or better grade gear and expertise than you are trying to service.

That's the part that looks so bleak. Where is the nice, easy, and cheap part? Well, it's all in how you look at it. There are areas which are electronic heaven for those who can use it. These are in the field of industrial surplus. First of all, how do you feel about solid state? This is where the action is. In fact, the values here are often even better than the values that are fondly remembered from the late forties and fifties.

Solid state is mostly low voltage. It also becomes obsolete almost instantly. Manufacturers dump it by the ton. Just two examples: A 1967 catalog listed the SN7400 for $6.50 each and the SN7490 for $23.20. Now you can get the SN7400 for about 16¢ and the SN7490 for about 45¢. That's a few cents on a dollar. And those 1967 prices had come down quite a bit from the original prices. In that field, individual solid-state devices of all sorts have been priced lower, and the small parts to go with them are available at comparable prices. This takes care of transistors and digital ICs, but there is more. Even though they are newer, consumer-oriented ICs are also on the surplus market. You can not only buy some of the older consumer ICs, but also some that are still in use commercially. This gives you whole sections of equipment.

You are familiar with the audio amps and preamps. There are also rf sections and specialized ICs available, and are they ever cheap.

For what is available, you can often build a transistor or IC circuit for much less than an experimental tube circuit of the same type. Power supplies are always a high-cost item with tube work. With transistors and ICs, there is so much available in parts and built supplies that the cost is not a major factor. There are lots of rf transistors and power types available for the experimenter, so in that area you can work with some reliability.

While tube parts are hard to come by, this is really only in one area. Old-style tube thinking is expensive, but there is one way that you are ahead of the game. Take advantage of the state-of-the-art in tubes. What? You didn't know tubes had changed? Then you haven't had to work with TV sets much lately.

There is a lot of tube technology designed for use in TV sets. This hinges on a line-operated supply (mostly without a transformer) of about 100-200 volts. The TV tubes are built to work well in this range. There are lots of modern compactron multisection tubes that hams and experimenters have yet to touch. And the benefits from them are great. There are plenty of low voltage parts for receiver and TV replacement use around, even in surplus. There are also many power supply transformers and parts available, too. This puts a tube circuit cost on a par with transistor work. The initial capital cost for bench supply and some parts will be slightly higher, but once you have them, you have them, and the difference is only a few dollars.

So you still have the option of going tube or transistor at a reasonable experimenter's price. Keeping to receiver voltage levels is the key. Once you go above that voltage range, the price goes up fast.

There is still more. There are a few areas of specialized surplus to explore. The computer field did not just dump a few measly ICs on us. There is also ready-built computer equipment. To name a few items, there are power supplies, keyboards, video terminal units, and whole sections of standard business equipment oriented towards computer interface. If you know what it is and what to do to get it going, there are bargains for the knowledgeable.

There are some other areas of commercial surplus, too. These are more consumer-oriented. Many brands are really the same or similar equipment bought from other manufacturers. There are lots of hi-fi-type components and semi-complete equipment that can be utilized with little work. These prices are often quite low.

In short, there is another renaissance of surplus upon us, but the times and technologies have changed. With some work to update and upgrade your basic electronic knowledge, much is adaptable to ham or other experimental uses. There are a few gaps that make it a bit rough on some types of building. These make it seem as though there is not much available for building. Hams in particular are bothered by this, as certain key items are just not right at hand at surplus prices. A big headache is tuned circuits. It is hard to get the coil stock which used to be a part of every project. The slug-tuned coils are hard to find, too. There are sources, but the price is at a premium. There are ways around this; however, there is another problem.

The other half of the tuned circuit is a variable capacitor. The usual small variable with a shaft for a knob is not that common or available these days. This makes all sorts of tuned circuits for receivers and transmitters hard to build, particularly when an author uses a specific part in an article. There are ways this might be eased. There are easily-available

sources for toroid cores and information on using them in circuits. They are not that common in construction articles, though.

Tuning can also be done with varactor diodes in many circuits, but this is also not common in many articles. Other parts are also not common. The modern i-f strip parts, such as crystal or ceramic i-f filters, which are quite cheap for manufacturers, have not shown up on the surplus market. The standard receiver i-fs, in particular, are hard to come by. Even the older-style transistor i-f transformers are not common items. Many construction articles use very expensive and hard-to-come-by filters for construction. There are few simple alternatives given. Power stages are always a problem. When the voltage or power goes up, the price goes up and the item becomes hard to come by.

Some ham items have benefited from all of this technology. The frequency counter as a ham item is so new that it is still considered exotic, and yet in the few years since it hit the ham market, the price has dropped steadily. At first, they had to be home-built to get any price break, and they were fairly expensive then. Now you can buy kits and ready-built units for less than you can build your own.

A counter that would have cost industry thousands just a few years ago costs a ham a few hundred. A less-costly unit will still be more accurate than any frequency standard available to hams up to now.

However, we still have the problem that our basic purpose, communications equipment, is not so easily served by the surplus market. The nearest thing to it is the conversion of CB gear to ten meters. That may catch on in quantity, but in the meantime it's more symbolic than a major force.

This apparent lack in modern surplus should not really be such a major problem. What it means is that we have not yet solved some of the technical problems in utilizing what is available for our more common amateur uses.

This is what is called a culture lag. The material is there, but we have just not fully adapted it to our purposes.

It would seem likely that in the next few years there will be some breakthrough in the use of modern surplus that will bring a time of simple but effective home-brew ham gear. This will probably have an effect not unlike that of the coming of the available frequency counter. In particular, it will put equipment within reach of many who are not able to spend much to get started. There is very little simple rugged equipment at a beginner's price, particularly equipment that can compete in real performance with the store-bought.

That's the big problem. Even for the same money, there are few who could build a receiver that would actually work as well as a commercial kit or ready-made unit.

Better utilization of the available surplus now, and what may become available in the next few years, should produce projects where the cost, complexity, and availability vs. performance ratio should be favorable enough so that it will be a tangible inducement for many more hams to build some of their gear again. ■

An 8080 Repeater Control System

—part IV: addenda

Several additions have been made to the control system. The LM309K regulator IC in the +5-volt power supply has been replaced with an LM323K-5, which has a higher current rating. An "old code" command has been added to the program, the Mohawk Message Repeater has been swapped for a standard 8-track player, and a telephone switchover network has been added to share a single telephone line with two repeaters.

2#1 Message

You are hearing an amateur radio repeater. Very simply, a repeater consists of some electronics equipment which boosts radio communications range. A repeater has a receiver and a transmitter operating on different frequencies. They utilize antennas located as high up as possible. Because of the high location and very good quality equipment, repeaters can receive transmissions from much further away than can be normally done and can be heard at a further distance than is commonplace. The repeater retransmits weak signals, permitting walkie-talkies and mobile stations to communicate with each other up to a hundred miles apart or more, when without a repeater, the range may be only several miles or several tens of miles.

Repeater operation is but a small part of what is available to the radio amateur, or ham, as he is commonly called. Hams routinely talk to other hams around the world on the shortwave bands. Some operate the international Morse code and others use single sideband, a modern form of voice communication. Many hams operate radioteletype, and some even transmit pictures across continents. There are some amateurs with fast-scan television stations of their own.

Ham radio is a fascinating hobby. Some hams like to build equipment and some just like to talk, but most do a little of both. Hams keep up with the ever-growing technology of today. Amateurs built several satellites, had them placed into orbit, and can now easily communicate through their very own satellites, called OSCAR (for orbital satellite carrying amateur radio). Some hams even have homemade computers completely running their stations!

Amateurs have a lot of freedom to operate on the air and build their own equipment. This is because each and every ham must demonstrate to the Federal Communications Commission before receiving a license that he has an understanding of both radio law and electronics theory in addition to knowing the international Morse code.

Ham radio is both a fun and an educational hobby. If you think that you could develop an interest in ham radio, contact the Baltimore Amateur Radio Club at PO Box 5344, Baltimore MD 21209. Or dial H-A-M-T-A-L-K, HAMTALK, on your telephone for further information.

This has been the two-pound-one message. Two-pound-two gives general information, two-pound-three supplies current club information, and two-pound-four explains more about the repeaters.

The Old Code Command

The Baltimore Amateur Radio Club changes its autopatch access code annually. I added the old code command to make it clear to users that their touchtones™ were accepted, but that the old access code was used and no longer activates the autopatch. When the old code is used, after the carrier drop, the control system sends "OLD CODE" in CW.

The programming is simple, and Listing 1 shows this routine. The routine calls WCD, loads the HL registers with the message address, and CW is called. In the code table, the old access code now points to OLDCD.

The Tape Loop

The tape machine described in Part I developed a problem, and the opportunity was taken to replace it with a common 8-track tape player. This is most suitable because a loop configuration is required. The primary drawback to the Mohawk Message Repeater was that the recorded message had to be exactly as long as the tape itself. The new system is

2#2 Message

Welcome to the Baltimore Amateur Radio Club's 07/67 repeater, WR3AFM. The transmitter is located at the old WBAL tower on Park Heights Ave. The repeater has receivers north of the beltway on Old Harford Road, at the WRBS tower near I95 south and the beltway, downtown at 4000 North Charles Street, at the QTH of K3VC and N3JC at the top of the Jones Falls expressway, and a fifth receiver in Randallstown. A voting selector feeds the best signal to the transmitter.

At the transmit site, there is also a duplexed 440-MHz repeater, 444.35 in and 449.35 out.

You will note that a short click is heard after releasing your carrier. This signifies that the repeater timer has been reset and leaves time for breakers. It is not necessary to let the repeater carrier drop. 07/67 has an autopatch limited to travelers and club members, though open to anyone for emergency traffic.

The repeater is set up to block touchtone signals from repeating. There are several codes that anyone is welcome to use after proper identification. One-pound-one links the 67 machine with the 440 repeater. To acknowledge that function, the repeater sends an "R" in Morse. The repeaters remain linked until a star is sent, again acknowledged with an "R". Two-pound-one plays a tape giving a brief introduction to ham radio. Two-pound-two gives this recorded message. Two-pound-three supplies current club information. Two-pound-four gives more information about our repeaters. Tape messages can be activated at most once every ten minutes. Three-pound-three will disable the repeater's blocking function until the carrier is dropped, permitting the tones to be repeated. Any touchtone digits sent after four-pound-four will be verified in Morse after the carrier drop. Five-pound-five will repeat what was sent during a four-pound-four operation, or the telephone number dialed during an autopatch, whichever was last.

The control system for the repeaters is an 8080-based microprocessor which performs the various functions, including multiple identifications as well as redialing telephone numbers for the autopatch.

The Baltimore Amateur Radio Club has another two meter repeater, 34/94, which is a split-site repeater in the Northern Baltimore area. We hope you enjoy the use of our repeaters, and we would like to see you at our meetings the first and third Wednesdays of the month at the Ames Methodist Church in Pikesville at 8 pm. Listen for interesting bulletins weekdays on 67 at 7:30 am and rebroadcast on 94 at 6 pm. Code practice can be heard Mondays at 9 pm on 34/94. Should you desire to contact the club, write the Baltimore Amateur Radio Club, PO Box 5344, Baltimore MD 21209.

2#3 Massage

This is the two-pound-three message. Two-pound-one gives an introduction to amateur radio, two-pound-two supplies a generalized message, and two-pound-four provides information about the repeater equipment.

This repeater is sponsored by the Baltimore Amateur Radio Club, PO Box 5344, Baltimore MD 21209.

Where is the current DXpedition? What is the WWV propagation forecast for the upcoming week? When is the next local hamfest? To find the answers to these and other questions, listen to the BARC bulletins weekdays at 7:30 am on 07/67 and at 6:00 pm on 34/94. Keep up with your hobby.

(In CW at 35 wpm: Hams constantly strive for proficiency with CW.) Code practice sessions are held on Monday evenings at 9:00 on 34/94. Call in your requests next Monday night and test or improve your code speed.

Remember to dial H-A-M-T-A-L-K, HAMTALK, in the Baltimore area for current information. Spread the number around to your non-ham friends.

Don't forget to write an article or two for the club magazine, the *Modulator*. If you can help out with amateur radio classes, contact W3HYY.

Is there something that you can do or suggest for the club? Come to some meetings and volunteer—we'd love to have your participation.

BARC meetings are held at the Ames Methodist Church in Pikesville at 8 pm. Business meetings are held the first Wednesday of the month. General meetings include a presentation and are held on the third Wednesday of the month. Everyone is welcome at both meetings.

The September meeting will be a discussion of spark-gap transmission and ham radio of years past. The October meeting will be a tour of the Emergency Medical Radio Service at Sinai Hospital. November's meeting boasts a talk on radio-controlled models. The January meeting will be the annual BARC auction, the February meeting will have demonstrations of antennas and their patterns, and the March meeting will be all about our repeaters. Try to join us at these meetings, if possible.

more versatile and allows the message to be any length up to the length of the loop itself. Since the tape player is stereo, it is convenient to place the message audio on the right channel and a tone on the left channel to indicate when the message is finished. Standard 40-minute tapes supply 10 minutes per track. The control circuitry activates the drive mechanism upon request, and when the message is done and the tone is encountered, the tape system disconnects itself from the repeater and continues running until the metallized strip signifying the beginning of the tape is reached, shutting off the machine. A bonus is that the tapes can only be activated once every ten minutes. A KILL command has been added to allow termination of the tape message when desired.

The tape player has four pairs of tracks, so this feature was exploited to provide four different tape messages. The original single 2#2 tape request is expanded to four, accessible via the codes 2#1, 2#2, 2#3, and 2#4. The microprocessor remembers which track the tape player is on and advances the head assembly to the requested tape track. The 2#1 message is for non-hams. It briefly explains what amateur radio is all about and is useful when someone asks what your handie-talkie is for. 2#2 is a shortened version of what it was before. 2#3 supplies current club information: net schedules, meeting programs, etc. The relative availability of 8-track recorders permits monthly updates to be made. The 2#4 message is a more detailed description of the repeaters.

Fig. 1 shows the tape loop interface. This circuitry is built into a minibox and mounted to the tape player. The only connection between the tape player and the control system is the 16-pin DIP plug as before. The tape player is a standard 8-track designed for automotive use and operates from a 12-volt power source. Ac-operated players could be used with the addition of a relay to connect the unit to the ac line from a 12-volt coil. The circuit is quite simple. Relays K1 and K2 provide the switching logic. Normally, both relays are de-energized. When the start pulse from the processor grounds the floating half of the K1 coil, the relay pulls in. The SENSE contacts on the

player are normally open, so the sensing transistor is normally low. This allows K1 to latch, supplying power to the tape player.

The PTT line is grounded only when K1 is activated and K2 is not. Likewise,

2#4 Message

WR3AFM consists of two separate repeaters: a 440-MHz repeater and a two meter repeater. The 444.35/449.35 repeater is a duplexed single-site repeater. The 07/67 repeater consists of five repeaters spread around town with the common input frequency of 146.07 MHz. These satellite receivers transmit via 440-MHz link frequencies to the 146.67 transmitter site. Each link has a Station Master antenna, a 146.07-MHz receiver, a 440-MHz transmitter, a control shelf, and a CW identifier. The IDer is required to satisfy FCC requirements, and for our purposes they continuously identify with a low-level, low-pitch tone. This can be used to determine which receiver has been selected.

At the transmit site, a voting selector chooses the best signal from the five links and sends it to the 146.67-MHz transmitter. The transmitter drives a 250-Watt amplifier, though only a portion of that power reaches the Station Master antenna through about 500 feet of feedline. All of this equipment is of the General Electric MASTR series.

The repeater control is performed by a dedicated 8080 microcomputer system. This consists of 57 integrated circuits and has 3K bytes of ROM, 256 bytes of RAM, seven eight-bit output ports, and three eight-bit input ports. The control program is over 1500 lines long. The 8080 accomplishes the user codes, the autopatch, and permits elaborate control options to be accessed via touchtones remotely.

The 34/94 repeater is also a split-site repeater. The transmitter is in Towson and directly feeds a Station Master antenna. The receiver is co-located with the 07 receive link at the Charles Street site. The 07 and 34 receivers share the same antenna. Therefore, the coverage of 07/67 necessarily engulfs that of 34/94. With the exception of the link transmitter, which is a Progress Line, the 34/94 equipment is all General Electric MASTR. It is necessary to wait for the beep to reset the three-minute time-out timer. Additionally, on 34/94, it is required to let the entire repeater carrier drop once every twelve minutes. This is because the drop delay is on the link transmitter, which causes it less wear and tear.

This has been tape message two-pound-four; two-pound-one gives an introduction to amateur radio, two-pound-two supplies a generalized message, and two-pound-three provides recent club information.

audio is available only under the same conditions. At this point, the tape is running, the repeater is keyed up, and the tape audio is feeding the transmitter. The right and left audio channels have a 10-Ohm load resistor to protect the audio output stages. The left channel is stepped up in voltage, rectified, and fed to a tone-detect transistor. Most of the left channel is empty. At the end of the message, a tone of almost any frequency is placed on the left channel for five to thirty seconds. The tone-detect transistor detects the tone and activates K2. Immediately, the PTT and audio lines are released and the repeater is freed up. K2 latches through the grounding contact. Both relays remain latched, continuing to power the tape player, until the metal foil on the tape reaches the SENSE contacts. This unlatches K1, which releases K2, and all returns to the rest mode.

The track solenoid in the tape player usually requires several Amperes to drive it. Relay K3 drives the track solenoid and is driven by an open-collector output bit on the processor. This permits the processor to control the track-select mechanism. A ground on the KILL line simulates the beep tone, killing the tape message. A 12-volt power supply is included to power the unit. The tape player must be modified by breaking the leads on the SENSE contacts and the stepping solenoid and bringing them out separately.

A considerable amount of software is necessary to control the multiple-track tape system. The system works by dead reckoning; the processor maintains a memory of which track the machine was last on and advances the track until the desired one is reached. A better arrangement would utilize a tape machine which has individual lamps to indicate the track. These signals could be sent to input ports of the pro-

cessor, and it could advance the assembly until the desired lamp was activated. I chose not to use this approach because the tape players with the added track lamps are not as readily available as the

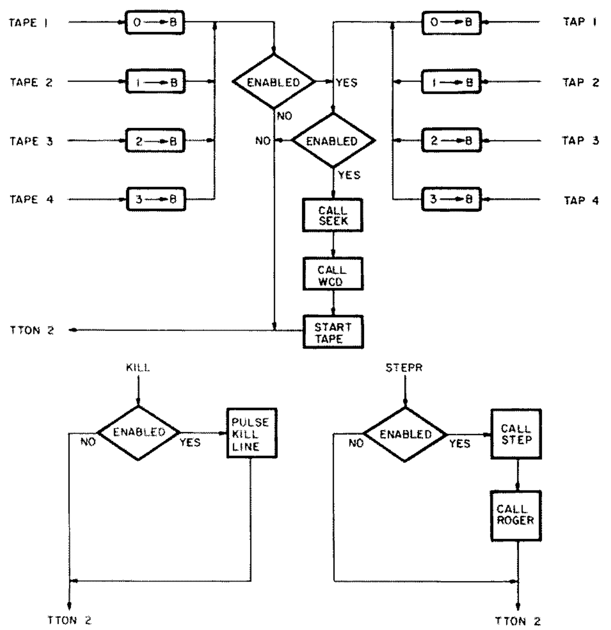

Fig. 2. Tape commands.

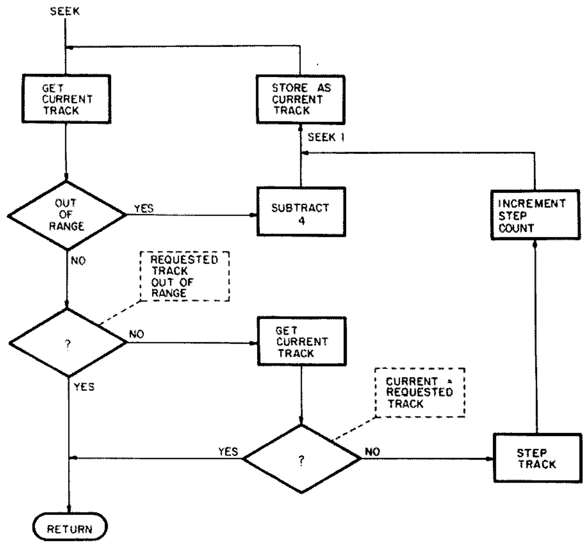

Fig. 3. The SEEK subroutine.

ones which do not have them. There has been little problem with incorrect track selection.

Listing 2 shows the tape-handling software. The four commands, TAPE1, TAPE2, TAPE3, and TAPE4, correspond to the 2#1, 2#2, 2#3, and 2#4 codes. Commands TAP1 through TAP4 correspond to the 2*1 through 2*4 codes for use by control operators. TRACK is the variable which specifies the current track. Upon initialization, TRACK is set to 1, corresponding to track 2. This is because 2#2 is the most commonly used message, and, after a power failure, presetting the program to that track gives the highest probability that the processor and the machine are in synchronization.

Fig. 2 shows the various tape commands. Register B specifies the desired track for the SEEK subroutine. The KILL command pulses the KILL line to the tape circuitry, stopping the message. The STEPR command steps the tape track and acknowledges with an "R". This is used to resynchronize the machine and the processor.

The SEEK subroutine is shown in Fig. 3. SEEK advances the head assembly until the desired track, passed in register B, is reached. Validity checks are made to prevent possible erroneous requests from pulsing the track line for long periods of time.

The Switchover Board

Our 449.35 repeater has separate autopatch circuitry, and we had been using a second telephone line for it. To economize, we decided to utilize the main 146.67 autopatch line for the other repeater. The telephone switchover board decides which repeater is to have access to the telephone line. The phone line rests on the main control system, allowing control over the system via the telephone and permitting two meter autopatches. When an autopatch is requested on 444.35, if the line is not in use, the line is switched to that machine. The line remains there until the autopatch is terminated. The telephone line will only be given to a repeater if the other one is not using it at that time. If the request is not granted, a simulated busy tone is generated and sent to the second requesting repeater. To accomplish the remote base function on the 449.35 repeater,

after dialing into the control system, the code 59* is sent. This switches the telephone line to the 449.35 repeater for 10 seconds. During this period, signals present on 444.35 will be heard on the telephone. If the autopatch code is sent before the ten seconds elapse, the autopatch will be activated, the remote base function is realized, and the line remains latched until killed.

The switchover board is shown in Fig. 4. The relay is normally relaxed and passes the phone line to the control system. Two 555s generate the busy signal. The 10k potentiometer sets the level of the busy tone to the repeaters. A single D-type flip-flop handles the switching logic. The flip-flop is CMOS and drives a Darlington transistor which drives the switchover relay. The numbered connections go to the phone connector on the main control system. If the processor grounds the GRAB line, the telephone line will remain on the control system no matter what. When the processor pulses the 450 REQUEST low, the ten-second timer is actuated, switching the phone line to 449.35. When an autopatch request is made on 444.35, +12 volts is present on the 450 AP line. The AP+RB+PHC line coming from the processor board signifies that the phone line is in use.

The software to implement the 59* command is shown in Listing 3. The 450 REQUEST line is pulsed low, and the command exits.

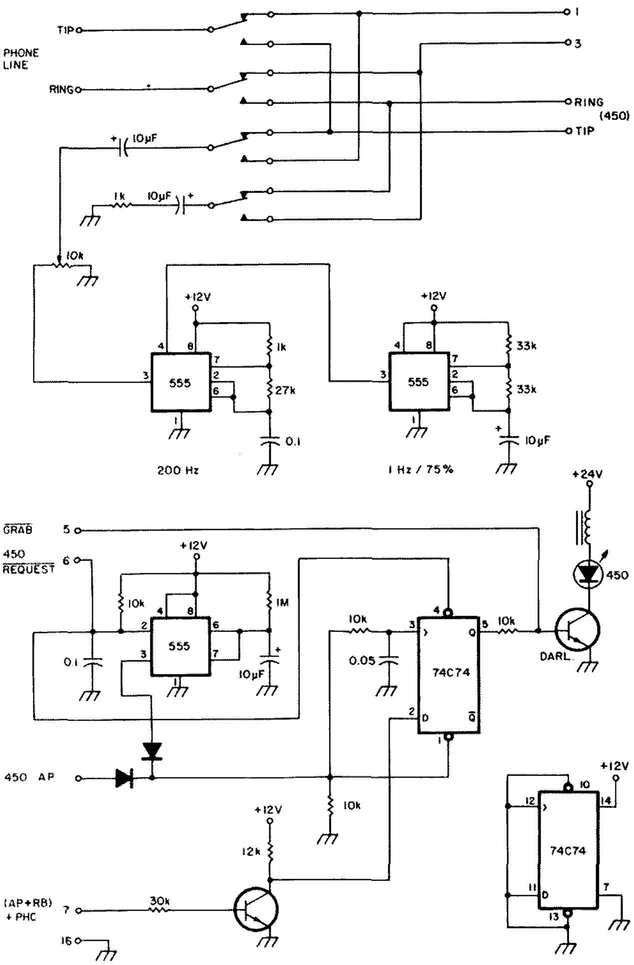

Fig. 4. Switchover board.

Main Board Modifications

A small amount of wiring must be added to the main board to permit the new circuitry to operate. The new connector wiring is shown in Fig. 5. Two diodes are used to create the AP+RB+PHC signal required.

Software

The software patches described may be included in full or in parts. It may be possible to fit the additions in the space remaining in the second ROM, depending upon how much space is taken up by the four different IDs and the single-digit telephone numbers. However, for us, it was necessary to expand to a third ROM. The last ROM is only about one-third utilized, so much more can be added before it becomes necessary to wire in a socket for a fourth ROM.

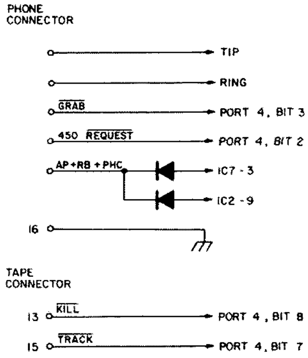

Fig. 5. Modifications to processor board.

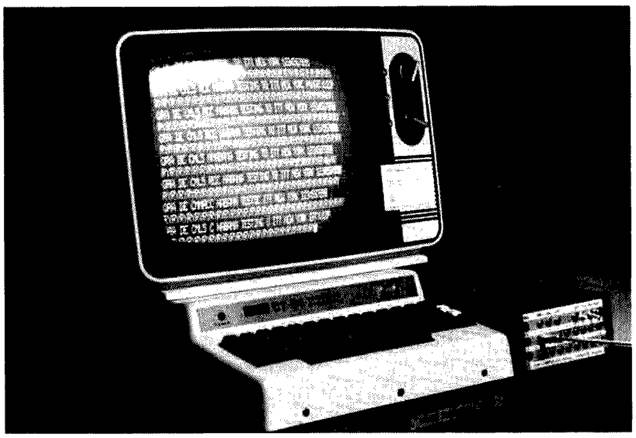
RTTY Transceive for the KIM-1

—requires video terminal and AFSK generator

No noise, no oil.

Several good articles have appeared here in the pages of *73 Magazine* concerning the use of the KIM-1 microprocessor for RTTY work.[1,2,3] This article describes an easy-to-use program for RTTY transceive when teamed with WA5DXP's article.[1] It requires no additional memory for the KIM. It is also designed as a "stand-alone" program for RTTY transmission at all standard amateur RTTY speeds.

Basically, what we desired was a complete RTTY station without the need or bother of mechanical printers, TDs, or reperforators. The resultant system sends and receives RTTY at 60, 66, 75, and 100 wpm and has a built-in buffer for "auto-start" transmissions, auto-shift between Baudot letters and figures, and, finally, a built-in ID for the end of transmission. The program does not need to be manually stopped to switch between transmit and receive and back again. The resultant system is straightforward to use and totally silent.



Computer-generated RTTY station: Note use of inexpensive black and white portable TV, SWTPC CT-64 video terminal, and home brew interfacing box.

What will you need to make use of this program? Basically, you'll need a KIM-1 interfaced to a moderate-speed video terminal. We use 1200 baud, but find that the receive program has to be slightly modified to allow it to operate at this slow speed. Higher speed terminals will require no modifications to the receive program. Of course, to use this program for transmit, any terminal will work regardless of how slow. As long as you're interfaced through the standard KIM-1 TTY pins, the speed of input won't matter. The program will simply convert the input ASCII to Baudot and output it at any desired speed. We've found, though, that, on receive, the terminal doesn't have time to output the decoded character and get back in time for the next start bit. WA5DXP mentions running his terminal at 4800 baud; we simply don't have anything that fast! At 1200 baud, we've found that simply removing the last JSR DEHALF (change his line 0267 to EA EA EA) will allow his receive program to work on slower terminals. Comments would be welcomed if you have other ideas.

You'll also need an AFSK to convert the output of the transmit program to the proper tones. The program defines a mark as pin PB7 high, a space as PB7 low. This TTL level output can be used to drive an AFSK directly. We use a couple of sections of a 7404 hex inverter as a buffer. If you have a reason to interface directly to a standard 60 mA loop, you might consider the optoisolator approach used in an earlier article on this subject (see the references at the end of this article).

The transmit program

R	2A	52	"	46	22			

Table 1. Code conversion. Note 1: "Figs" and "ltrs" were included in this chart so that you can manually produce them with an ASCII keyboard. The program produces them automatically whenever needed. They are included for testing only. Note 2: The "stop" or British pound symbol (depends on the receiving machine) can be sent by typing a "+" on your ASCII keyboard. Note 3: The "bell" can be sent by typing a "" on your ASCII keyboard. Other ASCII keys are "illegal" and will not produce a Baudot equivalent.*

deserves some comment on the methods used. After initialization of the ltrs/figs flag, the computer awaits input from an ASCII keyboard. Upon receiving that, it JSRs to a subroutine called STATUS where the incoming data is tested. If bit 6 is found to be a zero, the ASCII data was either a number or punctuation. In either case, the computer must check whether the last character sent was also in uppercase Baudot. If not, then the computer will have to send the figures command before it sends the character just input. If it determines that the last character was indeed uppercase, then all it needs to do is output the new character.

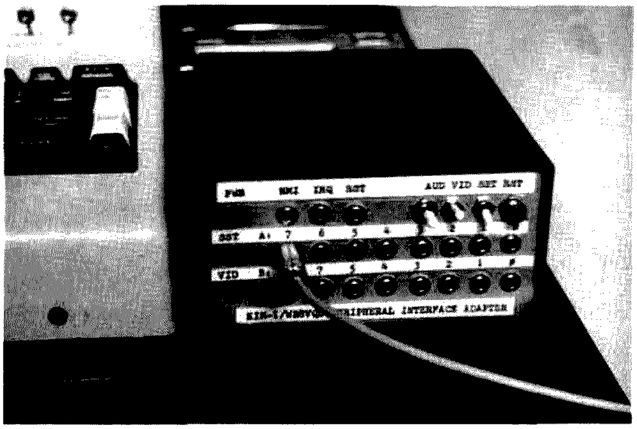
The same method holds true for lowercase, but in the reverse sense. The computer is initialized in the "ltrs" mode, since your first input will probably be a letter. Should you type a number or punctuation first, the computer will sense this and output a Baudot figures control and then your character.

Since we have chosen PB7 as the output pin for the transmit program, a 10k pull-up resistor will need to be added. PB7 on the KIM-1 has no internal pull-up (to permit collector-ORing with other devices). Simply connect a 10k ¼ W resistor from PB7 (A-15) and VCC (A-A).

Even before the computer has checked the status of the incoming character, it first rules out three special characters: space, line feed, and carriage return. A "space" produces the same effect as "unshift on space" in some mechanical printers. It's necessary as you're not going to have any idea of the kind of printer the other station will be using. If you type a string of numbers and then space to another string of numbers, the computer will shift down on the space and back up on the second string of numbers. The result to the user of this program or the station copying on the other end is insignificant. In other words, type whatever you want and you can be sure the other guy will copy regardless of the setup of his printer!

So why do we also disregard the line feed and carriage return as far as whether or not to send the figs/ltrs command? The main reason is that it simply does not matter whether a Baudot printer is in upper- or lowercase when either of these commands are sent. So the computer leaves you in the mode you are in.

After the status of the input character has been determined and figs/ltrs commands sent (if necessary), the character input is converted to Baudot, stored away, and then picked up by the XMT subroutine. Transmission of the resultant Baudot is accomplished in much the same manner as by a mechanical printer. The character is sent out, bit by bit, with a start bit (a space), five data bits, and a stop bit (a mark). The lengths of both the start and data bits are determined by the value loaded into the on-board KIM timer at location 03CD. Depending on the speed of transmission desired, load the value contained in Table 2. Likewise, since the stop bit is longer than a start/data bit, location 03E8 must have this delay constant loaded. The program is set for 60 wpm as written, since this is by far the most common speed for amateur RTTY trans-



Close-up of home brew interface box. Others might consider bringing all peripheral pins out to miniature phone jacks and all controls to outboard switches.

	60 wpm	66 wpm	75 wpm	100 wpm
Baud rate	45.5	50.0	56.9	74.2

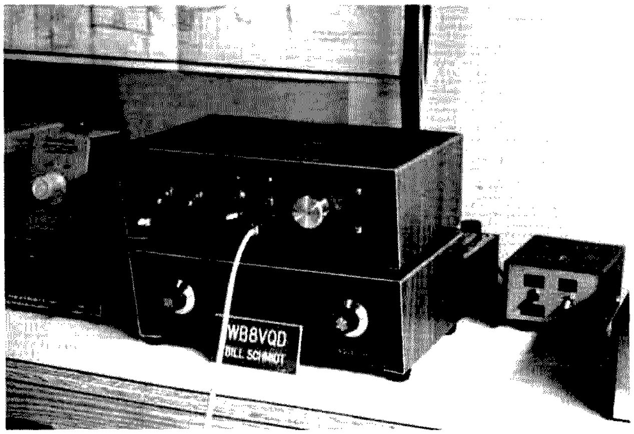
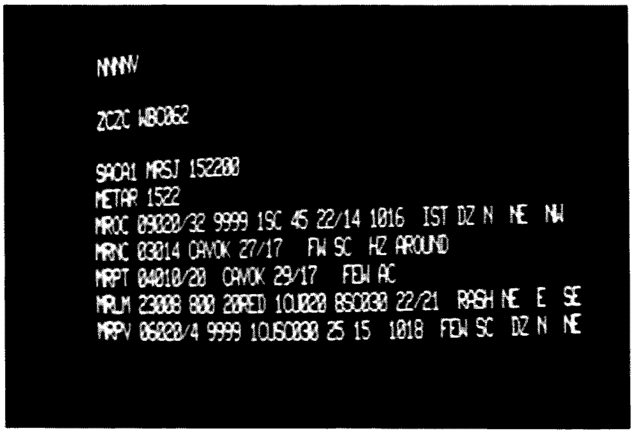
KIM total char. time (t = ms.)	159.74	153.60	135.17	99.33
Percent error (Allow ± 5%)	− 2.0	+ 2.4	+ 1.6	+ 0.3
Hex to load at 03CD	15	14	12	0D
Hex to load at 03E8	1E	1E	18	13

Table 2. RTTY timing table and delay constants. This table supplies data used by the RTTY transmit program. The values supplied for locations 03CD and 03E8 must be loaded if you want to transmit at a speed other than 60 wpm (the program is preset for this speed). Delay constants for receive are covered in WA5DXP's article.[1]

missions. Change the above locations only if you desire another speed. Upon transmission of the complete character, the program loops to the beginning where the next input is awaited.



Terminal unit provides both 60 mA loop for mechanical machine when we want hard copy and TTL level signals for the computer.



Example of weather broadcasts you'll be able to receive with the KIM. They are usually highly coded as this one is, but decoding manuals are available and we've found the NWS most helpful.

Note that, when you type a character requiring a shift, there is a quick two-step sound as first the command for figs/ltrs is sent and then the character, separated only by a stop bit. You'll probably get comments on this from people with mechanical printers, as they'll be used to "live" typing which won't usually produce this effect. Also, if you're a very fast typist, you may have to pause slightly since the computer won't be ready for your next character until it's completed the above operation. Normal typists and pick-and-punchers can disregard this warning!

The program does more than just allow real-time transmission of RTTY. It also incorporates a buffer so you can type a short message into the computer and have it output the entire message at full speed. This is accomplished in the BUFFR section of the program. Getting into this mode requires only that you type "Control B" (that is, push the control key down and hold it down while you type a letter "B"). You'll notice that further typing is no longer output to your AFSK. Instead, anything you type is stored away in memory for "full speed ahead" transmission. How do you know if the buffer becomes full? Every character you type will return with a bell sounding if you're using a mechanical ASCII printer or a tone if you're using an electronic terminal. The program is set up to allow about a three-line (at 64 characters per line) buffer. You can change this at location 0332. Whenever you're finished typing your message into the buffer, it can be sent by typing "Control T." Remember to turn on your AFSK and transmitter first, though! When your entire message has been sent, the program again loops to the beginning and awaits your next input.

You can also load your ID into a special ID buffer which is always ready to be sent when you type "Control I." See Table 3 for initial loading instructions. Since you'll certainly dump this program to audio tape, every time you load, your program and also your ID will be ready to go. You can use the ID as we do or make a slight change. Since we send the ID at the end of our transmissions, we have completion of the ID automatically jump us into the receive program. This is accomplished at line 0321. If you want to use this program without WA5DXP's receive program, then you'll need to change only this one line (see Table 4). This ID is in RTTY, so you'll need to either ID verbally or in Morse to satisfy FCC requirements.

A few notes should be made about the actual ASCII-to-Baudot code conversion table (see Table 1). This table takes into account all normal Baudot characters. Figs and ltrs commands are included for testing, but, since the

Step 1:	Decide what you want sent. Example: "DE WB8VQD c/r c/r l/f"		
Step 2:	Convert it to ASCII using the chart below:		

A-41	N-4E	1-31
B-42	O-4F	2-32
C-43	P-50	3-33
D-44	Q-51	4-34
E-45	R-52	5-35
F-46	S-53	6-36
G-47	T-54	7-37
H-48	U-55	8-38
I-49	V-56	9-39
J-4A	W-57	0-30
K-4B	X-58	space-20
L-4C	Y-59	c/r-0D
M-4D	Z-5A	l/f-0A

Step 3: Place your ID into memory beginning at 0100. Example:

0010	D	44
0011	E	45
0012	space	20
0013	W	57
0014	B	42
0015	8	38
0016	V	56
0017	Q	51
0018	D	44
0019	c/r	0D
001A	c/r	0D
001B	l/f	0A

Step 4: Tell the computer how long your ID is. This number, in hex, is loaded at 031E. If you're not familiar with hex, take the last location of your ID, add one, and use only the last digit. Example: My ID ends at 001B. If I add one, that's 001C. Using only the last digit, I get "0C" as the hex number to load at 031E. Disregard the number already at 031E.

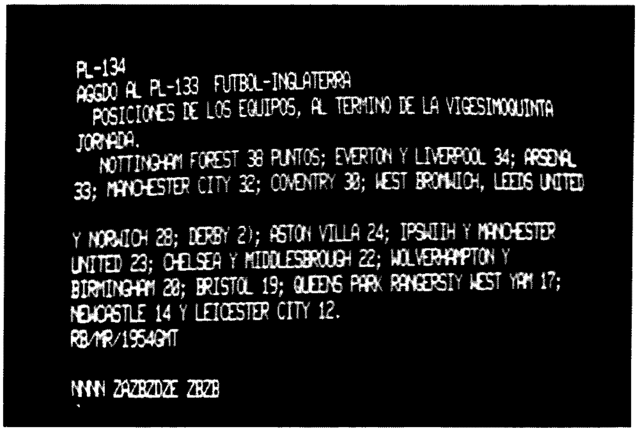
Table 3. How to load the ID with your call.

Change:

0249	4C	D0	02	JMP
024C	EA	EA		NOP
Add:				
02D0	2C	40	17	BIT SAD
02D3	30	03		BMI
02D5	4C	00	03	JMP Transmit
02D8	A9	80		LDAimm
02DA	2C	00	17	BIT PAD
02DD	4C	4E	02	JMP Back to Rcv.

Table 4. Changes to WA5DXP's program to adapt it to this transmit program to allow transceive. WA5DXP's program appears in the October, 1977, issue of 73 Magazine. The above changes allow switching back and forth from receive to transmit without manually resetting the computer each time (see the article for details). If you want this program for transmit only and do not want to incorporate WA5DXP's receive program into it, only one line needs to be changed:

0321 F0 E1 EA BEQ BEGIN (plus an NOP)



The computer won't mind foreign languages as this apparent sports broadcast proves. With the computer's ability to copy any speed, you'll be able to print much—but not all—of what you hear.

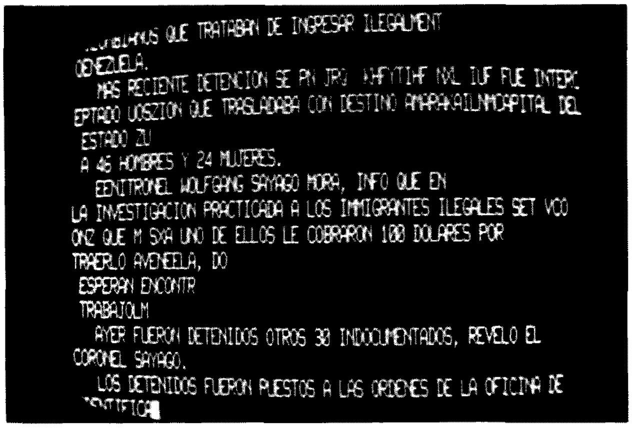
program supplies them automatically, you'll probably never use them. A Baudot "figs" is produced by typing "Control F" and a "ltrs" command by "Control L." If you are in the "ltrs" mode and type a "figs" command, you'll really get two of them, as the STATUS subroutine will supply one of its own! The same applies to typing the "ltrs" command when in the "figs" mode. Take this into account if you're inclined to experiment.

Delay constants for the transmit program appear in Table 2. Since only four speeds are legal on amateur bands, only constants for those are published. Percents of error are also included, as minor timing errors have not been corrected by the program. There's simply no need to, as any printer, mechanical or electronic, can handle errors up to 5%. Since we used the divide-by-1024 position of the KIM timer, even increments of milliseconds are not possible. Correction factors can be programmed in, but we found these constants plenty accurate for any use you'll probably ever encounter. One thing's for certain: A mechanical printer isn't going to care either way.

The receive program which we've referred to many times has performed well here for some time. We had considered writing one, but found this one to work so well we could see no sense in reinventing the wheel. We've copied everything from 60 to 100 wpm with no difficulty. If you're so inclined, the WX transmissions at 14.395 (LSB, 850 shift, 100 wpm) are a good deal of fun. Although the data is heavily coded, you'll see some plain English. This frequency is also one available quite near the top of a ham band and is accessible for those without a general-coverage receiver. You might also check out 7.405 (USB, 850 shift, usually 66 wpm) if you'd like to catch Spanish language telegrams. It's interesting and unusual to see the KIM decoding Spanish.

If you're in a QSO and want to get from receive back into transmit, type a space. At high speeds, the computer may not pick it up the first time. Try again. This is the sole purpose of the modification to WA5DXP's program appearing in Table 4. We didn't want to have to reset every time we wanted to send or receive. With this change, the computer is able to do all the work for you.

These programs have been used on the air in



News agencies, especially transmitting in Spanish, abound on the low bands. Copy is not perfect, but then we use a PLL-based TU and no filtering. A better TU should produce perfect copy!

numerous QSOs and have been found to create a quiet and efficient RTTY station. Aside from the advantage of saving the output from a mechanical printer, we're inclined to think this is the RTTY of the future—no noise, no oil. There's an obvious plus to being able to send and receive at any speed without changing gears. Changing speeds is as easy as typing in a couple of sets of numbers.

Comments are welcomed and inquiries will be answered if you'll include an SASE. Our thanks also to K8NLM who spent countless hours on the air helping with operational tests and to WB8ZVL whose suggestions led to many of the ideas incorporated into the program. ■

Keyboard Konvenience

—simplify entry of BASIC programs

Throw in an LED for good measure.

Rod Hallen WA7NEV
Road Runner Ranch
PO Box 73
Tombstone AZ 85638

I recently replaced my uppercase-only keyboard with one that generates both upper- and lowercase letters because word processing is one of my personal computing goals. However, this necessitates constantly shifting when entering BASIC and assembly language programs. The two circuits here (Figs. 1 and 2) allow either uppercase only or both upper- and lowercase operation at the flip of a switch. Numbers, punctuation, etc., are still under the control of the shift key. Both circuits are different methods of implementing the same function depending on what type of IC gates you have available.

The LED indicates upper- and lowercase operation, but it can be eliminated since the position of the switch or the operation of the keyboard will indicate which mode has been chosen. I just like lots of lights.■

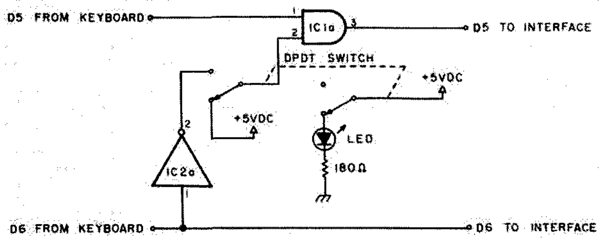

Fig. 1. IC1a = SN7408N AND gate. IC2a = SN7404N inverter. Pin 14 is + 5 V dc on both ICs and pin 7 is ground.

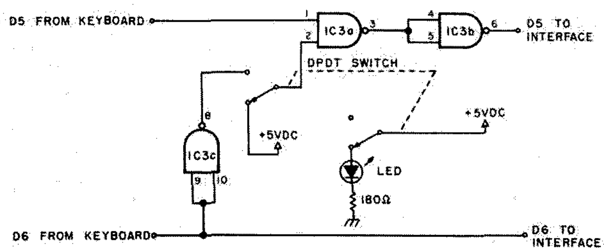

Fig. 2. IC3a, b, and c = SN7400N. Pin 14 is + 5 V dc and pin 7 is ground.

DXCC in One Sitting

DXCC PROGRAM - WRITTEN BY GARY TONCRE WA4FYZ
REVISED BY CHRIS WEINER N2CR  EX - WA2AYY.
QRZ?  >WA2GMO
```

Fig. 1. Program listing.

easy, but the award is commensurate with the effort put forth. So jump in with both feet and try your luck with Computer DXCC. If you don't want to use this program as is, read on. It is adaptable to many other uses.

The original program was adapted from a quiz program in *Basic Programming* by Kemeny and Kurtz. Over a period of some six months, we have updated the program again and again. Somehow, every time we work a new country, it ends up being in the program!

The Program

The program as listed gives complete instructions in the opening lines. Line 30 asks for your name or call, and it is stored as H$.

The program allows you to select a "class" of DXCC, which is determined by the number of countries that you play. The maximum is 50 countries for the Extra Class DXCC. The countries are arranged in the data statements in an increasing order of difficulty.

You automatically win if you answer 90% correct. Thus, if you answer correctly the first 45 out of the 50 Extra Class countries, the program will go directly to the certificate awarded to the winners.

If a country name is given, you must supply the prefix. If the prefix is given, then you must supply the name of the country as it appears on the ARRL DXCC Country List. You are given two chances to answer each question without penalty. The number that you answered correctly is considered worked and confirmed. Wrong answers are considered as worked only. The program keeps track of your worked/confirmed record, as well as a percentage computed from them. A certificate is awarded to those who make the grade.

Program Breakdown

Lines 10 to 150 supply information on how to play the game. Lines 160 to 440 set up the computer for the number of countries that you want to work (variable N in lines 380 to 440). Lines 500 and 510 set variables W (for your worked countries tally) and X (for those confirmed) equal to zero.

The main body of the program starts at line 520. The loop is completed at line 720 and is executed N times. Line 530 reads the first two pieces of data from line 880— in this case, "Guantanamo Bay" and "KG4." Notice that the data is set up to alternate the country's prefix and the country's name as the question.

Line 540 sets up variable T to keep track of whether your answer is the first or second try. Line 550 prints the country or prefix, and your answer is recorded in 560 as G$. If your answer is right, the program jumps to 650 and your worked and confirmed tallies are incremented by one each. The current record is

```
OK, WA2GMO.  THIS IS A GAME DESIGNED TO TEST YOUR
ABILITY TO IDENTIFY PREFIXES AND COUNTRIES THAT
MAY BE WORKED ALONG THE WAY TOWARD RECEIVING THE
AMERICAN RADIO RELAY LEAGUE'S DX CENTURY CLUB
AWARD.  YOU MAY SELECT THE CLASS OF DXCC THAT YOU
WANT TO TRY FOR ACCORDING TO THE FOLLOWING
NUMBERS OF COUNTRIES:

        NOVICE DXCC           15 COUNTRIES
        GENERAL DXCC          25 COUNTRIES
        ADVANCED DXCC         35 COUNTRIES
        EXTRA CLASS DXCC      50 COUNTRIES

THE NUMBER CONFIRMED IS THE NUMBER RIGHT.
DXCC WILL BE AWARDED FOR 90% CORRECT.
YOU WILL GET TWC CHANCES TO ANSWER CORRECTLY.

WHICH CLASS OF DXCC DO YOU WANT TO TRY FOR?
ENTER THE CLASS EXACTLY AS LISTED ABOVE?  >NOVICE DXCC

IF THE COUNTRY IS AN ISLAND, THEN THE WORD 'ISLAND' IS NOT IN THE NAME.
ALL COUNTRY NAMES ARE TAKEN FROM THE ARRL'S DXCC LIST.

73, WA2GMO
UNIVAC 1100 IS CLEAR AND QRT.
```

Fig. 2. Sample program run.

printed and the confirmed figure is compared to the 90% figure of the countries worked of your class. If they are equal, or if the confirmed figure is greater, a jump is made out of the loop at line 710 to line 760. Otherwise, the loop repeats.

Assuming that you answered wrong just once, line 580 sends you to line 480, which is printed. T is incremented by one and you go back to line 550. If you goof again, line 590 sends you to line 490, which is printed; L=2, so line 610 is skipped and the answer is printed via line 620. Line 630 increments only your worked tally. A jump is made to the print of-your record in line 680, and the rest proceeds as noted above.

If you haven't jumped out of the loop by the time you have gone through it N times, you haven't made 90% correct. In that case, the program goes to line 850 by way of 750 and ends at 9999. If you did win, the program goes through lines 800 to 840 and into the certificate subroutine. The program then returns to line 850 and ends at 9999.

Modifications

This program was written on a Univac 1100 at the University of Miami. It should run as is on most large college and high school computers. If you want to run it on your micro, some changes might have to be made in the interests of conserving memory. You can eliminate lines 10 to 260, but, if you eliminate H$ in line 40, it won't be there to print your name or call on the certificate in the subroutine. You could also decide on just one class and eliminate everything up to line 450, except for giving N some value equal to the number of countries in your list. You could also eliminate the subroutine, but the certificate is nice, especially if you can get a hard copy of it. Of course, you can change the data to any countries or prefixes that you want, except those beginning with a number such as 5Z4—variables like those won't be accepted by the computer. If you don't want to alternate country-prefix-country, you can set up the data to print either the country or the prefix alone as the question. You can also make the game easier to win by changing the winning percentage on line 700 and also the print statement on line 230.

One of the nicest features of the program is that, by changing the data statements, you can adapt DXCC into a quiz, such as naming the capitals of the states. Just rewrite the data lines to read state-capital-state-capital and so on. The number of different quizzes that can be derived from this format is endless.

Note that our Univac accepts line 1030, the command "page." This allows our printer to print the certificate on a separate page. You might have to make a loop of print statements if you want this feature but lack the page command.

Conclusions

We have spent many happy hours writing and playing DXCC. If you really want to get into it, try randomizing each class and making a large data list. We hope you enjoy DXCC, and, if you come up with any more modifications, send us a list of your version. We would like to see what you're doing. ■

Reader Service—see page 195

A Low-Cost Circuit Board Holder

—price tag: 45¢

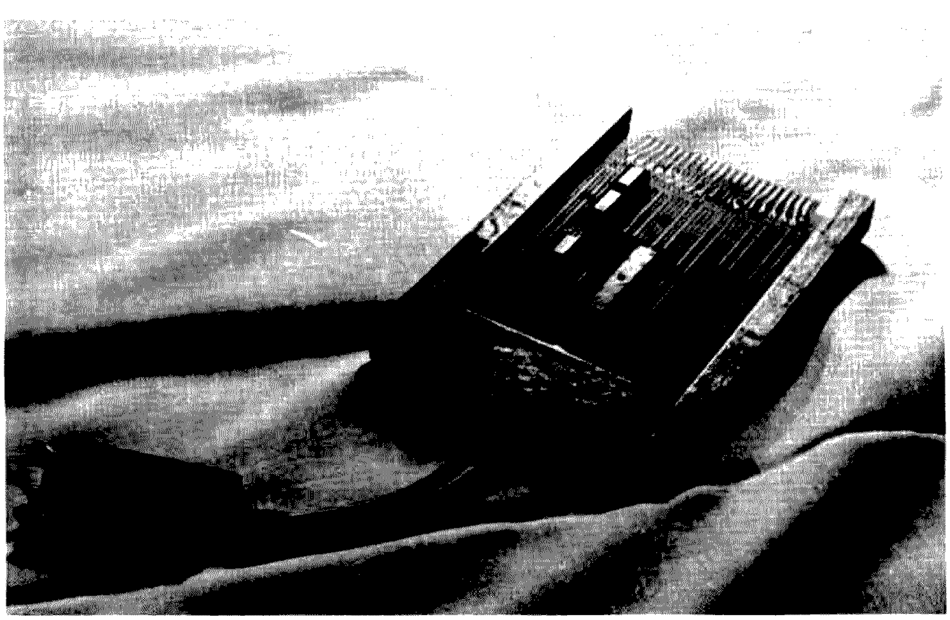
The stingy solution.

Russell W. Steele
838 Gayle St.
Papillion NE 68046

If you are still chasing PC cards across your workbench, you may be interested in a cheap card holder for PC boards. I was bitten by the computer bug this last winter and decided to build a system from scratch, using MSI and LSI chips and standard 44-pin prototyping boards. After evaluating a number of CPU chips and "one-board" systems, I decided to build a system based on the *Popular Electronics* ELF.

My goals were: to learn as much as possible, to keep the project within my limited budget, and to end up with an expandable system. The ELF was less than $100, and I felt it would be easy to expand with other hand-wired boards. I didn't feel competent to make my own PC boards, so I chose the prototype board and wiring-pencil method.

After collecting the necessary parts and designing a layout, my first problem was holding the PC board so that I could use a wiring pencil in one hand and a soldering iron in the other. My first thought was to locate a professional card holder and vise (such as the PANA-VISE), but it came down to a choice between using my limited cash for expensive equipment or buying computer hardware. I chose the latter, electing to solve the card-holding problem with my junk box and some leftover ingenuity.



A $.45 card holder.

After making sketches of my idea (Fig. 1), the next task was to collect parts. Rummaging among my bits of this and that stored in the garage, I spotted a hardwood stave from a shipping crate (2" x ¾" x 18") and a short length of threaded rod (¼" x 12"). In one coffee can I found five 1½" screws left over from a curtain-hanging project (I used molybolts after the curtain fell down), and in another coffee can were five washers and two wing nuts from a TV antenna that blew down long ago. It pays never to throw anything away!

That left me with some T-nuts to pick up at the local hardware (a package of five for 45¢). With this collection of bits and pieces, I hoped to make a PC card holder for a standard prototype board (4" x 6" or 4" x 9"). The size of the holder can be selected to suit your own needs. The small Radio Shack boards will fit if they are slipped in sideways.

To build the holder, I cut two pieces of hardwood

(½" x ¾" x 8") and then put a 1/16" kerf down the length of each piece. This kerf was to hold the card once the wooden fingers were securely fastened to the buttblock with the four 1½" screws. I cut the 1½" x ¾" x 4-3/8" buttblock from the remaining hardwood and beveled one end. The bevel allows adjustable tension for one finger, permitting a snug fit on a variety of similar-sized cards. (I find small variations in different manufacturers' cards.)

Before fastening the fingers, I drilled a 5/16" hole in the center of the block and two pilot holes for the screws at each end. Next, I turned the buttblock up so the narrow side faced me and drove a T-nut into the 5/16" hole.

I then selected a 2" x ¾" x 2" section of the remaining hardwood, drilled a 5/16" hole through the center, and drove a T-nut into the hole. I now had two blocks with T-nuts.

Next, I fastened the fingers on the 2" x 4-3/8" block, one to each end. I found it advisable to pre-drill the screw holes in both the buttblock and the fingers. I drilled the finger holes so they would just fit over the screws. This made the buttblock holes snug enough to keep a good grip on the screws.

I assembled the holder by threading a wing nut about three inches onto one end of the rod, with the wings toward the center. Then I put a washer on the rod and then threaded on the card holder. I then threaded the remaining block on the rod with the T-nut facing the wing nut. Twisting it until the end protruded below the end of the block, I slipped on a washer and a wing nut.

At this point I put the bottom block in the vise and bent the rod approximately 70°. In this position I can swing the holder in an arc or set it in position by tightening the wing nut at the bottom of the 2" x 2" block. I can position the holder at any 360° position on the end of the rod by tightening the wing nut behind the buttblock.

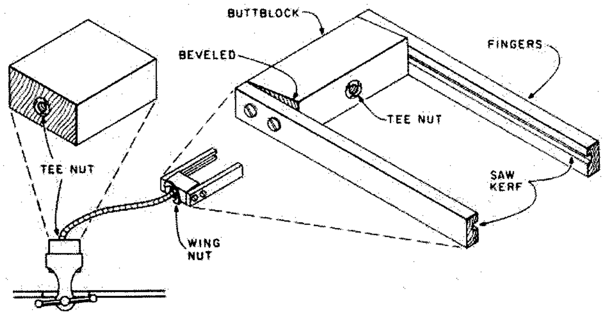


Fig. 1.

A coat of varnish finished the job. A PC card holder for less than 45¢! That is not counting the threaded rod (about $1.00) and the vise—which every hobbyist should have on hand.

In using the "cheap card holder," I find it useful to place a small mirror on the workbench under the PC card so that it is easy to see if wires pushed through from the other side are positioned correctly. It is not difficult, however, to flip the holder over to check wire position and flip it back again. I hope you find this as useful a tool as I do. ■

User Report: the IC-245

—good things come in small packages

Only two reservations.

R. Stanley Dicks W8YA
Box 331, RD2
Triadelphia WV 26059

As many amateurs now are doing, I recently decided to upgrade from a crystal-controlled two-meter rig to a synthesized transceiver. I wanted an all-mode rig, but one which also was compact enough to use on FM from my small foreign car. After surveying the current market, I decided to try the Icom IC-245 with sideband adapter, and I definitely have not been disappointed! The compactness of the rig is truly amazing: It contains a fully-synthesized two-meter FM transceiver, a digital display, and a sideband/CW adapter, all in a box not much bigger than most two-meter FM rigs alone. Crammed into this box are 47 transistors, 8 FETs, 24 ICs, and 61 diodes, and one heckuva two-meter rig!

The 245 is fully synthesized from 144 to 148 MHz. From 146 to 148 MHz, it tunes in 5-kHz steps, and from 144 to 146 MHz in 100-Hz steps. There is, however, a button which allows one to tune in 5-kHz steps below 146 MHz, making sweeps of the band more rapid. Tuning is accomplished with a single large knob, eliminating the two or three switches and knobs which often must be turned on other synthesized rigs. The knob has a solid feel and has a click-stop mechanism so that it clicks and holds firm at each increment. This prevents possible drift due to jostling in the mobile, and also allows for tuning in heavy traffic without having to look at the rig. If one is on .76, for example, one can go to .79 simply by counting six clicks on the dial (at 5 kHz each).

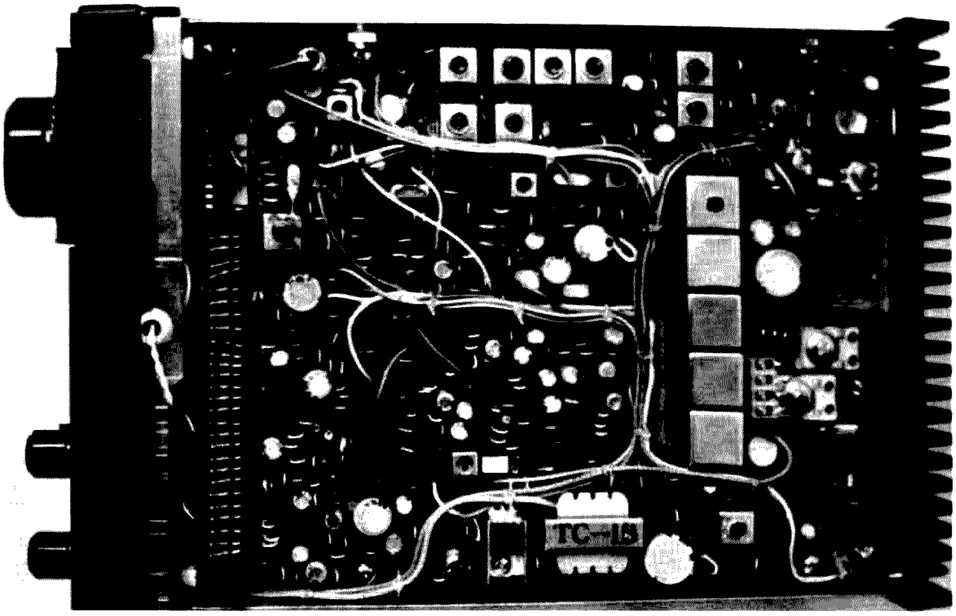
This is the Icom IC-245.

The rig comes with a quick-tuning adapter knob which easily can be slid onto the main knob, allowing rapid tuning across the band—especially on SSB. The digital display is large and easily readable, with four digits (146.52 reads out as 6.520), and an automatic dimmer so that the digits are dimmed in a dark environment (in the car at night) and bright in high ambient light. They shine brightly enough to read in all but very strong, direct sunlight. The meter indicates relative power on transmit and signal strength in receive.

The unit has an ingenious dual vfo system, also in use in Icom's 701 and 711, which allows almost total versatility in setting up offset frequencies. Under normal circumstances, one lines up the vfos 600 kHz apart, and they then track together for the routine repeater split. However, it is possible to program any split desired from 5 kHz to 955 kHz. The in-

 May 1979

struction manual says that the unit has an automatic reverse circuit so that when tuning from 146 to 147 MHz, the 600-kHz split will automatically reverse, making it unnecessary to throw a switch to reverse transmit/receive frequencies above 147 MHz. A note accompanying the manual, however, states that, "due to customer requests," this automatic reversal system has been defeated by the addition of a single shorting wire. The note says that the wire must not be removed while the rig is in warranty. As soon as my warranty expires, I intend to remove the wire and see what happens; if the reversal system functions, it would make repeater access possible anywhere from 146 to 148 MHz without the necessity of throwing a single switch. Nifty?



A bottom view of the IC-245 shows the five connected cans containing the helical resonators which are responsible for the rig's excellent selectivity. The final transistor is in back.

The 245 runs 10 Watts on FM (true FM) and CW and 10 Watts PEP on upper sideband. Local stations report that the audio is crisp and clean on both FM and SSB, and that the CW note is excellent, with no chirping or clicking. They also report that carrier suppression is excellent; even when I am over S9, no one can hear any carrier at all.

The receiver section of the rig has the quality for which Icom has become renowned. Even in the presence of strong local signals, I have never heard any cross modulation or front-end overload. The audio sounds sharp for a two-meter rig, and a rear panel jack allows plug-in of an external speaker. The receiver seems to be quite sensitive on both SSB and FM. An FM signal of S1 will be full-quieting, and sideband signals are regularly copied which are out of range of the rig's 10-Watt transmitter. In fact, the receiver's sensitivity causes some frustration; I hear many stations I can't reach with only 10 Watts!

On FM, the 245 has a conventional double-conversion system with i-f stages at 10.7 MHz and 455 kHz, and on SSB/CW it has a single-conversion i-f at 10.7 MHz. Sensitivity is rated at 0.5 uV for a 10-dB (S+N)/N ratio on SSB/CW, and 0.6 uV for 20 dB of quieting on FM. If anything, the rig appears to be more sensitive than its ratings. The noise blanker for SSB/CW reception is quite effective at cancelling the occasional hash-type noises I have tried it on, and the rig is considerably more impervious to auto ignition noise than was my previous rig. No matter what I did to try to suppress ignition noise with the old rig, I had about S4 QRN; with the 245, the ignition noise is barely discernible. The receiver has a switch to select a slow agc rate for SSB reception, and the result is SSB which sounds as smooth as low-band SSB on my Drake receiver.

One can cite features and specifications all day, but the proof, as they say, is in the punch. The 245 is a delightful rig to own and operate. It is compact and therefore easily transferred from auto to house and back. Recently, I stuck it in my suitcase along with a small 12-volt supply and a whip antenna and took it on a business trip. Try that with other multi-mode rigs! Two-meter SSB operation from the 14th floor of a hotel is fun!

At home, with an 11-element, vertically-polarized beam at 70 feet, I can hear literally hundreds of repeaters on the synthesized rig and can regularly call into machines as far out as 150 miles. This is one of the real joys in store for the crystal-controlled operator who changes to synthesization; the number of accessible repeaters is staggering. The vertically-polarized beam doesn't do well on SSB and CW where most other stations are using horizontal antennas, but even with cross-polarization, the Icom's 10 Watts and sensitive receiver provide regular contacts out to about 100 miles. The 245 gives one full flexibility on two meters: FM work on any repeater or simplex frequency, satellite work, weak signal CW and SSB DXing, mobile and portable work, and so on.

I can cite only two reservations about the 245. First, it operates only USB, and thus cannot be used for mode J OSCAR work on SSB; maybe Icom will come out with an LSB filter. Second, the photosensitive cell which controls the automatic LED readout dimmer is located right beside the tuning knob. This means that when the operator reaches up to tune the knob, often he blocks light from the cell, causing the readout to dim. It is only a minor nuisance, and one soon learns to move the hand slightly when tuning so that this doesn't happen.

These reservations are negligible when compared to the flexibility and performance which such a small package provides. I can hardly wait to get a horizontal beam up and a small linear amp to tack on to the rig, and I am working on OSCAR antennas now. See you on 144.200! ■

The History of Ham Radio

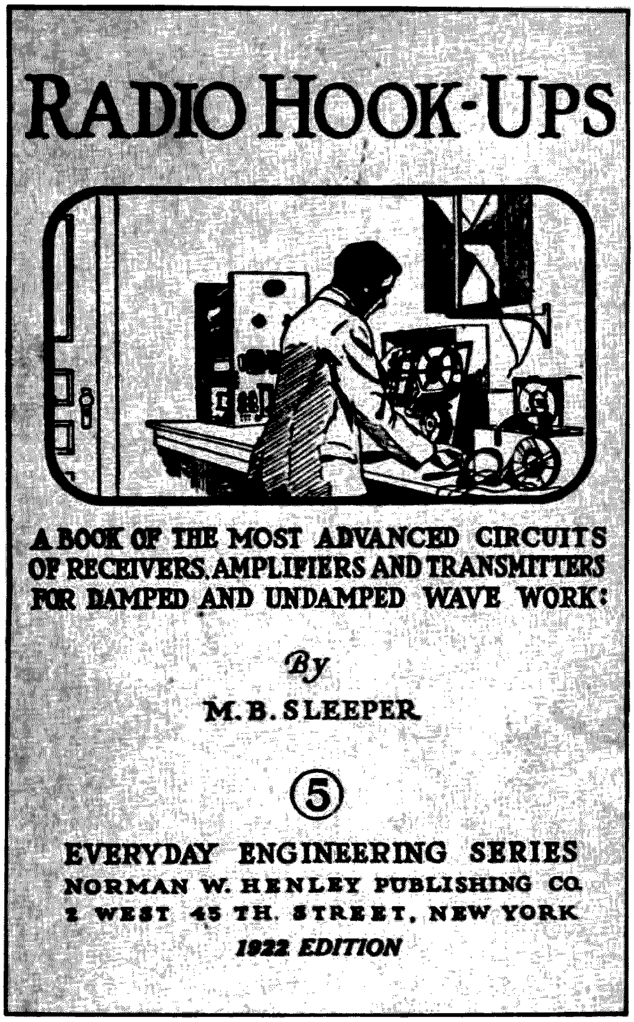
—part VIII

The early '20s.

Reprinted from QCC News, a publication of the Chicago Area Chapter of the QCWA.

The evolution of radio before, and to a great extent during, the 1918 war year was for the most part in the hands of radio amateurs and the experimenters. The development of the vacuum tube and its utilization required much time for laboratory research. The quenched-gap and crystal detector were still very much in use. Considerable effort was being put forth by commercial companies together with government engineers, notably the Navy, to develop reliable means of generating undamped waves along semi-mechanical electrical lines. The culmination of these efforts was the Alexanderson alternator, providing high frequency energy with power up to 200 kilowatts to satisfy navigational and overseas communication demands.

Following the evolution of radio art, two major patent-issuing corporations emerged in America, undertaking research toward larger and better vacuum tubes to replace the quenched-gap and the alternator. They were Radio Corporation of America, a group consisting of General Electric Company, Westinghouse Electric and Manufacturing Company, and American Telephone and Telegraph Company, which



pooled patent licenses, and then Hazeltine Corporation, an independent licensing holder. This was a time when many patent applications were flooding the patent office covering circuit designs, and many component parts were entering into the assembly of radio receivers and transmitters. The two companies acted initially as holders of patent rights and issued licenses. Many individuals and small organizations, doing private research, were filing patent applications on hundreds of ideas pertaining to radio, thus leaving the budding industry wide open to massive confusion. The license holders tried to meet this avalanche of new developments by issuing warnings to developers, inventors, and all those who were active in the field, including those who purchased radio parts from dealers and jobbers. The warnings read, "the assembly of a receiver is only for your own private, experimental use, which includes broadcast reception of music and entertainment, not for broadcast transmission and NOT FOR SALE." In other words, licenses had to be obtained first by dealers or jobbers, manufacturers, or assemblers to go into business. With such regulations, back-door trading became commonplace, and many instruments found outlets designed to circumvent the restrictions.

It was to be expected that to satisfy the demand of the listening public, there would be concerns engaged in building and assembling receivers. During this period, it was not possible to standardize any specific design because of the extremely high rate of turnovers and obsolescence. The radio amateur was busily building and assembling sets for his friends and neighbors, who reaped the benefits of his expertise in wireless.

The market mushroomed with the proliferation of broadcast transmitters throughout the United States and the rapidly increasing availability of radio receivers. Improvements in quality and reliability also contributed to lowered costs. Vacuum tubes were produced by the thousands, gradually improving their function but remaining far from being a uniform product. The UV-200 detector and the UV-201 amplifier were the mainstays. All others were either experimental or leftovers from previous designs.

The year 1921 saw a rapid growth of broadcast radio service. Electric manufacturing companies, universities, newspapers, and many individuals obtained permission from the Department of Commerce to become broadcasters. Radio amateurs had permission to transmit news, music, and items of interest over their stations. Broadcasting received the attention and guidance of various government departments. Interest in radio was universal.

This rapid expansion also had its reverse effects. Interest waned when disturbances occurred. The reason—general news and entertaining music was relegated to one wavelength, i.e., 360 meters. Official government stations broadcasting information, weather, and market news were on a wavelength of 485 meters. Not all stations held to these wave assignments accurately. Deviations gave some stations advantages over others. There was not enough room for all to communicate without excessive crossovers. The 1921-1922 receivers were not built to be selective or to avoid overlapping signals. Unless stations geographically close together decided by agreement to broadcast at different times of the day or were located some distances apart, the listener was denied satisfactory reception.

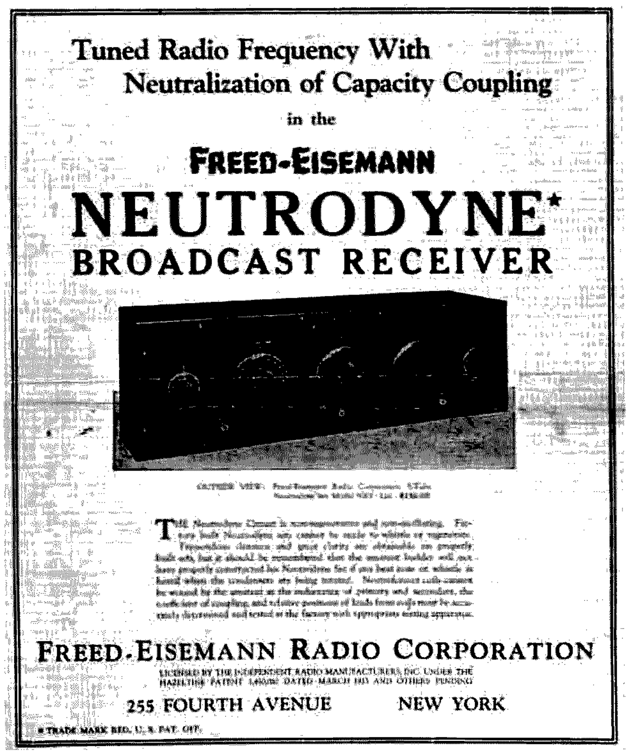
This troublesome problem of interference became so acute that in February, 1922, the Department of Commerce drew up plans which rearranged wavelengths to the broadcaster and to other services as follows:

Public Broadcasting, signifying broadcasting from universities, public institutions, and stations licensed for the purpose of dissemination of information and for educational services, was assigned 485 to 495 meters.

Private Broadcasting, signifying broadcasting by a newspaper, private or public organization, or person licensed for that purpose, including amateurs, was assigned 100 to 150 meters and 285 to 485 meters.

Other wavelengths were intended for commercial ship to shore and overseas communication.

General broadcasting stations were on wavelengths sufficiently different so as not to be heard when a receiving set was tuned to another station. This was to be determined by the broadcaster himself, using his own equipment. Amateurs were supposed to operate mostly late at night, using wavelengths below 275 meters. The early receivers had practically no selectivity. They were



very broad tuning, unstable, and consumed a great deal of energy, operating from dry cells and storage batteries. Radio receivers which could be operated from the standard 115-volt circuit had not yet arrived.

In 1914, Major Edwin H. Armstrong invented a radio receiver circuit known as the regenerative circuit. He obtained a patent from the government on October 6, 1914. This circuit described the use of the vacuum tube in a detector-oscillator combination. Vacuum tubes were at that time only in the experimental stage, crudely constructed, unreliable, and not readily available. Consequently, very little development took place before 1917 to test the unique application of the Armstrong circuit wireless signal reception.

The regenerative principle in the circuit is most simply described by stating that when energy is applied at the input terminals of a circuit connected to a vacuum tube in oscillation, the circuit presents either a more negative or a more positive reaction. The objectionable feature of a regenerative circuit was self-oscillation, which was uncontrollable in the hands of the average user. The whistles and howls coming from the loudspeaker or headphones were shocking and became unbearable.

Under such unstable conditions, the radio amateur came up with novel innovations, especially when tuning to continuous wave signals. When using his audiotron tube or his Marconi, De Forest, Donle, or Connecticut "vacuum bottle" for that critical adjustment to bring the reception under control, the presence of a magnet in the proper vicinity of the tube, held at certain angles to the bulb, would increase the intensity of the signal. Close adjusment of the magnet gave excellent results.

Early in August, 1919, the De Forest Company announced one of the first receivers for the monitoring of phone and/or continuous wave signals. It covered 160 to 450 meters and was designated the three-coil ultra-audion. It was designed as a shortwave regenerative instrument composed of a series of individually-wired sections and was hooked up as a composite assembly. Hardly a receiver for use by the general public.

Receivers could be assembled following the circuits illustrated in handbooks like the one issued by M. B. Sleeper entitled *Radio Hook-Ups*. The illustrations basically used a coil or two, a tuning condenser, and either a crystal or vacuum tube detector plus a pair of headphones. The tubes available were leftovers, designed during the war by French, German, English, and American laboratories.

They were not very reliable and rarely gave uniform results. It was not uncommon to find a backroom laboratory coming up with some exotic tube design. The intent was to try to improve such undesirable characteristics as excessive filament current drain, objectionable interelectrode capacitances, and short-lived filament emission.

The radio literature of the 1920s carried instructions on how to assemble receivers utilizing various types of coils (these included universal, honeycomb, unilateral, duolateral, bi- and multilattice), tuning condensers (of the straight line wavelength, straight line frequency, book-type design), variometers, and variocouplers tied to a vacuum tube or two in cascade.

In 1920, the radio amateur and the avid listener had available receivers manufactured under license. They were known as Grebe CR instruments. These receivers were not the type to place into the hands of the uninitiated. They were meant for the radio amateur and experimenter.

For shortwave reception, which included broadcast, the internal capacity of the tube proved a bar to any straightforward solution. Realizing that the vacuum tube was at the heart of the problem, Major Armstrong came up with a solution in the circuit principle named the heterodyne and superheterodyne. It is based on the mixing together of two frequencies in order to produce two frequencies which are equal to the sum and difference of the other two. In so doing, an intermediate frequency was produced which could be more effective and responsive to the characteristics of the available tube. The resultant amplification was a comparison of the voltage applied to a second detector in the circuit to that of the incoming terminal voltage.

A receiver built along these lines required a series of 6 to 8 tubes and gave excellent amplification. It required skilled manipulation of the controls, since adjustments had to be made at numerous positions to track the frequencies of the incoming signal. Sensitiveness of the superheterodyne receiver was proven by Paul Godley while at Androsen, Scotland, in December, 1920, when he logged numerous American stations during the transatlantic initial DX contest, related in part V of "The History of Ham Radio."

In analyzing the various circuit combinations of the heterodyne, it was found that the operation of the system proved a little too critical, especially since, to avoid interaction, individual tubes were required for detection and for rectification. As a

result, tuning became more complicated. Engineers remarked that if some way could be found for tuning adjustments to be set and sealed in the laboratory by skilled engineers leaving relatively simple adjustments to the operator, the receiver would be the ideal.

The main difficulty which had to be overcome was the instability from the combination of high amplifications desired. The solution hinged on overcoming the generated oscillations when the number of tubes of the 1921-1922 vintage were hooked to one another in cascade. Much effort was expended in designing intertube transformers of air-core, special iron-core, special couplings, and windings, to balance the impedances from stage to stage. Instability was the problem, again depending on the tubes available.

Well known, in 1922, was a receiver called the neutrodyne. It was designed around a non-regenerative and non-oscillating configuration. When properly constructed and assembled, the one thing this circuit did not do was emit objectionable whistles. The neutrodyne relied on straightforward cascade amplification of the incoming signal. It started with one or two stages of radio frequency amplification, then detection and reinforcement with one, two, or even three stages of audio frequency amplification. It was a popular receiver in its day. The set suffered from an undue amount of internal noise, generated and amplified due to mismatched component parts, internal tube disturbances, and lack of sufficient tuning controls to balance out the inherent design faults.

About this time in the era of wireless evolution, the amateur's thoughts were directed toward mobile and portable gear. ■

W2NSD/1
NEVER SAY DIE
editorial by Wayne Green

from page 4

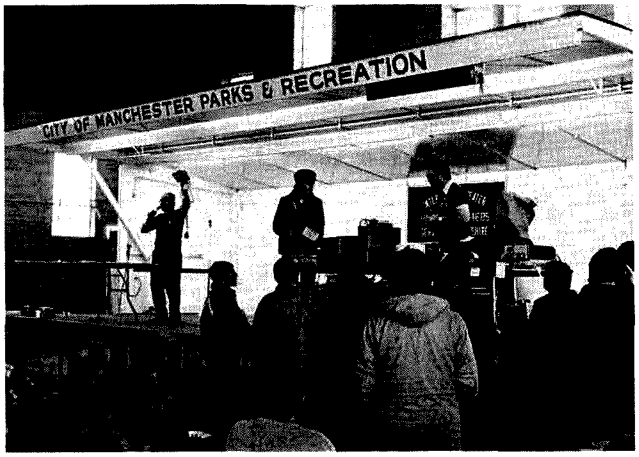
initials of that club) mounted their second annual auction in Manchester just before Lincoln's birthday. Chancy time of year for something like this, as they found out last year when Mother Nature dumped a bunch of snow on New England the day before the auction, effectively keeping most everyone home.

The crowd was excellent this year, and the Roving Camera was there to catch all the action. The auction brought out tons of vintage ham gear for a yearly change of ownership. I haven't seen so many Gonset Communicators all in one place in years . . . I wonder what the new owners *do* with them?

Manchester is only 35 miles from Peterborough, but then, New Hampshire is a very small state and most towns are not very far apart. Sherry and I often drive up to Manchester for a business lunch or dinner. The shopping is good there, too, particularly since there is no sales tax in New Hampshire. After visiting other states, it feels funny to buy things and pay only the price marked.

There is a particularly good

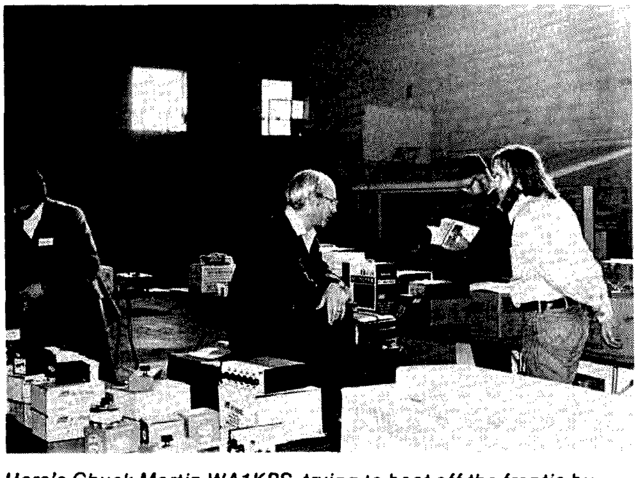
An excited mass of bidders, vying for every piece of gear, no matter how useless, is here letting its enthusiasm run away with itself over a particularly exotic rig.



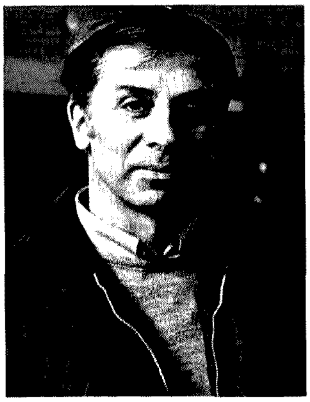
The auction is held in an armory in downtown Manchester, a cavernous place.

Much of the crowd wandered off to visit the tables of ham gear brought in by dealers such as Tufts Electronics, a carpetbagger from Massachusetts—a state known to most New Hampshire people for the tons of beer cans brought up by thousands of world-famous Massachusetts drivers and dumped alongside New Hampshire roads on weekends. Here is aging, paunchy Wayne in the center, listening to John Seeney of Cushcraft tell why his new magnetic-mount two meter antenna is selling so well. John had a display set up in one corner of the Tufts booth and kept a lot of hams enthralled with his hyperbole.

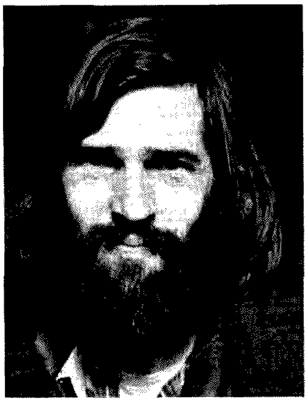
Jeff DeTray, the assistant editor and publisher of 73 *and* Kilobaud MICROCOMPUTING, *managed to contain himself through some of the more frantic bidding, returning with naught but pleasant memories of underbidding on equipment for which he would have no earthly use.*



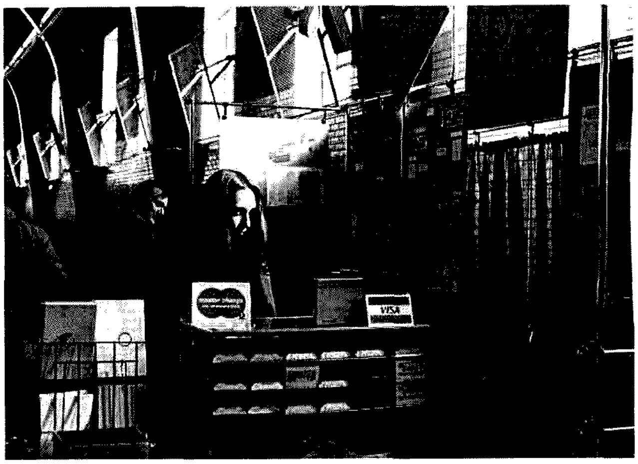
Here's Chuck Martin WA1KPS trying to beat off the frantic buyers of ham gear. Actually, I'm not kidding about the auction doing well for some of the commercial exhibits. Tufts did their best day of the entire month in sales as a result of the sales made this day . . . lots of 520s found happy homes. Chuck, who would much rather be skiing, gave in to commercial pressures and brought a truckload of stuff to New Hampshire, thus ensuring more healthy signals from this relatively rare state.



Over visiting, looking for microwave gear bargains, was Judson Snyder K2CBA, whom I've known for over 30 years. As a matter of fact, he used to bootleg with my ham rig before he got his own call. Jud is a big gun on UHF from the Troy area of New York.



This is Steve Murray K1KEC, who apparently lost his razor and scissors a few years ago. Steve is another skier, though he missed the yearly pilgrimage to Aspen this January. Steve has been deeply involved with repeater frequency coordination for about ten years.



A computer store from Boston had a display at the auction, attracting computerist Hal Chamberlin . . . one of the earliest publishers in the field. Hal put out The Computer Hobbyist *from North Carolina before wising up and moving to New Hampshire. His work with cassette systems lives on in many of the commercial systems today. Hal, by the way, was one of the first people I contacted when I thought up the idea for starting* Byte *magazine. He didn't seem to think that a magazine would do well for microcomputers, so I next tried Hal Singer, another editor of an excellent hobbyist newsletter. He didn't think much of the idea either, so I tried Bob Albrecht, etc., finally getting down to the chap I eventually picked, Helmers. I understand that Helmers has been sort of "retired" by* Byte, *so perhaps those who turned down the job made a better decision for the long run.*

supermarket in Manchester, too—Ferretti's—so I stopped by and found they had some fresh Chinese noodles! Now, how often do you see those in a supermarket? A few days later I got busy and made up a batch of spareribs with black bean sauce on soft noodles. This is a dish which I always get when I visit Hong Fat restaurant in Chinatown in New York (63 Mott Street). It's so good, you can become addicted to it. Imagine my surprise when I found that I could make it even better than Hong Fat! It's easy, once you figure out how to do it.

Not to turn *73* into a cookbook, but there are a few dishes which I've learned to make which are first rate, if you are adventurous in your eating. Oh, you're not? Okay . . . forget it.

SOFTWARE SURPRISE

One of the more pleasant surprises in the new software publishing business has been the sales of Instant Software's Ham Package I. This is a group of eight different programs for the Radio Shack TRS-80 microcomputer. These programs permit you to make most of the ordinary ham slide rule calculations quickly and easily—calculations such as Ohm's Law, frequency vs. reactance, series capacitances, parallel resistances, voltage dividers, etc. There are also programs which give you the dimensions for dipole and yagi antennas.

One of the more useful aspects of computerized calculations is the ability of the TRS-80 to draw the schematics of the circuits and antennas, complete with the dimensions.

With approximately 30% of the computer hobbyists also being radio amateurs, the sales of the Ham Package I programs were not expected to be low, but sales reports from Instant Software marketing show that this package of programs has consistently been one of the very best sellers. Only the Space Trek II and the Air Flight Simulator program packages have consistently been outselling the Ham Package! Space Trek II has been running about 40% ahead of the Ham Package, and Air Flight Simulator has been running about 15% ahead.

At $7.95 for the eight programs, the Ham Package has to be one of the better program values—and perhaps a harbinger of things to come as far as the publishing of programs in bulk is concerned. These are available from many of the computer stores, a few Radio Shack stores, and from Instant Software, Inc. A few ham stores are starting to set up computer program sales centers. Tufts Electronics is carrying the full line of Instant Software program packages.

JANUARY WINNER

John Murray W1BNN was the overwhelming winner in our January Most Popular Article contest. He will be receiving a $100 bonus check for his article, "SOS! Ship in Trouble!"

WE COOK, TOO!

On the left is Lynn Panciera-Fraser, the production manager for both 73 *and* MICROCOMPUTING *magazines. She's working with Sherry Smythe, our Executive Vice President, in making some Chinese steamed dumplings. I was not too busy making my spareribs with black bean sauce on soft Chinese noodles to snap this picture.*

Ham Help

I need a schematic and/or manual for a Sideband Engineers model SBE33. I will pay for photocopying and shipping.

Jeff Taylor W0NLU
R #1, Box 40A
St. James MO 65559

I need help with the digital multimeter article authored by WA4AIH in the April, 1978, issue of *73*. I need the source for the General Instruments AY-3-3550 IC and the Intersil ICL 8052 ACPD.

Social Events

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

SHREVEPORT LA
MAY 4-5

The Shreveport Amateur Radio Association will hold its annual hamfest on May 4-5, 1979, at the Louisiana State Fairgrounds. Pre-registration is $3.00; $4.00 at the door. This is an ARRL sanctioned hamfest.

NEENAH WI
MAY 5

The 3-F Amateur Radio Club will hold its annual swapfest on Saturday, May 5, 1979, from 8:00 am to 3:00 pm, at the Neenah Labor Temple, 157 S. Green Bay Road, Neenah, Wisconsin, just off Highway 41 at the Highway 114 or 150 exit. Facilities include a large parking area and a large indoor swap area with a free auction at the end of the day. Food and beverage will be available. Advance admission for tickets and tables is $1.50; $2.00 at the door. Talk-in on 52/52. For reservations, write to Mark Michel W9OP, 339 Naymut Street, Menasha WI 54952.

BINGHAMTON NY
MAY 5

The Southern Tier NY Amateur Radio Clubs will hold their 20th annual hamfest and dinner on May 5, 1979, at the Lutheran Fellowship Recreation Center, 3.7 miles north of NY Rte. 17, Exit 71 N., on Stella Ireland Road, Binghamton, New York. There will be technical talks, prizes, displays, exhibits, refreshments, and free flea-market parking. Tickets are $2.00 for general admission and $7.00 for the banquet (including general admission). Inside tables are $5.00 each, by reservation only. For tickets and information, write to STARC, PO Box 11, Endicott NY 13760.

DULUTH MN
MAY 5

The Arrowhead Radio Amateur Club will hold its annual swapfest on May 5, 1979, from 11:00 am to 3:00 pm at the First United Methodist Church, 230 E. Skyline Parkway, Duluth, Minnesota. Admission is $1.50 and tables are $1.50. Refreshments are available on the grounds. An auction will be held at 2:00 pm. Talk-in on .34/.94. For more information, write Harold Simmerman N9AMA, Swapfest Chairman, Route 1, Box 7, Lake Nebagamon WI 54849, or call (715)-374-3231.

DEKALB IL
MAY 6

The Kishwaukee Radio Club and the DeKalb County Amateur Repeater Club will hold their 21st annual indoor/outdoor hamfest on Sunday, May 6, 1979, from 8:00 am to 3:00 pm at the Notre Dame School, 3 miles south of DeKalb between Highway 23 and South 1st St. on Gurler Rd., DeKalb, Illinois. Tickets are $1.50 in advance; $2.00 at the door. Indoor tables are available or you may bring your own. The outdoor setup is free. Talk-in on 146.13/.73 and 94. For tickets and directions, send an SASE to Howard Newquist WA9TXW, PO Box 349, Sycamore IL 60178.

LOGANSPORT IN
MAY 6

The Cass County Amateur Radio Club will hold its second annual hamfest on Sunday, May 6, 1979, from 7:00 am to 4:00 pm at the 4-H fairgrounds, Logansport, Indiana. Go north of Logansport on Highway 25, turn right at Road 100, and follow the QSY signs. Admission is $1.50 in advance and $2.00 at the gate. Outside setup is free and undercover setup is $1.00. Bring your own tables. There will be overnight camping, refreshments, ladies' bingo, and door prizes. Talk-in on 146.52 and Logansport repeater 147.78/.18. For information, write Dave Rothermel K9DVL, RFD 4, Box 146G, Logansport IN 46947.

WARMINSTER PA
MAY 6

The Warminster Amateur Radio Club will hold its fifth annual "Ham-Mart" flea market and auction on Sunday, May 6, 1979, from 9:00 am until 4:00 pm, at the William Tennent Intermediate High School, Street Road (Route 132), two miles east of York Road (Route 263), Warminster, Bucks County, Pennsylvania. A registration fee of $1.00 per car includes one ticket for door prizes. Tailgating is $2.00 additional. Indoor tables are available for $3.00 each. Talk-in on 146.16/76 and 146.52. For further information, please write Horace Carter K3KT, 38 Hickory Lane, Doylestown PA 18901, or phone (215)-345-6816.

SACRAMENTO CA
MAY 6

The North Hills Radio Club, Inc., of the greater Sacramento area, is having their 7th annual Ham Swap on Sunday, May 6, 1979, from 9:00 am until 3:00 pm at the Machinists Hall, 3081 Sunrise Blvd., Rancho Cordova, California. Take Hwy. 50 to Sunrise, turn left, and go to the signs. For information, write Cecilia Pringle WB6PBS, Publicity Chairman, North Hills Radio Club, PO Box 701, Fair Oaks CA 95628.

ELLICOTT CITY MD
MAY 6

The Potomac Area VHF Society will hold its eighth annual hamfest on Sunday, May 6, 1979, from 8:00 am to 5:00 pm at the Howard County Fairgrounds, approximately 15 miles west of Baltimore, at the intersection of I-70 and Rte. 32, Ellicott City, Maryland. A registration fee of $3.00 includes flea market or tailgate sales. Professional food and beverage catering and unlimited parking will be available. Talk-in on .52. For further information, contact Paul H. Rose WA3NZL, 25116 Oak Dr., Damascus MD 20750.

IRVINGTON NJ
MAY 6

The Irvington Radio Amateur Club will hold its annual hamfest on May 6, 1979, from 9:00 am to 4:00 pm at the PAL Building, 285 Union Ave., Irvington, New Jersey. Take the Garden State Parkway to Exit 143 north or 143A south. There will be refreshments and prizes. Tables are $3.00. Talk-in on .34/.94 and .52. For information, contact Ed Surmaitis WA2MYZ at (201)-687-3240 evenings, or write to Irvington Radio Amateur Club, 285 Union Ave., Irvington NJ 07111.

FRESNO CA
MAY 11-13

The 37th annual Fresno Hamfest will be held on May 11-13, 1979, at the Sheraton Inn, Clinton and Highway 99, Fresno, California. The program includes technical talks, swap tables and flea market, transmitter hunt on 2 meters (146.52), QLF contest, ARRL CD appointees meeting, ARRL-FCC forum, commercial exhibits, prizes, eyeball QSOs, prime rib banquet, and more. For full registration and eligibility for pre-registration prize, send in $17 before April 27, 1979; it's $19 and no pre-registration prize after that date. Talk-in on 146.34/146.94. For more information, contact the Fresno Amateur Radio Club, Inc., PO Box 783, Dept. HF, Fresno CA 93712.

DEERFIELD NH
MAY 12

The Hosstraders Net will hold its 6th annual tailgate swapfest on Saturday, May 12, 1979, at the Deerfield Fairgrounds, Deerfield, New Hampshire. There will be covered buildings, in case of rain. Admission is $1.00, with no commission or percentage. Commercial dealers are welcome at the same rate. Excess revenues will benefit the Boston Burns Unit of the Shriners' Hospital for Crippled Children. Last year we donated over $1100.00. Talk-in on .52 and 146.40-147.00. For more information, send an SASE to Joe DeMaso K1ROG, Star Route, Box 56, Bucksport ME 04416, or Norm Blake WA1IVB, PO Box 32, Cornish ME 04020, or check the Hosstraders Net on Sundays at 4:00 pm on 3940 kHz.

VANCOUVER WA
MAY 12-13

The Fort Vancouver Hamfair will be held on Saturday and Sunday, May 12-13, 1979, at Clark County Fairgrounds, Vancouver, Washington. Registration is $4.00 per person, which includes a drawing ticket. Tickets are also available at the door. Activities will include contests, seminars, commercial and amateur displays, family events and a large ham radio flea market. Many prizes will be awarded, with the grand prize being an Icom IC-701 HF transceiver and power supply. The fairground facilities include trailer parking and ample car parking. A catered buffet dinner is scheduled for Saturday night, with musical entertainment included. Price of the dinner ticket is $5.00 for adults. For registration, contact Ken Westby W7DYX, Registration Chairman, 606 Miami Court, Vancouver WA 98664.

DAYTONA BEACH FL
MAY 12-13

The Daytona Beach Amateur Radio Association, Inc., will hold its first hamfest on May 12-13, 1979, at the Holiday Inn Surfside, Daytona Beach, Florida. For Mom and the kids, there is the "drive-on" ocean beach, and shopping in the oceanside plaza. Advance registration is $3.00 per family and $3.50 at the door. For more details, contact Funfest chairman David Rusler WA4ZTT, 1725 Hope Drive, Ormond Beach FL 32074.

SALINE MI
MAY 13

The ARROW Repeater Association will hold its annual Swap and Shop on Sunday, May 13, 1979, at the Saline,

Michigan, fairgrounds. Admission, including parking on the fairgrounds, is $1.50 in advance and $2.00 at the door. There will be food, prizes, and a covered area for trunk sales, as well as indoor tables. Because of Mother's Day, wives will be given free admission. Talk-in on 146.37/97, 223.18/224.78, and 448.5/443.5 MHz. For additional details, write ARROW, PO Box 1572, Ann Arbor MI 48106, or call George Raub AD8X at (313)-485-3562.

WAUKESHA WI
MAY 13

The Milwaukee UHF Society, Inc., will hold its second annual Spring Swapfest on Sunday, May 13, 1979, starting at 7:00 am on the grounds of the Waukesha County Exposition Center, Waukesha, Wisconsin. There will be prizes and refreshments. Admission is $1.50 in advance and $2.00 at the gate. Some indoor space is available. Dealers and exhibitors are welcome. For information, write Swapfest, Box 49, North Prairie WI 53153. Please include an SASE.

CADILLAC MI
MAY 19

The Wexaukee ARA will hold its 19th annual swap and shop on Saturday, May 19, 1979, from 9:00 am until 4:00 pm at the National Guard Armory, 415 Haynes Street, Cadillac, Michigan. Tickets are $2.00. There will be free parking and lunches available. Talk-in on 146.37/.97. For more information, contact Robert Bednarick WD8RZL, Publicity Director, Wexaukee ARA, Cadillac MI 49601.

BENSENVILLE IL
MAY 19

The Radio Amateur Megacycle Society will hold its third Antenna Measuring Contest on Saturday, May 19, 1979, starting at 10:00 am on the grounds of the Flick-Reedy Corporation, corner of Thorndale and York Roads, Bensenville, Illinois. Equipment will be available to measure the gain and swr of 2 meter, 1¼ meter, and 70 cm antennas. Equipment for higher frequencies will be brought if advance request is made. Prizes will be awarded for the highest-gain antenna in each category. Refreshments will also be sold. For further details, including directions, write Joe LeKostaj WB9GOJ, 2558 N. McVicker Ave., Chicago IL 60639. Please enclose an SASE.

BIRMINGHAM AL
MAY 19-20

The Birmingham Amateur Radio Club, Inc., will hold its Birminghamfest '79 and Alabama State Convention on May 19-20, 1979, at the Birmingham-Jefferson Civic Center Exhibition Hall, Interstate 20/59 at 22nd Street north (downtown Birmingham, 3 minutes from the airport). There will be air-conditioned exhibit space and an indoor air-conditioned flea market. Tentative forums are planned on a wide range of topics, from ARRL to microprocessors. Meetings will include MARS, ARRL, Alabama section nets/ARPSC, and others. On-site FCC exams will be administered on Saturday morning. Prizes include a Drake TR/DR-7 solid-state transceiver, a Kenwood TS-820, and a Drake UV-3 (complete). There will be a banquet on Saturday night at the Exhibition Hall, with special guest entertainer Jerry Clower. Family activities include games, movies, and bus tours of area sights. For information, contact Birminghamfest '79, PO Box 603, Birmingham AL 35201.

DURHAM NC
MAY 19-20

The Durham F.M. Association will hold its annual Durhamfest on Saturday and Sunday, May 19-20, 1979, at the South Square Mall, Durham, North Carolina. Plenty of prizes, exhibits, and programs will be offered, and the XYLs can enjoy shopping. Ladies' bingo will be held on Sunday. Free tailgating spaces, under a covered, drive-in-and-sell flea market, come with a one-time $3.00 general registration ticket, with vendors and dealers included. Electrical power will be available. Harmonics and unlicensed XYLs are admitted free. Talk-in on 147.825-.225, 146.34-.94, 222.34-3.94. For more information, write DFMA, Box 8651, Durham NC 27707.

BURLINGTON KY
MAY 20

The Kentucky Ham-O-Rama will be held on May 20, 1979, at the Boone County Fairgrounds, Burlington, Kentucky. For easy access, take the Burlington exit off I-75 south. JUL 27-29

The Moose Jaw Amateur Radio Club will hold its 1979 Hamfest (Particifest 79) on July 27-29, 1979, at the Saskatchewan Technical institute, 600 Saskatchewan St. W., Moose Jaw, Saskatchewan, Canada. Registration will be held on Friday evening with a full day of activities on Saturday culminating in a banquet and dance. Most of the meetings and workshops will be held on Sunday. There will also be a busy schedule for the XYLs.

OLIVER BC CAN
JUL 28-29

The Okanagan International Hamfest will be held on July 28-29, 1979, at Gallagher Lake KOA Kampsite, 8 miles north of Oliver, B.C., Canada. Registration starts at 9:00 am Saturday. Activities start at 1:00 pm Saturday and continue until 2:00 pm Sunday. Ladies may bring their hobbies and items for a white-elephant sale. Featured will be prizes, a flea market, bunny hunts, entertainment, a home-brew contest, and more. A potluck lunch will be served Sunday at noon. Call-in on 3800, .34/.94, and .76 simplex. For information, write John Juui-Andersen VE7DTX, 8802 Lakeview Dr., Vernon, B.C., Canada V1B 1W3, or Lota Harvey VE7DKL, 584 Heather Rd., Penticton, B.C., Canada V2A 1W8.

BOWLING GREEN OH
JUL 29

The Wood County Amateur Radio Club will hold its 15th annual Wood County Ham-a-Rama on July 29, 1979, at the Bowling Green Fairgrounds, Bowling Green, Ohio. Gates will open at 10:00 am, with free admission and parking. Dealer tables and space are available. Trunk sale space and food will also be available. Tickets are $1.50 in advance and $2.00 at the door. Prizes will be awarded. Talk-in on .52 K8TIH. For information, write Wood County ARC, c/o Eric Willman, 14118 Bishop Road, Bowling Green OH 43402.

JACKSONVILLE FL
AUG 4-5

The Jacksonville Hamfest Association is pleased to announce the 1979 Jacksonville Hamfest and ARRL North Florida Section Convention to be held on August 4-5, 1979, at the Jacksonville Beach Municipal Auditorium, Jacksonville, Florida. The location is just one block from the beach, where U.S. 90 meets the sea.

Advanced registrations are available at $3.00 per person from R. J. Cutting W2KGI/4, 303 10th St., Atlantic Beach, Florida

Improving the Sabtronics 2000

—make a good DMM even better

Easier maintenance is a bonus.

James D. Powell II N8AMR/4
6400 J Terrace View
Blacksburg VA 24060

Shortly after the ad for the Sabtronics Model 2000 digital multimeter appeared in *73 Magazine*, I sent in my check for one. I suspect that quite a large number of other people did the same, since my order was delayed several weeks. When the DMM finally arrived, I assembled the kit and, to my surprise, it worked the first time I turned it on. After calibration, using the supplied resistors as references, the meter's performance compared quite favorably to that of a more expensive DMM.

I was pleased with the meter for its performance, and pleased with myself for taking advantage of a good deal, until I noticed the meter would not zero on the ac scales. With the input leads shorted, the display would eventually settle down at about 0.5 volts on the 10.0-volt scale. A quick check showed that all of the ac voltage and current scales were affected.

At first I assumed that I had made some mistake in construction, but checking with two other owners of the Model 2000, I found that they noticed the same problem.

Fortunately, the design error is easy to correct. I will describe the necessary modification, plus a relocation of the fuse holder and installation of nicad batteries and a charger for convenience.

After I studied the board layout and schematic for the DMM, I tried a few things that looked as if they might correct the trouble. I found that if I unhooked the +6 volts that powered the decimal points, the meter would zero properly. Apparently, the high level dc line that feeds the decimal points is located too near the low level ac lines on the main PC board. You can see there is quite a mess of traces carrying the various signals to the range and function switches if you check the layout diagrams in the manual.

Before I describe the modifications I made to the circuitry, I want to say that I have had no contact with Sabtronics on this matter. I hope they corrected the problem in later model runs, but I do not know. Obviously, you can check to see if your meter has the problem by simply

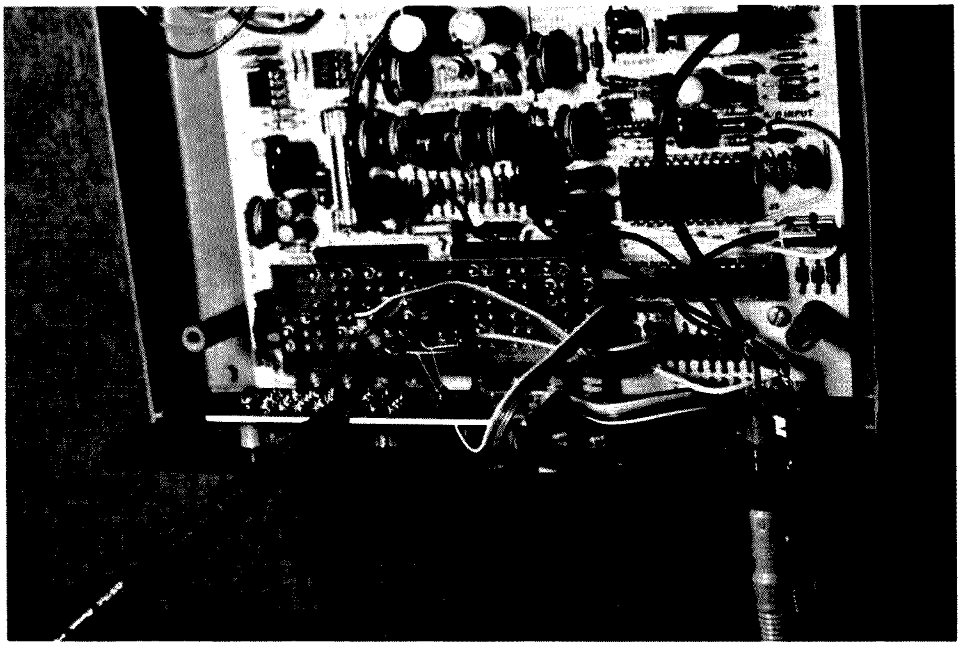

Photo 1. This is the display board of the Model 2000 DMM, showing the added transistors that drive the decimal points.

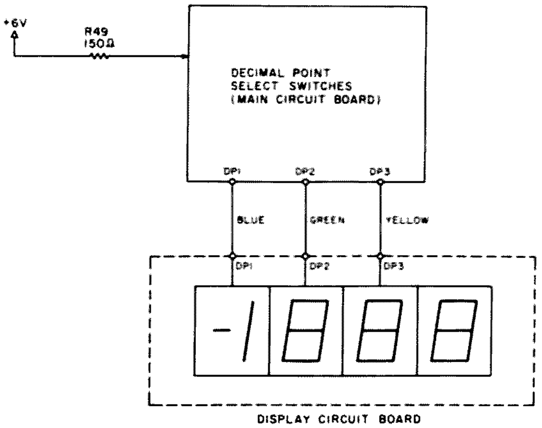

Fig. 1(a). Block diagram of decimal point driver circuitry of the Model 2000 DMM before modification.

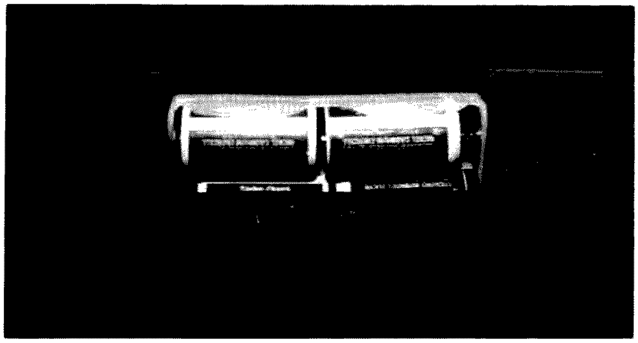

Photo 2. This pictures the rear of the DMM, showing the added fuse holder on the right and the charging jack and components on the left.

shorting the input leads and punching up the 10.0-volt ac range.

If you refer to Fig. 1(a) and compare the simplified diagram with the schematic in your manual, you will see that the range and function switches drive the decimal points directly off the +6.0-volt line through R49 (150 Ohms). Fig. 1(b) shows a block diagram of the circuit after modification. The modification requires only three garden-variety PNP transistors and three ½- or ¼-Watt resistors. You do not have to cut or modify any of the traces on the PC boards.

Fig. 2 shows the actual schematic of the added circuitry. The transistors drive the decimal points; the switching arrangement on the DMM main PC board is now near ground potential and carries only the small base current needed to drive the transistors. Although a small PC board would have allowed a neat installation, I did not think it was necessary for so few parts. In the following steps, refer to the diagrams of the PC boards in your Sabtronics manual as well as to the diagrams and photographs I have supplied.

Photo 1 shows how the transistors are mounted on the display board. First, unsolder the end of R49 that is nearest the edge of the main PC board. Bend this resistor straight up so that it is perpendicular to the board. Solder a short length of hookup wire from the hole where you just removed R49 to the ground lug on the input terminals of the front panel. Now remove the three wires on the display board marked DP1, DP2, and DP3. You can do this without removing the board if you are careful. Prepare the three driver transistors by bending the base lead of each one back over the case so that it is parallel to the other leads but pointing in the opposite direction. Solder one of the resistors to each base lead. I used 10k-Ohm resistors with the junk box transistors I had, but you may need to use smaller values (on the order of 2k) with some transistors.

Working on the back (side of the board with traces) of the display board, solder the collector lead of one of the prepared transistors in the hole marked DP1 where you re-

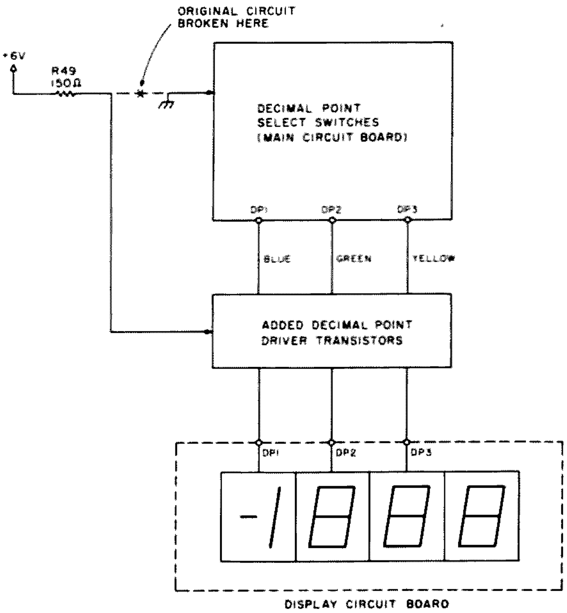

Fig. 1(b). Block diagram of the decimal point driver circuitry of the Model 2000 DMM after modification.

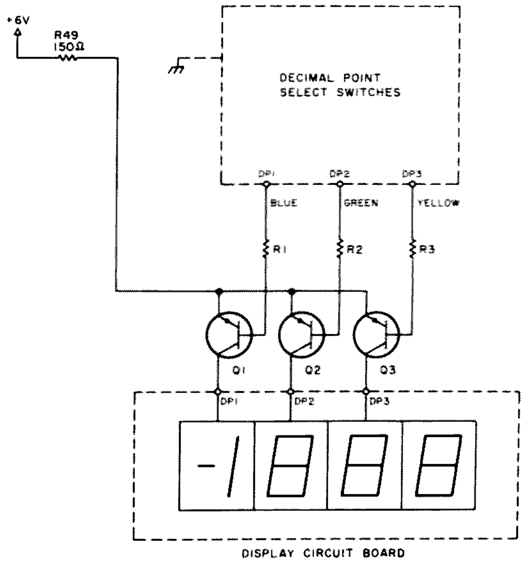

Fig. 2. Schematic of decimal point driver circuitry. R49 is part of the original DMM circuit. The transistors are added to the back of the display PC board. R1, R2, R3: 2.2-10kΩ (see text), ¼ to ½ Watt. Q1, Q2, Q3: any silicon PNP general purpose transistor, such as Radio Shack 276-1604.

moved the wire previously. Install the other two transistors in the holes marked DP2 and DP3. Solder the emitter leads of all three transistors together and attach a wire from the emitter leads to the free end of R49 on the main PC board. Finally, solder the free ends of the wires you removed from the display board to the corresponding resistor on the driver transistors you installed. This completes the decimal point modification and the meter should zero properly on all the ac scales after a few seconds. After you are sure everything is working properly, you may want to insulate the transistors with some silicone rubber or tape.

The second modification to the Model 2000 was simply the moving of the fuse holder. I manage to blow the fuse in my DMM about once a month by punching the current button with the leads connected to a battery. Since the fuse is mounted inside the Sabtronics meter, changing it requires that the case be disassembled. Unfortunately, I could not train myself not to blow the fuse, so I did the next best thing—I mounted a panel-type fuse holder on the right rear of the meter (Photo 2). I chose a Radio Shack (270-365) fuse holder since it extends only 0.5 cm on the back of the panel. If you install a fuse holder, short out the old one on the PC board. A short piece of a potentiometer shaft works very nicely for this. You must use shielded cable running to the fuse holder since the power supply of the meter generates considerable noise and the longer input lead will pick this up.

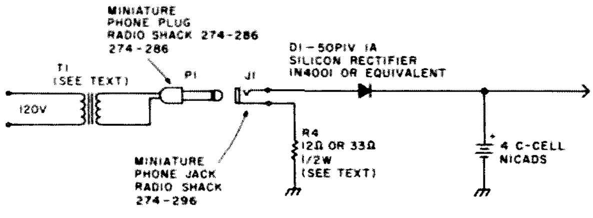

Fig. 3. Charging circuit for nicad batteries installed in the Model 2000 DMM. Adjust R4 for 100-mA charging current.

The last thing I did to the DMM was install rechargeable batteries. If you use your meter very much, you will find that replacing batteries is not only a nuisance but also expensive. I used some surplus nicad C cells that I ordered for $1.50 each. In order to charge the batteries without opening the case, I installed a miniature phone jack in the other panel on the rear of the meter (see Photo 2). For charging, I used one of the little transformers with which the phone company powers the dial lamps in some phones. The simple charging circuit is shown in Fig. 3. If you have one of these transformers (who doesn't?), a 12-Ohm, ½-Watt resistor for R4 will give the proper charge current for 1-Ah cells. If you don't have a transformer, a Radio Shack 12.6-volt transformer (273-1385) will give the proper 100-mA current with a 33-Ohm, ½-Watt resistor. Do not try to measure the charge current with the batteries installed in the meter unless you use another meter.

If you make these modifications to your DMM, you will have improved performance on the ac scales and the unit will be easier to maintain. I will be glad to answer any questions accompanied by an SASE.■

Turn Signal Timeout

—eliminates two-wheeled embarrassment

Thirty seconds is the limit.

Howard R. Worthington K1OTW
17 Fremont St.
Oxford MA 01540

Is there a motorcyclist who has not felt dumb and hazardous after discovering that he has had his turn signals on for five minutes after making a turn? Here's a simple circuit to time them out in thirty seconds, if you forget. A few new bikes have a similar device; some riders install an audible indicator—but this is not dignified, honking away.

The 555 is used as a standard monostable timer from the *Motorola Linear I.C. Data Book*. Refer to the schematic. When the turn signal switch is turned on, pins 2 and 4 go high, which starts the timer and begins to charge C2. Pin 3 is high, keeping the relay off. When C2 is charged to 2/3 Vcc—thirty seconds in this case—pin 3 goes low and sinks the relay coil which opens the turn signal circuit. When the turn signal switch is turned off, pins 2 and 4 go low, which resets the 555; at this time Q1 turns off and prevents C2 from being charged, so you will have a full 30 seconds of flashing time at the next intersection.

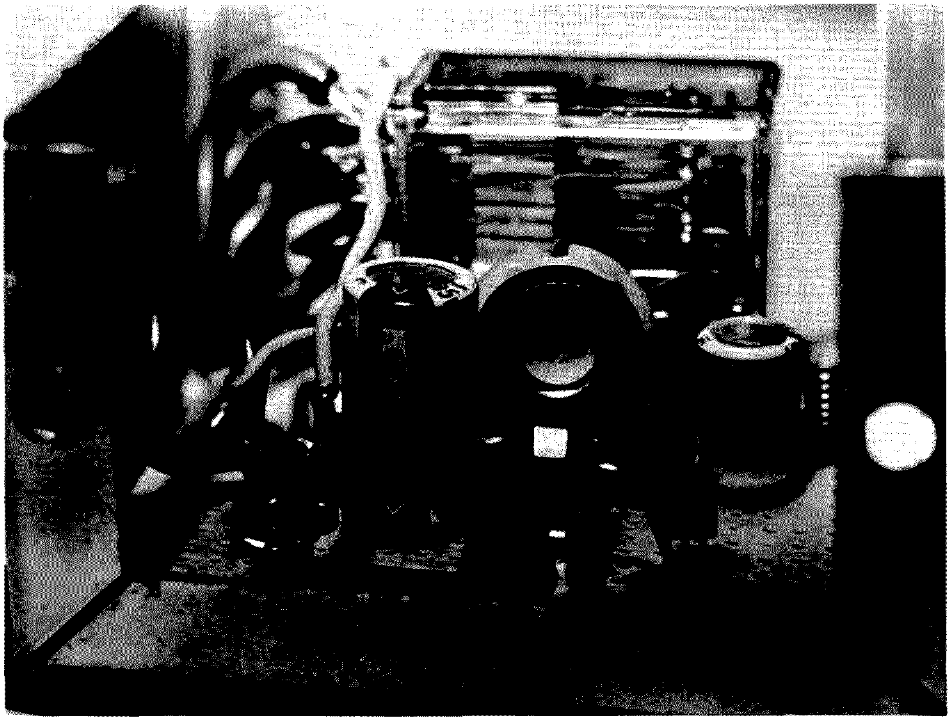

Photo of the turn signal timeout.

C3 is needed to prevent false resetting while flashing. My theory is that C1's delay keeps pins 2 and 4 high enough to prevent resetting during the time when the flasher opens the circuit. Somehow, C1 has to be electrolytic; a tantalum-type does not do the job. Too large a C1 causes a long reset delay.

Due to variations in forward voltage drop among silicon and germanium diodes, and due to variations in flasher rates, I suggest that the Q1 base resistor be a 250k trimpot. I found that it should be set at 80k us-

ing 1N914s, and 180k using 1N34s, in order to keep Q1 on, and thus charge C2. The exact resistance required is quite critical, but provides reliable operation, once determined.

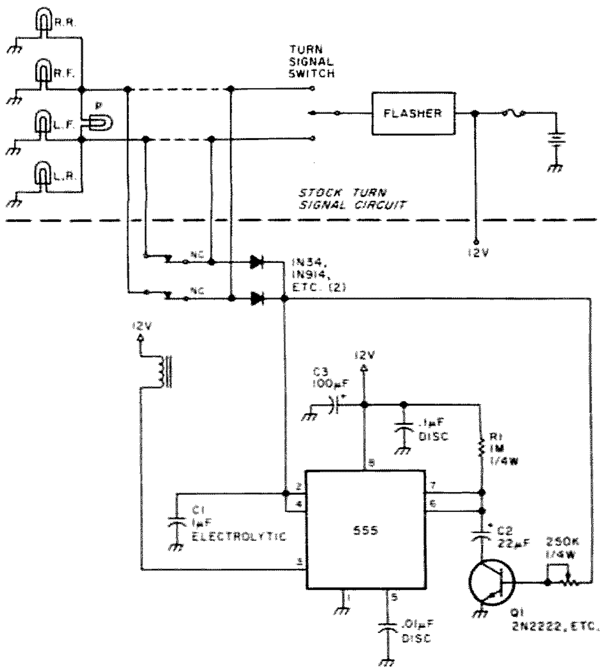
Time-out is determined by the formula: T(sec.) = 1.1 x R1 x C2. R1 is in megohms, C2 is in farads, and tolerances of components require experimentation, which explains my six-second discrepancy from the formula.

Any DPDT relay with 5-Amp, or so, contacts, and 12-volt coil should do, keeping in mind the 200-mA sinking capability of a 555. I used a Potter & Brumfield R10-E1-X2-V185.

I epoxied the relay to vectorboard, on which all components were mounted; this was stuck into a 1-5/8" x 2-1/8" x 2-3/4" minibox from the junk box. The six leads were brought out to a barrier terminal strip on the box. The box was installed under the left side cover of a Kawasaki 900 where, conveniently, there were two unused welded nuts on the battery box. After installation, my hindsight saw that there was space for the entire kludge under the tank. The circuit could be made much smaller for other machines, if called for.

Wiring to this bike required cutting the left and right turn signal wires after the switch; these were found in a harness under the fuel tank. These four points are then connected to the NC relay contacts, keeping in mind which is "in" and "out" for sensing purposes.

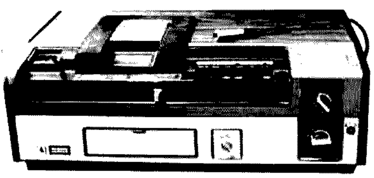
For fully solid state, I don't see why 2N3055-type transistors could not be used instead of a relay, if you want to tolerate their voltage drop. Knowing 555s, possibly the timer should be set longer for cold weather riders.



Schematic for the turn signal timeout.

It works! It's imperfect, and requires resetting in traffic jams. It even seems to make itself unnecessary by making one more conscious of its purpose!

Credit is due to K1ICU for his idea, and for the use of his Kaw as a guinea pig. ■



Looking West

from page 6

along these lines is a far better alternative than brute-force vigilantism, which lowers those involved to the level of the offender himself.

Finally, to those who still feel Scott Lookholder got off easy, let's look at the overall picture. Lawyers I have spoken with tell me that a viable estimate of his legal costs would be between 4 and 6 thousand dollars. Add to this another thousand to satisfy the fine, and financially it may have cost him close to $7,000. Only he and his attorney know for sure. Then, too, he has lost the use of something many of us hold dear: the ability to communicate via his amateur station. Remember, the court made it a provision of his probation that he not utilize his amateur privileges for at least a year. There is also the possibility that the FCC will begin proceedings to revoke his license, thereby making his QRT period permanent. Nobody knows if this will happen, but it is a distinct possibility. No, Scott Lookholder did not get off easy by a long shot. It cost him dearly, and hopefully it will be a lesson to others who have thoughts of engaging in similar illegal activities.

While we are on the subject of malicious interference, I would like to discuss another new type with you for a moment. One might almost call it "legal interference," but it is morally wrong nevertheless. It usually shows up when a group of two or three who want to see just how much they can get away with take over and monopolize a given repeater. They carefully structure their remarks so as to not violate any rules and regulations as set forth by the Commission, but nonetheless their statements are constructed in such a way as to "get the goat" of all others who may be listening. Usually, they will not recognize breakers, and those who do make it in find themselves harassed in one way or another. These bothersome people play it strictly by the rulebook, including proper station identification at the prescribed intervals. They always "stand on their constitutional right of freedom of speech" and in doing so take away yours and mine. If this sounds all too familiar, then you have such a faction in your home town.

What can be done about them? First, all of us have to remember that our amateur licenses are not a guarantee of freedom of speech. Rather, it is a privilege to communicate granted by our government, and it can be revoked any time the government sees fit. There are no rights stated or implied. Herein lies at least part of the solution. Since a repeater is not a public utility, the licensee is under no obligation to provide this service to those he deems are abusing it. The repeater owner-operator has one very effective weapon at hand: the ability to take away the toy from those who do not appreciate it. Many owners hesitate to take such action, fearing that a time will come when some user will want to make an emergency call and the system will be off. True, this can happen, but if the same amateur wants to make this call and the repeater is being abused by those who do not respect it, he will have no better chance then anyway. It is up to the technical minds who produced the myriad of FM relay devices which now stretch the length and breadth of this nation to fulfill their obligation to the amateur community by initiating a cleanup of the bad on-the-air operation. If they do not, and if abuses continue to grow, they will only have themselves to blame when the ax falls—when the FCC and other government agencies start to do it for them. Repeater owner-operators have more than just a technical responsibility to erect and maintain a system. There is also a moral obligation to ensure the proper utilization of a given system. If they fail in this, they should not be permitted the privilege of continued system ownership. The day in which a repeater owner-operator can isolate himself from the rest of the amateur community is long gone. His responsibilities are clear-cut and he must discharge them for the good of the community.

THE SOME-PEOPLE-NEVER-LEARN DEPARTMENT

Maybe it would be better to call this "Once Involved, Always Involved." This might be the motto of Bob Thornburg WB6JPI. After two years of political hiatus, Bob was elected earlier this month to the chairmanship of TASMA, the organization which replaced the old SCRA in the middle of 1978. Bob sees his job as one of uniting the various special interests which abound on two meters. Frankly, it looks as if he has his work cut out for him. While Association membership by those involved in other aspects of two meter operation has been steadily on the rise, repeater owners seem to be staying away as if to protect the organizational structure change.

Late last year, just around the time of the change, a rather vile letter was circulated to many or all area repeater owners calling for the destruction of the SCRA and its new open-door policy and "a return of political power to those competent to administer it." The letter went on to give steps which should be taken by repeater owner-operators to ensure that the above would indeed happen. However—and this is very important—the letter was basically unsigned, a condition which thus destroyed its overall credibility. Whether this letter has had anything to do with the lack of organizational interest on the part of repeater owner-operators cannot be determined. One thing is clear: They are staying away, and Bob will have quite a job during the next twelve months trying to bring them back into the fold. It won't be the first time that Bob has pulled off a miracle. He is very adept in that regard. Can he do it? If he can't, nobody can.

Already, Bob has support from virtually every other segment of southern California's two meter society, including the weak-signal people and repeater-user groups. Indeed, he is a very popular and well-respected individual in this area who honestly cares about his fellow man. He has taken on a very big responsibility, and we wish him well.

It's hard to find a reason for this lack of initiative on the part of this area's two meter repeater owners. No one reason seems to predominate. Some speculate that many of the oldliners who helped start voluntary coordination are just tired of the political arena and want out. As with any organization, attrition along these lines is to be expected. No one group of in-

In attendance at the TASMA meeting were Jim Rieger WA6EZL and ED Tippler WA6KYZ. Jim is probably the nation's best authority on linear translators.

Marlene Thornburg WD6FBI sips soda as Herb Gordon W6KBD explains her new duties as TASMA treasurer.

dividuals can be expected to stand in front of the firing line forever. In other cases, it's obviously apathy. They have their systems operational and nothing else concerns them. Why should they get involved? They need involvement like they need a headache. More predominant, however, is an unspoken sentiment which seems to say that the organization no longer represents those whom it was established to protect—the southern California repeater owner-operator—and that opening voting membership to all interested amateurs has weakened the political position of the repeater owner. Therefore, why should an owner-operator bother to keep membership in an organization in which he is no longer in the majority position. This was the view stated in the letter discussed earlier.

It's interesting to note that the 220-SMA, which was formed at the same meeting, suffers none of these ills. The 220 people of this area, system owner and spectrum user alike, seem very together in their goals and viewpoints. Structurally, the two organizations are almost identical, yet 220 keeps its repeater owners as members while two meters can't. Why the unity on 220 not found on two meters? Is it because all 220 spectrum users see the US WARC proposal as a common enemy? Is it that they have watched the development of two meters and have sworn that the same pitfalls will never occur on 220? No one can rightly say. However, at this time, the 220 people of this area are far more together than any other group. Perhaps it's time for everyone to step back and take a good look at what has put them in such a position. The 220-SMA is going strong, and we can all learn from them.

All the above might lead you to believe that two meters in this area is in a disastrous state. Far from it. TASMA's 2 meter band plan has been accepted without complaint, and while repeater owner support is dwindling, support from all other sectors of the two meter society is strong and growing. However, making overall spectrum management work takes the ongoing cooperation of all users. Those who own and operate repeaters are a key part of two meters, and it's to soliciting their active support that Bob and his staff will be dedicated.

DX-ON-A-REPEATER DEPARTMENT

Southern California is known as an area of "repeaters with a purpose." Over the past few years, we have seen systems developed for just about every reason under the sun, including one for the exclusive use of school children. Now, thanks to the Southern California DX Club, even HF DXers have a meeting ground of their own. According to club president Dave Bell W6AQ, while not the first system of its type in the nation, the AD6P/R system will serve as more than just a local gab channel for DXers. The club has great plans for the newly established system, and the future seems bright with promise. Already, it is used to alert members as to where the rare ones can be found. In the future, one might even hear actual on-the-air seminars on the art of DX-chasing.

While its prime usership is made up of DXers, AD6P (144.88 in/145.48 out) is an open repeater which invites all area amateurs as well as visitors to Los Angeles to utilize its facilities. If you happen through LA and want to meet some of its top DX enthusiasts, then drop in on the system or, if time permits, attend one of their club meetings. You will find either one a rewarding experience.

ON-THE-MOVE DEPARTMENT

Jim Hendershot WA6VQP, network director for Westlink, asks that I pass along the news that the new Westlink studio facilities are fully operational at their new location in Canoga Park, California. The new studio features such amenities as cartridge tape units used to gather and pre-edit items for the newscast and additional post-production duplicating equipment to cut down the reproduction time of finished cassettes. He still hopes to expand the reproduction facilities further when funds permit the acquisition of more cassette recorders.

What started a year and a half ago as a small undertaking to produce a weekly amateur radio news program has grown to an enterprise which serves the news needs of thousands of amateurs nationwide. Now in its seventy-second week of consecutive operation, the Westlink Amateur Radio News Service has become a vital link in keeping us all informed of events which affect our day-to-day operation. It is still free to any group or individual who supplies blank cassette tapes in SASE mailers. For more information about this service, contact Jim at Westlink's new address: 8331 Joan Lane, Canoga Park CA 91304.

HF INTERNATIONAL: AN OUTSIDER LOOKS IN

It was not until after I arranged the interview with Norm and Jeanne Meuller that I first bothered to listen to the spectrum HFI calls its home, CB channels 32 through 40. I expected to hear the same type of "10-4 Good Buddy" operation as is found on what CBers call the "lower 23," but was quite taken aback by what I actually heard. Frankly, it sounded a lot closer to 20 or 40 than to what I expected. Operation seemed very structured and in no way haphazard. Other than the strange-sounding dual callsign bit (HFI members utilize both their assigned FCC callsign and their HFI call or "HF number"), the operation seemed as if it could be taking place on any of the amateur bands. I was shocked, perplexed, and maybe a bit mad. After all, here I proudly sat with an amateur license displayed on the wall. Who were these people to play ham without bothering to be hams!

The following Sunday I met with Norm and Jeanne. Upon entering Norm's office, I noted two things immediately: an absolutely marvelous amateur station in one corner, and a large poster of Jerry Lewis touting HFI in relation to the annual MDA campaign. Inquiring, I learned two things right off the bat. It was indeed an amateur station, and Norm was licensed to use it. "My god," I thought to myself. "An amateur runs HFI?" The MDA poster was also explained. HFI and its close to 50,000 active members would be participating in the 1978 Labor Day Jerry Lewis telethon. I thought again to myself: "These are the bad guys who are out to destroy ham radio? The bad guys everyone had told me about? Something doesn't jive. Bad guys don't do nice things like this!"

The questions I asked ranged from simply what was HFI and its goals to what their official stand was on specific matters. Basically, here is what I learned: HFI is an organization of hobby-type SSB users operating in the upper portion of the 27 MHz personal radio band. It was founded to promote the use of SSB communication in that particular spectrum and to give the SSB CB hobbyist an organizational structure of his own. At its peak, HFI boasted more than 90,000 members, but this was prior to the reorganization. Though it is still quite large—probably still better than 50,000 at the latest estimate—no exact figure was available at the time of the interview.

Norm asked that I make it clear that HFI does not condone the use of excessive and illegal power levels or out-of-band operation. In his remarks, he made it clear that an HF number does not always mean that the holder is a current HFI member. Therefore, those operating illegally between the 11 and 10 meter bands are not necessarily HFI members, though some may still use their HFI numbers issued many years ago. All of the foregoing has been reiterated to the members of HFI in recent membership mailings, in which Norm stressed the need for legality in day-to-day on-the-air operation. Another point I was asked to emphasize was that HFI, under the current direction of Norm and Jeanne Mueller, never backed or condoned in any way the actions of Mr. Richard B. Cooper or his Communications Attorney Service. Norm's basic commentary was that Cooper/CAS was detrimental to both the amateur and CB services and would eventually cause both harm. Contrary to popular belief in amateur circles, HFI was not one of Cooper's ardent supporters.

Norm sees today's HFI as an intermediate ground between AM CB radio and the amateur service. He would like to see HFI take an active role in helping the CBer make the change, with as minimal an environmental impact on the amateur service as possible. He believes that the education of the transitioning CBer is the key. However, such education can only come about if the FCC acts to create "SSB only" channels wherein the AM CBer can get away from the "10-4 Good Buddy" attitudes of AM and learn proper operation from his SSB-minded peers. HFI feels that if such were the case, actual on-the-air amateur-oriented training could be accomplished (especially if CW were permitted).

As an amateur himself, Norm sees one of amateur radio's greatest problems today to be the uninitiated AM CBer who has the technical expertise to obtain an amateur license but has never been educated in the moral and operational values which amateurs associate with their hobby. He specifically cites many of the problems prevalent on FM repeaters as an example of this lack of proper indoctrination. Again, in relation to the amateur service, he sees this as an avenue for active HFI involvement.

While HFI would like more SSB-only spectrum for its members, Norm does not feel that it should come from the amateur bands. Rather, HFI endorses proposals which would place such spectrum directly next to the current 40-channel Class D allocation and above it in an area below 10 meters (with a buffer zone between the two). HFI feels, however, that such can only come to pass if all HF members obey the current regulations as written—especially those regarding proper station identification at prescribed intervals and respect for band-edge and power limitations. The

organization knows that only a mass show of good faith to the FCC will have any meaning. To that end, HFI's literature constantly reminds its members of these precepts.

Above all, HFI wants to become a respected member of the hobby radio community. They want amateurs especially to know that they are not the enemy. They want to be considered as friends and working partners. It has taken me a year to sit down to write this, a year of waiting to see if I was being handed something substantial or just hot air. I have followed HFI's progress these past 12 months, and what I was told a year ago is substantially true today. Norm and Jeanne Mueller are two people who are sincerely devoted to their beliefs and who are very positive-thinking people. Under their leadership, HFI has taken many giant leaps toward its prime goal.

Whether you like or dislike organizations such as HFI is unimportant. What does count is that today's non-amateur hobby radio enthusiasts are responsible for a good percent of all personal radio operation and cannot be ignored. There are many myths these days in amateur circles about how anyone who owns a CB radio is a bad guy. Myths they are, and as such they should be dispelled. There are good guys and bad guys in every walk of life. We have both in amateur radio, and I'm sure that Norm has both in HFI. What is important is learning that we are all human beings with a common interest, even though we may express this interest in different ways. HFI has said to us, "We want to be your friend and work with you." What will our answer be? You can let me know, or you can write directly to Norm c/o HF International, PO Box 7576, Riverside CA 92513.

THE WHATEVER-HAPPENED-TO-??? DEPARTMENT, REVISITED

Without warning recently, the FM and Repeater column seems to have disappeared from *QST!* It's well known that its editor, Lou McCoy W1ICP, has retired from active League duties and now lives in one of my favorite places, New Mexico. I sincerely wish Lou many prosperous years of retirement, as well as many more happy years of hamming.

However, Lou's departure seems to have left a rather big gap in Newington, one that should be filled quickly. In this day and age, when FM is on the lips of virtually every amateur, *QST* cannot afford to be without such a service to the ARRL membership. The column is necessary, and I, speaking as one ARRL member, would like to see it reinstated. Perhaps one of you reading this is willing to offer your services to the ARRL. Lou did a fine job with it, and his act will be hard to follow.

Microcomputer Interfacing

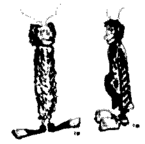
from page 28

This means that one subroutine may call another. In this way, a control subroutine may, in turn, call a timer subroutine. When the timer subroutine has completed its task, it causes a return to the control subroutine. This situation requires two levels on the stack, or four R/W memory locations, since two full 16-bit return addresses must be maintained on the stack while the timer subroutine is in operation: (1) the return address for the timer-to-control link, and (2) the return address for the control-to-main-task link. *The stack operations take place automatically whenever a call or a return is executed.* The call and return instructions may be either conditional or unconditional, but each subroutine must contain at least one return instruction.

Recall that the 8080 chip contains seven 8-bit general purpose registers, the accumulator (A), B, C, D, E, H, and L. In programs where subroutines are used, there may be register conflicts since the subroutine and the main task may both require the use of a specific register. Sometimes this problem may be solved by choosing another register, but this is not always possible, particularly when the A register and the flags are involved. To avoid register conflicts, it is possible to use the stack for temporary data storage. All of the internal 8080 registers may be pushed onto the stack and popped back into the 8080 as needed. Data is stored and retrieved as register pairs, with register A and the flags forming a two-byte word which is treated as a register pair.

The subroutine in Table 1 is a time delay routine in which registers D, E, A, and the flags are stored on the stack. At the completion of the subroutine, the data stored on the stack is retrieved and placed back in the internal registers. The complementary operations of stack storage and retrieval are called *push* and *pop*, respectively. Notice that the stack pointer is initialized at the start of the program, before any other instructions are executed.

The use of subroutines in a program allows many complex tasks to be subdivided into small segments which are easy to link together and which relieve the problem of continuously rewriting frequently used program steps and routines. You will find that a personal library of frequently used subroutines is indispensible when you are programming.



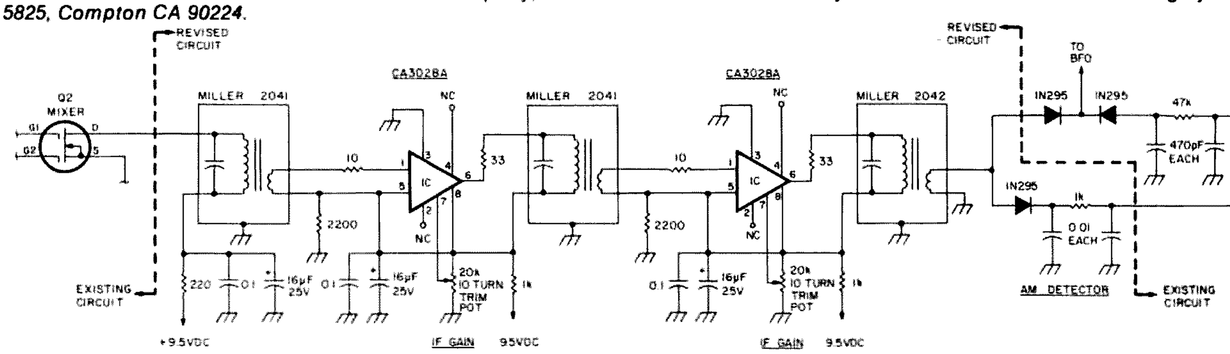
Corrections

I have recently been advised that J. W. Miller Company no longer has the 8901-B and 8902-B i-f units which I used in my circuit on pp. 48-49 of the January, 1979, issue of *73* ("Building an Economy Receiver").

I have enclosed a copy of a revised i-f circuit which does use currently-available components.

Tom McLaughlin WB4NEX
St. Petersburg FL

Fig. 1. Revised i-f circuitry, "Building an Economy Receiver." Resistors are ½-W, 10%. Miller 455-kHz transformer: #2041—input 25k, 600-Ω impedance; #2042—output 25k, 1-kΩ impedance. Transformers are available from J. W. Miller Company, PO Box 5825, Compton CA 90224.



There are two errors in my article, "A Single IC Time Machine," which appears on page 148 of the February issue.

Both errors are in Fig. 15. In Fig. 15(a), the error is caused by a possible "smear." At the top of the figure, near the middle, there is a pad for the −5-V regulator. This pad is shown connected to the adjacent circuitry by a fine line. This fine line is possibly a "smear" from the original silk screen and should be removed.

The second error will raise a lot of eyebrows. Basically, it is an inversion. The grey area of

the PCB of Fig. 15(a) should be rotated 180° on the darker overlay.

H. M. Knickerbocker K6SK
La Mesa CA

In response to a letter from one of our readers, Lee Reed W5VRC (ex-W4RBL), author of "Build An Economy Zener Checker" (February, 1979, page 137), would like to comment on his zener checking circuit.

The problem is the inherent danger of a transformerless line-operated power supply.

Should the "hot" side of the ac line be inadvertently connected to the "common" side of the unit, as it would if the ac plug were inserted backwards into a receptacle or if the ac socket is miswired, it is possible to get line voltage between the common side (which the user may be holding) and an external ground.

As a remedy for this, the use of a small isolation transformer is recommended or, at the very least, a 1k 2-Watt resistor should be added in series with the fuse.

A few dollars spent on a transformer is certainly worth the safety which it affords.

In my article in the September, 1978, issue ("Nuclear Attack!"), I left out a very important "=" at step 193. Here is a procedure to fix the program:
1) Load the bad program into memory;
2) Press:
GTO 193
LRN
2nd Ins
=
LRN

This will insert the "=" between the "B" and the "X". I apologize to all.

I have been receiving requests for a version of the game to run on the TI 58/59. I will be glad to send anyone a program listing for this machine, provided the request is accompanied by an SASE.

Dan Everhart WA7WKA
293 Lander Hall
University of Washington
Seattle WA 98105

In "Impedance and Other Ogres" (February, 1979, page 47, column 1), the fourth and fifth lines from the bottom read, in part: "... $P_{AV} = E_{RMS} \times \cos\theta$." Since we do indeed believe in Ohm's Law, the formula should read: $P_{AV} = E_{RMS} \times I_{RMS} \times \cos\theta$. To our readers and Georg Simon Ohm, we apologize.

Review

When the *1979 Radio Amateur's Handbook* made its appearance last November, I was probably the first on the block to pay $9.75 and take a paperback copy home. The ARRL has put a lot of effort into promoting the *1979 Handbook* as being new and different. My 1974 edition is worn from heavy use and I moved it aside, making room for the newcomer, with a bit of reluctance.

The most obvious change in the new *Handbook* is the size. Like *QST*, the *License Manual*, and other League publications, the *Handbook* has gone to the bigger 8½" x 11" format. The new size makes older *Handbooks* look small and unimportant, but a quick weighing revealed that it was a scant 3½ ounces heavier than the 2-pound 1974 edition.

Old-timers will be glad to know that Ohm's Law is still V = IR in the elementary theory section. The basic principles haven't changed, but the theory chapters have been either completely or partially rewritten. Both beginning and experienced hams will find the "Radio Design Technique and Language" chapter useful. In addition to a comprehensive discussion on tuned circuits, a glossary of radio terms is included.

A chapter on vacuum-tube principles will not be found in the *1979 Handbook*; in its place there is a greatly expanded chapter on solid-state fundamentals. The *Handbook* editors have limited the coverage of this vast topic to those devices and applications that are most applicable to general amateur use.

The chapter on HF transmitting contains a number of charts and graphs that eliminate some of the drudgery of design calculations. The *Handbook*'s new size seems to lend itself well to this kind of presentation. Throughout the edition, graphs and charts are included. One conspicuous area is missing, however. Gone is the index of tube specifications and base diagrams. The token coverage of solid-state device specs has also been deleted.

One of the most repeatedly mentioned attributes of the *1979 Handbook* is the "Narrow Band Voice Modulation" chapter. The *Handbook*'s coverage of NBVM is largely a rehash of the *QST* articles and, in some cases, is a word-for-word reproduction. Experimenters looking for parts suppliers and discrete filter design information will be very disappointed.

In the enthusiasm for NBVM, such modes as RTTY, slow scan, and facsimile seem to have been forgotten. It is ironical that a book devoted to state of the art neglects even a short reference to these "specialized communications techniques" that many ham/experimenters are involved in. ARRL publications are sorely lacking in this area.

In keeping with the state-of-the-art theme, the FM and repeater chapter includes information on tone-decoding circuitry as well as a "practical synthesizer." However, there is no complete schematic for an FM transmitter or receiver. In this chapter as well as in most of the others, the editors have chosen to include many subcircuits dealing with a specific part of a rig.

The chapters on propagation, transmission lines, and antennas have been partially rewritten. Theory sections tend to be more mathematically oriented than earlier editions, while specific construction details are fewer.

If you are an "appliance operator" who doesn't care how your station works, then you may find the *Handbook* to be a waste of money. Highly knowledgeable hams looking for the latest in microprocessor control will probably be disappointed with the *1979 Handbook*. Beginners searching for a wire-by-wire description on building their first rig may be frustrated with the *Handbook*'s contents. Like its predecessors, the *1979 Radio Amateur's Handbook* is not a rigorous text on electronic theory; instead, it is a reference and idea book for hams willing to think.

AMATEUR EXTRA CLASS LICENSE

Eliminating Granting of Credit Toward the Telegraphy Portion of Examination to Former Holders of the Amateur Extra First Class License

AGENCY: Federal Communications Commission.

ACTION: Notice of proposed rulemaking.

SUMMARY: The Commission is proposing to delete § 97.25(d) from its Rules. This provides credit toward the telegraphy portion of the Amateur Extra Class license examination to holders of the former Amateur Extra First Class license and its successor licenses.

DATES: Comments shall be filed by April 30, 1979, and Reply comments shall be filed by May 30, 1979.

ADDRESSES: Comments shall be filed with: Secretary, FCC, 1919 M Street, N.W., Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT:

Mr. Philip W. Savitz, Personal Radio Division, (202) 632-7175.

SUPPLEMENTARY INFORMATION:

Adopted: February 14, 1979.

Released: February 27, 1979.

By the Commission: Commissioner Quello absent.

1. In accordance with the Administrative Procedure Act, 5 U.S.C. 553, and § 1.412 of the Commission's Rules, the Commission hereby gives Notice of Proposed Rule Making in the above captioned matter.

2. During the period from June 1923 to June 1933 the Federal Radio Commission issued Amateur Extra First Class operator licenses. Subsequently, the equivalent license issued by the Federal Communications Commission was designated "Class A," and then "Advanced."

3. In 1952 the Commission created the Amateur Extra Class license. Obtaining this license requires successful completion of written examinations in nine areas of basic, general, intermediate and advanced amateur practice. These written examination requirements are much more stringent than those associated with the Amateur Extra First Class license. However, the telegraphy proficiency requirement for the Extra First license was 20 words per minute, which is the same as the current requirement for the Amateur Extra Class license.

4. Recognizing this identical telegraphy requirement, the Commission, in its Report and Order in Docket No. 19163, released on September 13, 1972, amended § 97.25(d) of its Rules to provide that credit for the telegraphy portion of the Amateur Extra Class examination be granted to applicants who present proof of having continuously held the Amateur Extra First Class license and its successor licenses.

5. Section 97.25(d) has now been in effect for more than six years. Recently, the number of persons seeking examination credit pursuant to this provision has declined to the point where such an application is now a rarity. As it appears that § 97.25(d) has become obsolete, the Commission is proposing its deletion from the Rules, effective six months from the adoption of such an order. This delay will give any former holder of the Amateur Extra First Class license who may remain a final opportunity to receive telegraphy credit toward the Amateur Extra Class examination.

6. The specific rule amendments we are proposing are set forth below. Authority for these proposals is contained in Sections 4(i), 5(e), and 303 of the Communications Act of 1934, as amended. We invite interested parties to submit comments concerning our proposals on or before April 30, 1979, and reply comments on or before May 30, 1979. An original and five copies of

all comments and reply comments shall be furnished the Commission, pursuant to § 1.419 of the Rules. Respondents wishing each Commissioner to have a personal copy of the comments may submit an additional six copies. Members of the public wishing to express interest in our proposals but unable to provide the required copies may participate informally by submitting one copy of their comments, without regard to form, provided the correct Docket number is specified in the heading of the comments. All comments and reply comments filed in this proceeding should be sent to the Secretary, Federal Communications Commission, Washington, D.C. 20554.

7. Individuals wishing to inspect the comments and reply comments filed in this proceeding may do so during regular business hours, 6:00 A.M. to 5:30 P.M., Monday through Friday, in the Commission's Public Reference Room, 1919 "M" Street, N.W., Washington, D.C. 20554.

8. For further information contact Mr. Philip W. Savitz, Personal Radio Division, FCC, 1919 "M" Street, NW, Washington, D.C. 20554, (202) 632-7175.

FEDERAL COMMUNICATIONS COMMISSION,
WILLIAM J. TRICARICO,
Secretary.

The Federal Communications Commission proposes to amend Part 97 of Chapter 1 of Title 47 of the Code of Federal Regulations as follows:

§ 97.25 [Amended]

1. In § 97.25 paragraph (d) is deleted and paragraph (e) is redesignated as paragraph (d).

PART 2—FREQUENCY ALLOCATIONS AND RADIO TREATY MATTERS: GENERAL RULES AND REGULATIONS

PART 97—AMATEUR RADIO SERVICE

Amendments of Rules Concerning the Northern Mariana Islands

AGENCY: Federal Communications Commission.

ACTION: Order (Rulemaking).

SUMMARY: The Northern Mariana Islands has recently been added to the Commission's jurisdiction. Certain charts and tables in the amateur rules are being amended to reflect this change in the Commission's jurisdiction.

EFFECTIVE DATE: March 13, 1979.

ADDRESSES: Federal Communications Commission, 1919 "M" St. NW., Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT:

Mr. Robert Cassler, Private Radio Bureau (202-634-6620).

SUPPLEMENTARY INFORMATION:

In the matter of amendments of Parts 2 and 97 of the Commission's rules concerning the Northern Mariana Islands.

Adopted: February 22, 1979.
Released: March 2, 1979.
By the Commission:

1. On January 9, 1976, as a step toward eventual political union with the United States as a Commonwealth, the Northern Mariana Islands came under the jurisdiction of those laws of the United States which have general applicability to the several States. Previously, these islands were administered by the United States for the United Nations as part of the Trust Territory of the Pacific Islands, and those persons seeking authorization to operate a radio station were required to apply to the High Commissioner of the Trust Territory of the Pacific Islands. As of January 9, 1976, the Communications Act of 1934, being a law of general applicability to the several States, became applicable to the Northern Mariana Islands, and jurisdiction over radio stations on the Northern Mariana Islands passed from the High Commissioner to the Federal Communications Commission.

2. Certain amendments to the rules governing the Amateur Radio Service in Parts 2 and 97 of the Commission's Rules are necessary to reflect the change of status of the Northern Mariana Islands. Two minor amendments to Parts 2 and 97 concern the frequency bands available to amateur radio operators on the Northern Mariana Islands. The Northern Mariana Islands lie in Region 3. Most of the rest of the United States lies in Region 2. International allocations for the Amateur Radio Service are different for Region 3 than for Region 2. Footnote NO62 to § 2.106 and § 97.61(b)(4) are being amended to reflect this.

3. The other two amendments concern the use of the 1800-2000 kHz amateur band. Because this band is shared with the radionavigation (LORAN-A) service, input power is limited according to geographic area. The charts in footnote NG15 to § 2.106 and § 97.61(b)(2) are being amended to add the Northern Mariana Islands to the list.

4. Authority for these rule changes is contained in Sections 4(i) and 303 of the Communications Act of 1934. Because these amendments are basically minor changes in the rules to reflect the addition of the Northern Mariana Islands to the Commission's jurisdiction, the Commission finds that, for good cause, the notice and public procedures provisions of the Administrative Procedure Act are unnecessary (5 U.S.C. 553(b)). For more information about these rule changes, contact Mr. Robert Cassler, Personal Radio Division, FCC, 1919 "M" Street, NW., Washington, D.C. 20554 (202-634-6620).

5. Accordingly, it is ordered that, effective March 13, 1979, Part 2 and Part 97 of the Commission's Rules are amended as set out in the Appendix.

(Secs. 4, 303, 48 Stat., as amended, 1066, 1082; 47 U.S.C. 154, 303.)

FEDERAL COMMUNICATIONS COMMISSION,
WILLIAM J. TRICARICO,
Secretary.

APPENDIX

Part 2 of Chapter I of Title 47 of the Code of Federal Regulations is amended as follows:
1. In Section 2.106, footnote NG15, and footnote NG 62 are amended to read as follows:

§ 2.106 Table of frequency allocations.

* * * * * * *

NG15 * * *
(a) * * *
(4) * * *

MAXIMUM DC PLATE INPUT POWER IN WATTS

Area	1800-1825 kHz Day/Night	1825-1850 kHz Day/Night	1850-1875 kHz Day/Night	1875-1900 kHz Day/Night	1900-1925 kHz Day/Night	1925-1950 kHz Day/Night	1950-1975 kHz Day/Night	1975-2000 kHz Day/Night
*	*	*	*	*	*	*		
Baker, Canton, Enderbury, Howland...	100/25	0	0	100/25	100/25	0	0	100/25
Guam, Johnston, Midway, Northern Mariana	0	0	0	0	100/25	0	0	100/25
American Samoa	200/50	0	0	200/50	200/50	0	0	200/50
*	*	*	*	*	*	*		

NG62 Consistent with Resolution 10, Radio Regulations, Geneva, 1959, interregional amateur contacts in this band should be limited to that portion between 7000 and 7100 kHz. In the band 7100 to 7300 kHz, the provisions of No. 117 of the Radio Regulations, Geneva, 1959, are applicable. In addition, 7100 to 7300 kHz is not available in the following U.S. possessions: Baker, Canton, Enderbury, Guam, Howland, Jarvis, Northern Mariana Islands, Palmyra, American Samoa and Wake Islands.

* * * * * * *

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended as follows:
2. In Section 97.61, paragraphs (b)(2) and (b)(4) are amended to read as follows:

§ 97.61 Authorized frequencies and emissions.

* * * * * *

(b) * * *
(2) * * *

MAXIMUM DC PLATE INPUT POWER IN WATTS

Area	1800-1825 kHz Day/Night	1825-1850 kHz Day/Night	1850-1875 kHz Day/Night	1875-1900 kHz Day/Night	1900-1925 kHz Day/Night	1925-1950 kHz Day/Night	1950-1975 kHz Day/Night	1975-2000 kHz Day/Night

Baker, Canton, Enderbury, Howland...	100/25	0	0	100/25	100/25	0	0	100/25
Guam, Johnston, Midway, Northern Mariana	0	0	0	0	100/25	0	0	100/25
American Samoa	200/50	0	0	200/50	200/50	0	0	200/50
*	*	*	*	*	*	*		

(4) 3900-4000 kHz and 7100-7300 kHz are not available in the following U.S. possessions: Baker, Canton, Enderbury, Guam, Howland, Jarvis, the Northern Mariana Islands, Palmyra, American Samoa and Wake Islands.

Ham Help

An obviously demented *73* author is looking for 455-kHz i-f components. These may be anything from standard i-f transformers to moderately-priced crystal and ceramic filters.

They must be easily applied and usable with a wide range of solid-state devices, from junk-box transistors to IC devices—also, with tubes if possible. They must give good results in an i-f strip used for CW and/or SSB receiver use.

Manufacturers, distributors, or surplus dealers foolish enough to provide me with technical info, application notes, and an easy way for *73* readers to get their hands on the goodies may find themselves pestered unmercifully by *73* readers wanting to purchase parts to see if the circuit really works.

Alexander MacLean
WA2SUT/NNN0ZVB
18 Indian Spring Trail
Denville NJ 07834

I need help in converting a Drake TR-3 to semi-break-in CW. I feel that there must be some circuits for this obvious improvement of the TR-3 which possibly appeared in ham magazines in the 60s.

At present, my 15-year-old TR-3 must be manually switched between transmit and receive. The successor to the TR-3, the TR-4, injects a tone into the grid of the VOX amplifier circuit. Possibly, the same may be accomplished with the TR-3.

Ron Yokubaitis WB5TKQ
PO Box 3554
Austin TX 78764

I need the RCA manual sections for the high-band CMC-60 FM 60-Watt "boat anchor" rig (transmitter and dynamotor power supply only). I will duplicate and return within one week.

Staten Island NY 10310

Contests

from page 21

AWARDS:

The ITU Trophy will be awarded to the country which earns the highest number of points computed as described above. The country which wins for 3 consecutive years or 5 interlaced years will remain in possession of the trophy. The trophy will be awarded to the representative national association of radio amateurs of the winning country. Gold, silver, and bronze medals will be awarded to the 3 highest-scoring radio amateurs in the world on each mode. Certificates will be awarded to the highest-scoring radio stations in each country on each mode. Depending on the number of contestants in each country, the contest committee will consider more certificates.

ENTRIES:

Logs will be filled out separately for each mode. Logs will follow the standard form and must be mailed before 30 June 1979. Address entries to: LABRE, UIT Contest Coordination, PO Box 07-0004, 70.000—Brasilia, DF, Brazil. Logs received after August 30 will not be computed for awards. Include a QSL, a self-addressed label, and IRCs for personal contest results. Note: Look for special ITU calls worldwide!

ARMED FORCES DAY
May 19, 1979

This year's observance of Armed Forces Day marks three decades of communications tests between the amateur radio fraternity and military communications systems. Since 1950, this event has been scheduled during the month of May and has emphasized a continuing climate of mutual assistance and warm esteem. Saturday, May 19, 1979, has been designated as the 30th Annual Armed Forces Day.

A featured highlight of the nationwide celebration will be the traditional military-to-amateur crossband communications tests. These tests give amateur operators an opportunity to demonstrate their individual technical skills and to receive recognition from the Secretary of Defense or the appropriate military radio station for their proven expertise.

The proceedings will include operations in continuous wave (CW), single sideband voice (SSB), radioteletype (RTTY), and slow-scan television (SSTV).

Special commemorative QSL cards will be awarded to amateurs achieving a verified two-way radio contact with any of the participating military radio stations. Those who receive and accurately copy the Armed Forces Day CW and/or RTTY message from the Secretary of Defense will receive a special commemorative certificate from the Secretary. Interception by shortwave listeners (SWLs) is not acknowledged by QSL cards; however, anyone can qualify for a certificate by copying the Secretary's message.

Crossband Radio Contacts

The military-to-amateur crossband operations will be conducted from 19/1300 UCT (Universal Coordinated Time) to 20/0245 UCT May 1979. Military stations will transmit on selected military frequencies and listen for amateur stations on those portions of the amateur bands indicated in Table 1. The military operator will specify the particular frequency in the amateur band to which he/she is listening. Duration of the contact should be limited to three minutes.

Station	Military Frequency (kHz)	Emission	Appropriate Amateur Band (MHz)

AIR 2045th Communications Group Andrews Air Force Base Washington, D.C.	4025, 7315, 13997.5

Table 2.

CW Receiving Test

The CW Receiving Test will be conducted at 25 words per minute. The broadcast will be a special Armed Forces Day message from the Secretary of Defense to any amateur operator desiring to participate. A ten-minute CQ call for tuning purposes will begin at 20/0300 UCT. The Secretary of Defense message will be transmitted at 20/0310 UCT from the stations on the listed frequencies in Table 2.

RTTY Receiving Test

The Radioteletype (RTTY) Receiving Test will be transmitted at 60 words per minute. Radio station "AIR" will transmit using 850 Hertz (wide) shift. All other stations will transmit using 170 Hertz (narrow) shift. A ten-minute CQ call for tuning purposes will begin at 20/0335 UCT. The special Armed Forces Day message from the Secretary of Defense will be transmitted at 20/0345 UCT. This test is to exercise the technical skill of the amateur operator in aligning and adjusting equipment. Transmission will be from the same stations and on the same frequencies as listed for the CW Receiving Test.

Submission of Test Entries

Transcriptions should be submitted "as received." No attempt should be made to correct possible transmission errors.

Time, frequency, and callsign of the station copied as well as the name, callsign, and address (including zip code) of the individual submitting the entry must be indicated on the page containing the message text. Each year, a large number of acceptable copies are received with insufficient identification information, or the necessary information was attached to the transcript and became separated, thereby precluding the issuance of a certificate.

Entries should be submitted to the appropriate military command and postmarked no later than 25 May 1979.

Stations copying NAM, GXH, NPG, or NDT submit entries to: Armed Forces Day Test, Chief, Navy-Marine Corps MARS, Bldg 13, NAVCOMMU WASHINGTON, Washington, D.C. 20390.

Stations copying WAR submit entries to: Armed Forces Day Test, Commander, United States Army Communication Command, ATTN: CC-OPS-MARS, Fort Huachuca AZ 85613.

Stations copying AIR submit entries to: Armed Forces Day Test, 2045th COMM GP/DONV, Andrews Air Force Base, Washington, D.C. 20331.

MASSACHUSETTS QSO PARTY
Starts: 1200 GMT May 19
Ends: 2200 GMT May 20

This year's contest is sponsored by the Greater New Bedford Contesters. A station may be worked once per band, with phone and CW being separate bands for the purposes of this contest. No crossband or repeater contacts are permitted. Mobiles and portables may be counted as new contacts each time a county change takes place. DX stations count for QSO points only when worked by MA stations.

EXCHANGE:

RS(T) and MA county or state/VE province.

SCORING:

All stations count 2 points for each completed SSB exchange, 4 points for each CW exchange. MA stations multiply QSO points by total MA counties worked plus states and provinces worked. Out-of-state stations multiply QSO points by total number of MA counties worked. As an added bonus, add 5 points to your total score for each sponsor station worked (W1FJI, N1AS, K1KJT); sponsors can only be worked once for bonus points.

AWARDS:

Certificates will be awarded to 1st, 2nd, and 3rd place winners in each MA county as well as each state. Two special awards will be given—one to the ARC with the highest aggregate score in MA (min. of 3 logs), and a second award to the station in MA who submits the all-time highest number of QSOs (now held by N1YY at 664 QSOs in 1978). In addition, a certificate will be given to stations working all 3 sponsors.

SUGGESTED FREQUENCIES:

CW only—1810, 3560, 3720, 7060, 7120, 14060, 21060, 21120, 28060, 28120.

Phone only—1820, 3960, 7260, 14290, 21390, 28590, 50.110.

Use of FM simplex is encouraged; CW must be in CW bands only!

LOGS & ENTRIES:

Logging must conform to FCC rules—date, time, band, mode, callsign, state and province worked, exchange RST. Submit separate summary sheet along with logs. Summary sheet information: name, call, mailing address, club affiliation for aggregate score, total QSO points, multipliers, and total score. Deadline for mailing is June 30. For awards and results, send an SASE to Arthur Marshall W1FJI, 60 Meadow Rd., Westport MA 02790.

MICHIGAN QSO PARTY
Contest Periods
1800 GMT Saturday, May 19 to 0300 GMT Sunday, May 20
1100 GMT Sunday, May 20 to 0200 GMT Monday, May 21

Sponsored by the Oak Park ARC with phone and CW combined into one contest. Michigan stations can work MI counties for multipliers. A station may be worked once on each band/mode. Portable/mobiles may be counted as new contacts each time county changes.

EXCHANGE:

RS(T), QSO number, QTH = MI county or state/country.

SCORING:

Multipliers are counted only once. MI stations score 1 point per QSO times sum of states, countries, and MI counties on phone. Each CW contact is 2 points per QSO. KL7 and KH6 count as states. VE counts as a country. Max. multiplier is 85. Non-MI stations score QSO points times number of MI counties. QSO points are as follows: 1 pt. for each MI phone QSO, 2 points each CW QSO, 5 points each club station contact W8MB. Max. multiplier is 83. VHF-only entries same as above except multipliers per VHF band are added together for total multipliers. No repeater contacts allowed, but 5 points for each OSCAR QSO.

FREQUENCIES:

CW—1810, 3540, 3725, 7035, 7125, 14035, 21035, 21125, 28035, 28125.

Phone—1815, 3905, 7280, 14280, 21380, 28580.

VHF—50.125, 145.025.

AWARDS:

Only single-operator stations qualify. MI trophies to high MI score, high MI (upper peninsula) score, high aggregate club score. Plaque to high VHF-only entry and high mobile. Certificates to high score in each county with minimum of 30 QSOs. Out of state—high out-of-state trophy and certificates for high score in each state and country.

ENTRIES:

A summary sheet is requested showing the scoring and other pertinent information, name and address in block letters, and a signed declaration that all rules and regulations have been observed. MI stations include club name for combined club score. Party contacts do not count toward the MI Achievement Award unless one fact about MI is communicated. Members of the MI Week QSO Party Committee are not eligible for individual awards. Decisions of the contest committee are final. Results will be final on July 31 and will be mailed to all entries. Mailing deadline is June 30, 1979, to: Mark Shaw K8ED, 3810 Woodman, Troy MI 48084.

ACHIEVEMENT CERTIFICATES

1979 will be the 21st year that hams have had their own program to publicize Michigan and its products. Just as for the past 20 years, the Governor will award Achievement Certificates to hams who take an active part in telling the world of Michigan's unlimited resources, opportunities, and advantages.

Certificates are awarded on the following basis:

1) A MI ham submits log information and names and addresses (if possible) of 15 or more contacts made to out-of-state or DX hams with information regarding MI.

2) An out-of-state ham, including Canada, submits log information and names and addresses (if possible) of at least 5 MI hams who relate facts to him about MI.

3) A foreign ham, excluding any resident of Canada, submits the call letters and name/address plus log information for at least 1 MI ham who has told him about MI.

4) Only QSOs made during MI Week, May 19-26, will be considered valid!

All applications for certificates must be postmarked by July 1 and mailed to Governor William Milliken, Lansing MI 48902.

For your information, the state bird = robin, fish = trout, flower = apple blossom, state tree = white pine, stone = Petoskey Stone.

PERSONAL COMMUNICATIONS ESSAY COMPETITION

The Personal Communications Foundation is pleased to announce its 1979 law student essay competition.

Any person who is a student in good standing at an ABA-accredited law school on February 15, 1979, is eligible to participate. Prizes of $500, $250, and $100 are being offered. In addition, the Foundation will endeavor to have the winning essays published in a national bar journal.

The general subject matter of the essay must deal with one or more of the legal aspects of personal communications by use of amateur radio, Citizens Band radio, monitors, and/or radar detectors. Within this area, suggested topics include, but are not limited to, constitutional issues, federal v. state and local regulation, effects upon property use and values, zoning and land-use considerations, and civil and/or criminal liabilities in connection with equipment operation (exclusive of FCC proceedings).

Essays may be of any length. They must be typed, double-spaced. Footnotes must appear at the end of the essay and conform to the current edition of *A Uniform System of Citation* published by Harvard Law Review Association.

All essays must be received

at the offices of the Personal Communications Foundation on or before October 1, 1979. Contestants must include, in addition to their name, mailing address, and telephone number, the name and address of their law school. Essays will be returned only if they are accompanied by a self-addressed, stamped envelope.

All entries will be judged by a committee of the Board of Trustees of the Foundation. The decision of the judges is final, and all entries will become the property of the Foundation. Winners will be announced no later than November 30, 1979.

The Personal Communications Foundation is a nonprofit California corporation dedicated to the collection and dissemination of legal research and information concerning personal communications. Its Board of Trustees is composed of lawyers, judges, and law-school professors who are licensed amateur radio and/or Citizens Band operators. Inquiries and essays should be addressed to Kenneth S. Wideitz, President, Personal Communications Foundation, 10960 Wilshire Boulevard, Suite 1504, Los Angeles, California 90024. Telephone (213)-478-1749.

THE SASQUATCH AWARD

Sponsored by the Chilliwack Amateur Radio Club, the requirements are as follows: Eyeball contact with one Sasquatch, radio contact with two Sasquatch. Canadian and Continental US work six amateurs in the Chilliwack District, of whom three shall be club members. DX stations work five contacts, of which two shall be club members. Use all bands and all modes with all contacts made after March 1, 1979. The cost is $1.00 for VE/W, 3 IRCs for DX. Send log data only, QSLs not required. Apply to: Chilliwack Amateur Radio Club, c/o 317 Marshall Avenue, Chilliwack, BC, Canada V2P 3J5.

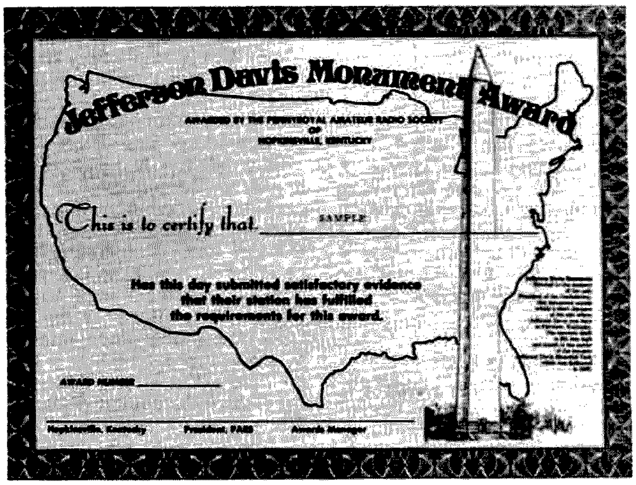
Chilliwack ARC Members: VE7s—AFA, AHN, AIO, AKD, AND, BEN, BHG, BYU, BZY, EWO, EX, FK, NHF, PU, QN, RS, TL, ZI. Local Area Calls (VE7s)—AGZ, AYZ, BBV, BDH, BIF, BLB, BPW, CBQ, CIO, CIW, CIX, CQO, GM.

JEFFERSON DAVIS MONUMENT AWARD

The Pennyroyal Amateur Radio Society of Hopkinsville KY will be operating portable from the Jefferson Davis Memorial Park on June 3, 1979, from 0001 to 2359 GMT. This certified sequential award will be issued to any station presenting written confirmation of contact with a PARS member during the QSO period, or any ten Kentucky amateurs during the year. Awards may be obtained by sending $2.00 and the QSL cards to: PARS, PO Box 1077, Hopkinsville KY 42240. The QSL cards will be returned with the award. Frequencies to be monitored are as follows: Novice—3740, 21140, 28140; General—3970, 7270, 14310, 21370, 28610.

NORTHERN LIGHTS AWARD

The Northern Lights Award is offered by the Northern Lights Chapter of the QCWA and is available only to members who are located outside the state of Alaska. Make contacts with three (3) members of the Northern Lights Chapter on any mode, any band, and any time after November 11, 1975. This is a one-time free award! Send a list of the three confirmed contacts, giving the date and time of the contacts to the secretary: J. W. "Mac" McQueen KL7AVX, 1928 East Dimond Blvd., Anchorage AK 99507.



NOVICE WAS NET FORMING!

For anyone interested, a Novice WAS net is forming at 1400 GMT on Saturday mornings on 21.125 MHz. Net control stations are KA8AKL and WD8RUH. Check in with QTH and state(s) needed. Listen for QST WASN or NWASN to locate the net. For more information, contact Rick Todd KA8AKL, 14470 Basslake Rd., Newbury OH 44065.

FAR SCHOLARSHIPS

The Foundation for Amateur Radio, Inc., a nonprofit organization with its headquarters in Washington DC, announces its intent to award six scholarships for the academic year 1979-80. All amateurs holding a license of at least the FCC General Class or equivalent can compete for one or more of the awards if they plan to pursue a full-time course of studies beyond high school and are enrolled in or have been accepted for enrollment in an accredited university, college, or technical school. The scholarship awards range from $250 to $800, with preference given in some of them to residents of various areas.

Additional information and an application form can be requested by letter or postcard, postmarked prior to June 1, 1979, from: FAR Scholarships, 8101 Hampden Lane, Bethesda MD 20014.

The Foundation is devoted exclusively to promoting the interest of amateur radio and scientific, literary, and educational pursuits which advance the purposes of amateur radio.

LETTERS

it 50 others would follow suit . . . for what? People who subscribe to QST *get their money's worth in the magazine. If they are sending in the money to buy representation, then I think they are getting cheated. Sure,* QST *could be better . . . but it's certainly worth the subscription price, even at the new rate of $18 per year . . . which is about time.*

If there are any 73 loyalists reading this, go soak your head. If there are any ARRL loyalists, go soak your head and leave it under.—Wayne.

THE HP3422

John M. Murray W1BNN
4 Kenwood Circle
Bloomfield CT 06002

Dear Mr. Murray,

I enjoyed your article in the January, 1979, edition of *73 Magazine* concerning the ship that sank off Haiti.

I have spent the last 3 years with the United States Coast Guard in San Juan, Puerto Rico, where I worked in communications and the Rescue Coordination Center (RCC). We handle approximately five hundred separate search and rescue cases each year under the direct control of the San Juan RCC. I do, however, remember the case of the HP3422, because of the part amateur radio played in saving these people's lives, and because I was on duty at the time of the incident and recall some of the procedures used.

The initial call for assistance was copied by an amateur radio operator in the States, who in turn notified the Coast Guard. Because time is usually a very important factor in rescue cases, the Coast Guard attempts to talk directly to the unit for locating, assisting, and other instructions, rather than using the longer and not-so-efficient relay method. Although we do have a number of club and personal amateur radio stations, in an emergency situation the FCC has allowed us to use any frequency with the distress unit providing it does not cause a problem with the defense of our country. In this particular case, the Coast Guard Communications Station, Portsmouth VA, was our initial radio unit in contact with the vessel. The Coast Guard has several teletype and telephone networks set up between the Navy, Air Force, other Coast Guard units, and civilian organizations in order to help perform our missions.

During this case, many different military organizations were used in the attempt to get assistance to this vessel. The Navy assisted with the direction-finding work, which they supplied to the rescue aircraft (to get it within 1 mile of vessel), the Air Force helped with aircraft, and the Coast Guard provided the major coordination and communications effort. So you see, even though it seemed that only one or two people were trying to get assistance and rescue these people, several different groups, in-

cluding amateur radio operators, played an important part in the case.

I will not go into any more details concerning this incident, because my memory and the facts might tend to differ with each other. However, for your information, the people were picked up by a passing merchant vessel diverted to the scene to assist.

James C. Norton WD8EAI
Cleveland OH

NOTHING PERSONAL

I like your magazine very much. It is probably the best ham publication on the market today! BUT... it's not worth $15 a year to me. The last time I subscribed, I got a three-year subscription for that amount.

I know what you are going to say. You're going to tell me how inflation has made the price go up and all that jazz. Well, that may be. I can't, however, keep paying what I believe to be an outrageous price. I'm sorry, OM, nothing personal.

Clay Welsh W1PI
Springfield MA

VLF RECEPTION

I very much appreciated your fine editorial on Sam Harris. I had the W8FKC call from about 1948 to 1968 and knew Sam when he was at Brush Development in Cleveland and lived in Burton, Ohio. I used to work him on 144 and 220 from my former homes in Hudson and Chagrin Falls, Ohio, when the bands were dull. I built several paramps based on his designs and used them for moontracking the very first series of Ranger moon probes with a 28' dish. In fact, the paramp designs were the basis for my being interviewed for a position at Arecibo by Dr. Drake and others up at Cornell back in about 1964-65. I didn't get the job, which is just as well, because I did not really have enough expertise at the time. However, I was also on a year's leave of absence from OU here in 1966-67 with a position as station manager of the mm-wave dish supported by NRAO out at Kitt Peak AZ. I also spent a summer at Greenbank WV. All this was due in part to my interest and ability in VHF microwaves as a result of Sam Harris' work on low-noise amplifiers, etc., so I feel Sam had some influence over my career. I have graduated to the dc-to-500-kHz range now, teaching audio methods, supervising EE senior labs, and doing contract research on various NASA-, Signal Corps-, USCG-, and FAA-supported grants and contracts.

I enjoy reading 73 very much, although sometimes the quality of the technical work is not too good. A case in point was a recent article regarding VLF signal reception. In his article about a simple VLF converter (*73 Magazine*, January, 1979), W3QVZ mentioned the use of a 1000-foot (300-meter) longwire for WWVB, and only obtaining an estimated 20 uV at the input terminal. In theory, the 13-kW erp from WWVB at 60 kHz will develop a field intensity of about 100 uV/meter at W3QVZ's QTH in Woodbine, Maryland (see NBS Special Publication #432). Now, does this tell us that a 300-meter longwire strung out over the landscape only has an *effective height* of about 20/100 meters or *only 20 cm*? This, in fact, might be approximately true considering the input attenuation involved and the inherent difficulty of making accurate signal-strength estimates with a longwire antenna at VLF.

A longwire antenna system is just not the way to go at VLF. The antenna looks more like an extended groundwire, with much more capacitance to the variable noisy ground currents flowing in the earth than effective capacitance to the electric field above. Thus, the wire is picking up orders-of-magnitude more ground noise than signal. W3QVZ's comment that the antenna leaves much to be desired, even when used with a tuned circuit, is very true.

There is a much better approach to this problem of VLF signal reception. A 3-meter-or-so vertical whip antenna mounted up as high as possible and reasonably in the clear, with low capacitance to ground (but with a very good ground system at the receiver and underneath the antenna), can provide an effective height of 20 to 60 cm. In Ohio, I can receive WWVB 60 kHz with an estimated 150 uV/meter field intensity as developed on a $2\frac{3}{4}$-meter standard CB-type vertical whip. In order to operate a vertical, it is usually necessary to have a unity-voltage-gain, high-input-impedance circuit at the antenna base.

In my case, a preamplifier related to that presented in 73 *Magazine* (May, 1978, pp. 146-153), has a measured input capacitance of 85 pF with no antenna connected. The $2\frac{3}{4}$-meter vertical has a capacitance of about 100 pF. The effective height is very roughly 100/(85 + 100) meters, or about 60 cm. I actually estimate about 90 uV for WWVB at the antenna terminal. If 90 uV is developed on an antenna with an effective height of 60 cm, then 100 cm (or a 1-meter theoretically perfect antenna) would develop about 150 uV. This approximately checks out with what WWVB says their 60-kHz signal level should be at my location in Ohio. The point to make here is that *3 meters up and vertical in the clear is better than 300 meters long over the bush.*

There are a multitude of other problems connected with operating vertical whip antennas, but they can be solved. In fact, these types of vertical antennas are now being used in military and marine VLF monitor systems for radio navigation throughout the world. The biggest single problem with all VLF E-field antennas is providing a really good ground system and relatively low capacitance to ground at the antenna terminal. In VLF reception, we are trying to measure the potential difference between what we think is our local ground system and an ideal probe sticking out into free space. A long horizontal wire does not solve the problem.

Another way of measuring antenna performance is to compare the actual height (or length) with the effective height. Thus the $2\frac{3}{4}$-meter vertical has an efficiency of [60 cm/(2.75 x 100 cm)](100) = 22%, and the 300-meter longwire has an efficiency of [20 cm/(300 x 100 cm)](100) = 0.07%, assuming all our measurements are correct. Even if we are off by a factor of ten, the short vertical antenna is still better!

Still another way of looking at the problem of a 300-meter longwire is to consider the height above ground. In the W3QVZ case, it was 60 feet, or about 20 meters, off the ground. The lead-in from this longwire may be a more effective antenna than the 300 meters of longwire. The horizontal wire adds so much capacitance directly to a noisy ground plane that it is degrading the performance of the height above ground. A good rule to follow in designing a "flattop" horizontal wire is to make the length about equal to the height and to place a buried counterpoise of radial wires in the ground underneath the whole antenna to provide a good earth ground. This is typically the type of antenna used for transmitting radio navigation beacons in the 150-kHz to 400-kHz range with a height and width of 15 to 20 meters. While the radiation efficiency is low for transmitting at these frequencies because of the very long wavelength, the receiving efficiency can be quite high in terms of effective height when used with a low-noise, high-input-impedance antenna coupler circuit.

An attempt at illustrating the problem of a longwire antenna with a low height-to-length ratio (as compared with a short vertical whip) is shown in Fig. 1. The downward point lines indicate the predominant coupling to the ground plane, and the dotted lines pointing upward show the coupling to the free-space electric field. In real-world antennas at low frequencies, it is often necessary to make a series of two-dimensional electrolytic tank experiments and plot the field contours by applying dc potential between an upper electrode and the bottom ground plane electrode containing the model antenna. The results are difficult to illustrate in two dimensions. Fig. 1 is a rough pictorial representation of the situation, not to any scale, to illustrate the idea of effective height (which is a purely mathematical concept). The main point we are trying to illustrate with all this is that it is important to have the probe (antenna)

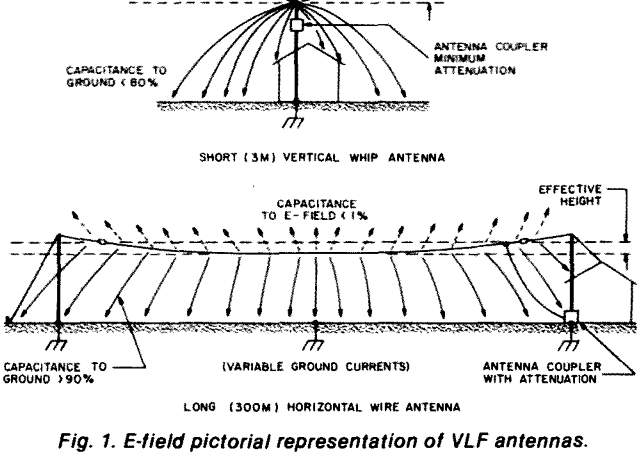

Fig. 1. E-field pictorial representation of VLF antennas.

out in the electric field as high as possible to minimize parallel capacitance and coupling to the local ground plane. In amateur work with VLF antennas, we should stop thinking about the way antennas work at 80 meters and up. Virtually all VLF E-field antennas are much shorter than a quarter wavelength. We should consider the antenna as more like placing a high-impedance probe at the end of a cable connected to an oscilloscope, with the high-Z circuitry at the antenna designed to minimize undesired noise pickup. (H-field loop antennas are a whole different story at VLF, suitable for some other author to present.)

Another aspect of W3QVZ's article on the VLF converter is the trouble experienced with cross-modulation. The use of an LM318 bipolar IC as a wideband input stage amplifier is prone to this problem. The input circuit, low-pass filter, and the input 10k summing resistor used with the LM318 operate as an attenuator for low-level signals. This decreases the signal even before it is amplified. It is not common practice to use operational amplifier methods at the very first input stage of a communications receiver. The signal-to-noise ratio is always decreased whenever an attenuation network is inserted between the source and the amplifier. A better input stage amplifier is a JFET MPF102 or 2N5457, each of which is much less susceptible to cross-modulation problems.

Good DX-hunting on VLF!

227 MOD

As a member of Army MARS, I am grateful to KH6JMU for his work on expanding the frequency range of the Yaesu FT-227R Memorizer to include some MARS coverage (*73*, March, 1979).

Following his instructions, I removed the red wire from pin 3 and the blue wire from pin 7 on Q712 (MC14028B), located on the PLL control board (PB-1773A), and soldered them to a nearby ground. I found that the display became functional from 142.000 MHz to 149.995 MHz, as he indicated it would. The unit would transmit out-of-band below 144.000 MHz, but not above 147.995 MHz—which is required to work our local Army MARS repeater (148.01 in, 143.99 out).

After studying the diagram on page 19 of the owner's manual, I noted that although Q712 controls the low-end cutoff, Q711 (MC14081B) controls the high-end cutoff which must be overridden in order to transmit above 147.995 MHz.

The "fix" is very simple. All that is required is to cut a 1/16-inch gap in the foil leading from pin 10 on Q711 to D701, allowing Q713 to function properly above 148.000 MHz. This quick fix allows full transmit and receive functions from 142.000 to 149.995 MHz, including memory. (Would you believe 1600 channels?!)

Perhaps this 15-minute modification will make the FT-227R attractive to MARS members who were considering other alternatives.

Mike Zoruba N8AIF
North Ridgeville OH

GENERATOR IMPROVEMENT

First off, thanks to Louis Hutton K7YZZ for the translation and Sr. Mario Scarpelli I6THB for his design, "The Italian Freq Generator" (January, 1979). I would like to suggest an improvement to prevent a "race" condition. Separate pin 13 of IC X5 and add an R-S flip-flop as shown in Fig. 2. This modification forces the "load" pulse to be equal to one half of the period of the generated signal, at least 50 ns at 10 MHz. Ten different 74192s were tried in the original circuit, with poor results above 5 MHz. With the modified circuit, the output signal is not "off 1 or 2 Hz at audio" and "several hundred Hz at MHz range," but is exactly "thumbwheel switch settings" plus "one" times the "multiplier switch" plus or minus the "reference oscillator error."

I had to add an additional 5 pF to the 33-pF and 100-pF capacitors to tune down to 3.400 MHz and 1.000 MHz respectively. Again, thanks for a good design, as I now have a signal generator which tunes from 0.993 Hz to 10.000 MHz with ± 1 ppm accuracy.

Clancy Arnold W9AFV
Lawrence IN

P.S. If you change IC X20 from a 7400 to 74S00 and use 2 unused gates of it for this modification, you add nothing to the parts count and gain an increase in drive power from 15 pF at 400 Ohms to 150 pF at 93 Ohms.

MEXICAN OPERATION

First, I thought I'd let you know how much I enjoy your magazine and how much I appreciate the fact that I can buy a subscription to it in Mexico for the same price as paid by stateside subscribers.

I thought some of your readers might be interested in knowing that there is now a *possibility* that licenses may be issued to visitors to Mexico. Until recently, only Mexican citizens were permitted to hold amateur licenses, and Mexico has no

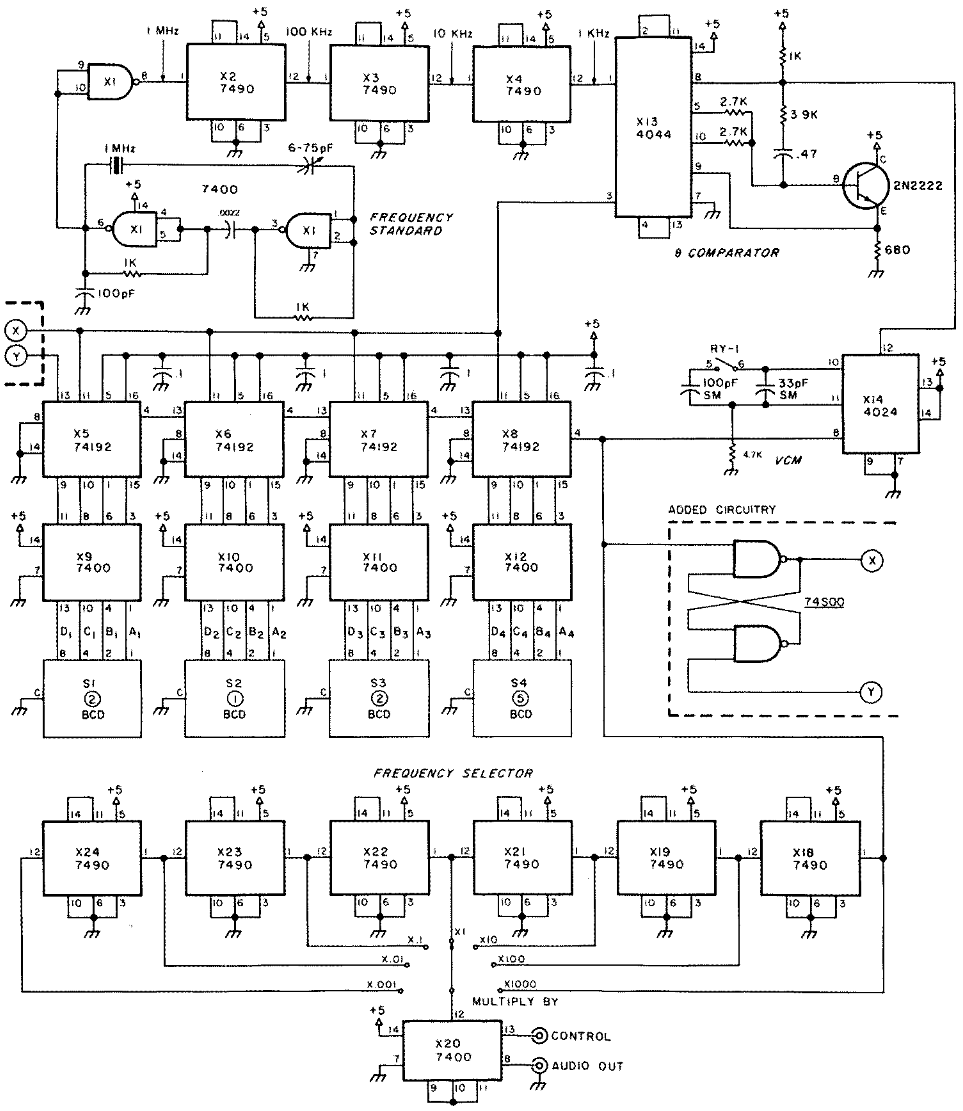

Fig. 2. Added circuitry for "The Italian Freq Generator."

reciprocal agreements in force; however, due to a change in the regulations covering amateur operation in Mexico, permits may be issued up to a term of 6 months to persons visiting Mexico.

I would suggest that anyone interested in obtaining such a permit submit a request to: Secretaria de Comunicaciones Y Transportes, Subdireccion General de Permisos Y Asuntos Internacionales, Depto. de Frequencias Radioelectricas, Oficina de Licencias, Torre Central de Telecomunicaciones, Ave. Nino Perdido Y Cumbres de Aculzingo, Mexico 12, D.F., Mexico.

I suggest that a photocopy of the current license be included, as well as a copy of the Mexican tourist card (obtainable at the airline or travel agency offices) and a statement that "In accordance with Article 19, subsection b, of title 3, Regulations to Install and Operate Amateur Radio Stations as published in the Diario Oficial of July 4, 1977," you are requesting consideration of your request to be granted a temporary permit to operate. I would also suggest that a list of places to be visited, the approximate dates, and the equipment to be brought into the country be sent at the same time.

I cannot guarantee that this will get the applicant a permit, but at least such a possibility exists, for the first time.

Kenneth M. Price XE1TIS
Irapuato, Mexico

PURE BODIES

In your editorial in the November, 1978, issue of *73*, you express concern about the effects of radar radiation absorbed as one drives down the highways of New Hampshire.

I submit that your concern is extremely parochial. You get zapped once every twenty miles or so. Consider the plight of those of us living on the heights just across the Hudson from the Big Apple—as one looks at the Empire State Building, one sees not only the TV antennas with their tremendous erp, but also all manner of dishes, yagis, corner reflectors, and horns aimed in our direction. And that is just a start—many other buildings from the Battery to uptown are also squirting a potpourri of rf our way. Of course, not all of this radiation is in the microwave region, but a good deal of it is—and many of those UHF TV channels are getting mighty close—and running lots of Watts.

I have no idea how much microwave energy I'm being subjected to, but if, as you claim, the highway dosage is 5000 times the amount of leakage allowed from microwave ovens, I'm sure I'm being subjected to a helluva lot more than that!

When you start your Church of the Pure Body, I think I'd be ready to become a convert. I'd then be able to protest the violation of my religious principles by all those rf sources across the river. Do you think we could get them to install a copper-screen rf fence along the top of our Palisades? As you say, if enough people protest, they can raise hell with the system. I don't want to move—I've lived here longer than the system has been imposing its rf on me. And the saddest part of all is that so much of the rf is being used to carry the pure unadulterated garbage that is the rule rather than the exception on the TV channels these days.

Allen L. Barnett WB2QPM
Jersey City NJ

WRIST-COM

Our January, 1979, issue contained a brief mention of a project to develop a "wrist radio" communications system. Since then, we've received an especially informative letter on the recent history of this concept. An excerpt from the letter appears below.

The conclusion one draws from your comments is that NASA was the first to conceptualize and develop a functioning two-way wrist radio. I feel that it would be more to your advantage to provide full coverage regarding the actual facts in the development of a two-way wrist radio communication system beyond the representations provided by Chester Gould.

In late 1972 and into 1973, I developed a concept and then a breadboard working model of a sophisticated two-way wrist-worn communications system for deaf-blind persons which included digital on-board control, outputting of a number of different types of messages, and Morse code capability. It also provided for signaling back to a base station in cases of an emergency. We call it the "Wrist-Com." For one version of the Wrist-Com wireless signaling system, the "Institutional Wrist-Com," we required assistance in microminiaturization, and, because of their reputation and willingness to assist, we entered into an agreement with the Technology Utilization Office of NASA which would result in their producing for us a system which was based upon our design specifications and breadboard, and which would be usable at the Helen Keller National Center for Deaf-Blind Youths and Adults by our staff and clients, and elsewhere. More than four years have gone by since the original commitment was made, and NASA is still working on the project. (Since the original agreement, I have served as a technical consultant to NASA.)

I am quite disappointed that reports such as those occurring in *Microwave Systems News* and *73* should give so much publicity to a device which is merely an artist's conceptualization, when an actual system specifically designed to make use of a sophisticated two-way wrist radio and capable of satisfying many of the survival and signaling needs of severely handicapped people is presently being prototyped. Moreover, the prototype work is based on my designs developed here at the Helen Keller National Center. In light of the above, credit for the initial development of a practical two-way wrist communication system should be given to the Helen Keller National Center for Deaf-Blind Youths and Adults.

Frederick M. Kruger, Ph.D.
K2LDC

Helen Keller National Center
Sands Point NY

Thanks for providing us with the proper background on the Wrist-Com idea. Best of luck with the project, Fred, and be sure to keep us up to date on your progress.—Jeff DeTray WB8BTH/1, Assistant Publisher.

HAD IT

I enlisted in the Navy in 1956, and ended up as a Radioman. In 1962, while on my one and only tour of shore duty, I was stationed with several amateurs, and a friend of mine had quite a collection of back issues of *CQ* and *QST*. I spent a lot of time reading and enjoying these old magazines, especially "Never Say Die" and "Scratchi." So, I went and got a General class license.

I spent many enjoyable hours working 20 CW from the small ham shack where I had the misfortune to be stationed. I ended up with a big bunch of QSL cards (all of which were acknowledged), and then went to a ship home-ported in a country without reciprocal privileges.

About this time, the subscription to *CQ* I had ordered finally caught up to me. Right away I opened it to W2NSD, only to find out it wasn't there; no Scratchi, either. Then I saw an editorial by the new editor, and the part that sticks in my memory after 15 years was something he wrote to the effect that there is no place in a ham magazine for levity. And that was why Wayne Green was no longer the editor. The next ten issues were passed on to my ham shipmates without being opened. Naturally, I never renewed that subscription.

At the same time, I let my membership in the ARRL lapse, mainly because of incentive licensing. I didn't mind working harder for something more, but it really ticked me off to lose what I already had.

In 1966, I became a submarine sailor. No chance for amateur radio there, but each time my license expired, I renewed it, thinking that one day I would be on the air again. In the meantime, I had tours on four submarines, in Viet Nam, and in Taiwan. Finally, in 1976, I retired from the Navy. During my career, I had been the leading Radioman in five different radio shacks, and only a Navy Radioman can tell you what that means to a Radioman. I had also managed to acquire a First Class Radiotelegraph license, and shortly after retiring, I received my Merchant Marine Radio Officer's license and Z-card. I did not, however, attempt to upgrade my amateur license, mostly because of a lack of interest.

Shortly after I retired, I received your offer of a three-year subscription at a special price, and I went for it. The first couple of issues got me thinking again, and over the past couple of years I have been doing quite a bit of soul-searching and discussing amateur communications with some of the amateurs I know.

I have now reached the conclusion that after twenty years as a professional radio communicator, I've had it. Amateurs today are the same as they were when I started. If you manage to get in contact with one of them, either they are looking for as many contacts as possible or, if they are interested in communicating (rag chewing), which is my bag, it seems like all they can talk about is what gear they are using. The fact that I can receive them at all tells me that they have an antenna, a transmitter, and some sort of electricity hooked up to it. If I ask about the weather, they don't know because they haven't been outside of the ham shack for the past week. If I ask about the liberty where they are, such as the night spots, local attractions, etc., the contact either fades, or the other guy comes on like the caretaker at the local monastery.

Well, now I have a job as a locomotive engineer. (That's the guy who runs the train.) I have a radio on my engine but I

couldn't tell you what frequency it's on. I suspect it's around 160 MHz, on FM, but if it isn't, I'm not concerned. As a matter of fact, I'm not really all that concerned about whether it works or not. And that's the limit of my two-way communications.

If, as you fear, WARC takes away the amateur frequencies, I'm not going to mourn them. If I haven't made it clear why not, I'll spell it out here: incentive licensing. Once it went in, I went out and have stayed out.

Well, Wayne, I know this is the type of letter you don't like to receive, but it is how I feel. If you want to cancel my subscription now, that's okay. If not, I'll keep reading the magazines as they come until it runs out, but I won't be renewing it.

OUT OF SIGHT

I have just returned from an ARRL convention/hamfest, where I attended an ARMA (Amateur Radio Manufacturer's Association) meeting at which most of the ARRL board of directors also sat in. Since ARMA allows manufacturers, dealers, reps, and publishers to be members, the ARRL was classified as a publisher and allowed to participate in the meeting. The meeting started with just a handful of manufacturers and dealers and the group of ARRL directors. The first words that came from the ARMA meeting moderator were, "It has been said that ARMA is anti-ARRL—this is not so." With that, you could hear a sigh of relief in the form of a wheeze from the elderly ARRL board members. The main topic of the meeting was the 220 band and what to do with it. They also talked about the 10 meter amplifier ban.

As some of you know, the ARRL has asked the FCC to allow the use of 220 for the Novice for phone, hoping to bring more users to the band. ARMA wants to start an all-new entry level exam for 220, with a code recognition test (3 to 5 wpm) and a Novice-type technical exam. The testing for the new class would be much like the Novice test, only the old term "Novice" would not be used. After all, who wants to be a novice at anything? The term "Communicator" will not be used either. They said that "communicator" sounds too much like CB and that the high emotional feeling of hams about that word would spell doom for the ARMA plan. So they have to come up with a name that all will go for.

ARMA then disclosed its plan of attack. It called for $30,000 to go for a lobbyist to push a $1.5 million FCC grant/funding pool for the "new class" license. ARMA said that the FCC had told them that if the money were appropriated, the new class could be on the air by midsummer of '79. With that came the big question—Will the ARRL back ARMA and their plan? Silence fell over the room. ARMA members were on the edge of their chairs, and all you could hear were the tapping of toes, the counting of fingers, and the scratching of heads coming from the ARRL leaders. Then came the big answer: Well, maybe, but off the record—we don't want to make anyone in the "fraternity" mad at us and lose members.

It seemed to me that the ARRL directors were looking after themselves as board members, but as elected representatives they were not doing their job in any way. Even the next day, at the ARRL membership meeting, the ARMA plan was not brought to light to the membership. If a phrase could be used to express the ARRL feelings on any issue that might have an impact on membership, it's "out of sight, out of mind."

PART 97—AMATEUR RADIO SERVICE

Editorial Amendment Concerning Application for Station License

AGENCY: Federal Communications Commission.

ACTION: Correction of final rule.

SUMMARY: FCC amends rule to correct error in paragraph sequence.

EFFECTIVE DATE: March 13, 1979.

ADDRESSES: Federal Communications Commission, Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT:

Upton Guthery, Office of General Counsel, 202-632-6444.

In the matter of editorial amendment of § 97.41 Rules of Practice and Procedure; Order.

Adopted: February 26, 1979.

Released: March 2, 1979.

1. To correct inconsistencies between the amendatory language and the paragraphing of the rule changes in two orders amending § 97.41 of the Rules, we are issuing this order specifying the correct text of that section. The orders in question are FCC 78-76, 43 FR 7323, February 22, 1978, and FCC 78-210, 43 FR 15331, April 12, 1978.

2. Authority for this action is contained in Sections 4(i) and 303(r) of the Communications Act of 1934, as amended, 47 U.S.C. 154(i) and 303(r), and § 0.261(d) of the Rules, 47 CFR 0.261(d). Because the correction is editorial in nature, compliance with the prior notice and effective date provisions of 5 U.S.C. 553 is unnecessary.

3. Accordingly, it is ordered, effective March 13, 1979, That § 97.41 is corrected to read as set forth below.

(Secs. 4, 303, 48 Stat., as amended, 1066, 1082; 47 U.S.C. 154, 303.)

R. D. LICHTWARDT,
Executive Director.

In part 97 of Chapter I of Title 47 of the Code of Federal Regulations, § 97.41 is corrected to read as follows:

§ 97.41 Application for station license.

(a) Each application for a club or military recreation station license in the Amateur Radio Service shall be made on the FCC Form 610-B. Each application for any other amateur radio license shall be made on the FCC Form 610.

(b) One application and all papers incorporated therein and made a part thereof shall be submitted for each amateur station license. If the application is only for a station license, it shall be filed directly with the Commission's Gettysburg, Pennsylvania office. If the application also contains an application for any class of amateur operator license, it shall be filed in accordance with the provisions of § 97.11.

(c) Each applicant in the Safety and Special Radio Services (1) for modification of a station license involving a site change or a substantial increase in tower height or (2) for a license for a new station must, before commencing construction, supply the environmental information, where required, and must follow the procedure prescribed by Subpart I of Part I of this chapter (§§ 1.1301 through 1.1319) unless Commission action authorizing such construction would be a minor action with the meaning of Subpart I of Part I.

PART 97—AMATEUR RADIO SERVICE

Extending Grace Period for Renewal of an Expired Amateur Radio Service Operator License

AGENCY: Federal Communications Commission.

ACTION: Order (Rulemaking).

SUMMARY: The Amateur Radio Services rules are being amended to extend the grace period for renewal of an expired amateur radio license from one year to five years. At present, persons who do not renew within one year of the expiration of their license must be retested in telegraphy and radio theory. Extension of the grace period will reduce the number of re-examinations and/or requests for waiver of the re-examination requirement.

EFFECTIVE DATE: March 16, 1979.

ADDRESSES: Federal Communications Commission, Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT:

Mr. Stephen J. Francis, Private Radio Bureau, (202-632-7175).

SUPPLEMENTARY INFORMATION:

Adopted: February 28, 1979.

Released: March 5, 1979.

Order. In the Matter of Amendment of Part 97 to extend grace period for renewal of an expired Amateur Radio Service operator license.

1. The purpose of this Order is to amend Part 97 of the Commission's rules to lengthen the "grace" period for renewal of an expired amateur radio operator license. Section 97.13(d) of the Commission's rules now states that, "If a license is allowed to expire, application for renewal may be made during a period of grace of one year after the expiration date. During this one year period of grace, an expired license is not valid."

2. Applicants who allow the one year period of grace to expire must normally be reexamined to demonstrate again their qualifications to be amateur radio operators. The Commission, however, receives many requests for waivers of § 97.13(d) from applicants, who, for various reasons, have unknowingly permitted their licenses to lapse beyond the one year period of grace.

3. In considering whether or not to grant waivers of § 97.13(d), the Commission evaluates the circumstances surrounding the non-renewal of these licenses. The rule is waived in cases when (1) circumstances beyond the licensee's control, such as a physical disability or a death of a close family member prevent the licensee from filing a timely application and (2) the period since expiration of the "grace period" has been of brief duration. When a waiver is granted, the Commission presumes the applicant is still fully qualified to operate an amateur station.

4. It is evident from experience gained in processing several hundred requests for waivers in recent years that the overwhelming majority of requests result in waivers. For this reason, the Commission is amending § 97.13(d) to change the period of grace from one to five years. The Commission concludes that the five-year period is one in which it is reasonable to presume that the licensee will remain fully qualified. While there is no clear demarcation, we believe that an extension of this period beyond the equivalent of one additional license term is unwarranted.

5. The rule amendment will reduce Commission workload in two ways: (1) The Commission will receive fewer requests for waivers, each of which now require individual attention and handling; and (2) the Commission will administer fewer second examinations to ex-licensees who failed to renew their licenses within the "grace period".

6. Authority for these amendments is contained in Sections 4(i) and 303 of the Communications Act of 1934, as amended. The Commission finds, that for good cause the prior notice and public procedure provisions of the Administrative Procedure Act (5 U.S.C. 553) are unnecessary because the Commission believes that there would be no objection to the relief from previously imposed restrictions. Early adoption would simplify application filing requirements, accelerate the speed for processing applications, and reduce delay in eliminating restrictions.

7. *It is ordered,* That effective March 16, 1979, Part 97 of the Commission's rules and regulations is amended as set forth below.

(Secs. 4, 303, 48 Stat., as amended, 1066, 1082; (47 U.S.C. 154, 303))

FEDERAL COMMUNICATIONS COMMISSION,
WILLIAM TRICARICO,
Secretary.

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended as follows:

1. In § 97.13 paragraph (d) is revised to read as follows:

§ 97.13 Renewal or modification of operator license.

* * * * *

(d) If a license is allowed to expire, application for renewal may be made during a period of grace of five years after the expiration date. During this five year period of grace, an expired license is not valid. A license renewed during the grace period will be dated currently and will not be backdated to the date of its expiration. Application for renewal shall be submitted on FCC Form 610 and shall be accompanied by the applicant's expired license.

AMATEUR RADIO SERVICE

Terminating Proceeding Concerning Operator Classes, Privileges, and Requirements

AGENCY: Federal Communications

Commission.

ACTION: Termination of rule making proceeding.

SUMMARY: The Commission decides to defer action on the "Communicator Class" and "dual ladder" amateur licensing. A petition for "lifetime" issuance of the Amateur Extra Class license is denied; and action is deferred on changing the procedure for measuring amateur transmitter power.

EFFECTIVE DATE: Not applicable.

ADDRESSES: Federal Communications Commission, Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT:

James E. McNally, Jr., Personal Radio Division, Private Radio Bureau, (202) 632-7175.

THIRD REPORT AND ORDER—(PROCEEDING TERMINATED)

Adopted: March 6, 1979.

Released: March 14, 1979.

In the matter of amendment of Part 97 of the Commission's rules concerning operator classes, privileges, and requirements in the Amateur Radio Service, Docket No. 20282, RM-1016, 1363, 1454, 1456, 1516, 1521, 1526, 1535, 1568, 1572, 1602, 1615, 1629, 1633, 1656, 1724, 1793, 1805, 1841, 1920, 1947, 1976, 1991, 2030, 2043, 2053, 2149, 2150, 2162, 2166, 2216, 2219, 2256, 2284, 2449.

1. On December 16, 1974, the Commission issued a Notice of Proposed Rule Making in the above-entitled matter which was published in the FEDERAL REGISTER on December 20, 1974 (39 FR 44042). The major proposed rule changes contained in the Notice were the following:

(a) Creation of a 'dual ladder' licensing structure;

(b) Creation of a "Communicator Class" license having no telegraphy privileges or examination requirement;

(c) Establishment of new power limits based on transmitter peak envelope power output;

(d) New restrictions on licenses obtained by means of volunteer-administered mail examinations;

(e) Issuance of lifetime Amateur Extra Class operator licenses; and,

(f) Modification of the frequencies and modes available to certain license classes.

2. Because of severe manpower and time restrictions brought about by the huge surge in Citizens Band Radio Service applications since 1974, we were unable to undertake the preparation of a comprehensive Report and Order addressing all of the issues raised in the Notice. We did, however, release a First Report and Order on June 15, 1976 (41 FR 25013) which amended the rules to reflect the following changes:

(a) Except in cases where the applicant was physically disabled (and where the Commission would select the volunteer examiner), volunteer-administered examinations could only be given to applicants for the Novice Class license;

(b) The Conditional Class license and the "conditional" (C) limitation on the Technician Class license were to be eliminated upon renewal. Licensees holding the Conditional Class license were to be issued a regular General Class license, and holders of the Technician (C) Class license were to be issued regular Technician Class licenses;

(c) The 175 mile distance eligibility criteria for the General (formerly Conditional) Class license was eliminated;

(d) Applicants for any class of amateur license must take Element Two;

(e) Holders of the Technician Class license were given all Novice privileges; and,

(f) The maximum permissible input power for Novices was increased to 250 watts.

3. Subsequently, on April 6, 1978, we released a Second Report and Order (43 FR 15324) which gave holders of the Technician Class license full operating privileges above 50 MHz, and which changed the term of the Novice Class license from 2 years, non-renewable to 5 years, renewable.

4. The purpose of this Third Report and Order is to dispose of the remaining unresolved matters.

5. First, we have decided to take no action at this time on the 'dual ladder' licensing structure proposed in the Notice, or on the creation of a "Communicator Class" license having no telegraphy privileges or requirements. We firmly believe in the principle, articulated in the Notice, that in any licensing system there should be a logical relationship between the qualification requirements and the operator privileges authorized at each license class level. We feel that the "Communicator Class", as proposed, was in keeping with this principle; and we do not agree with the majority filing comments who asserted that the privileges to be conveyed by the "Communicator Class" were "out of proportion" to the qualification requirements. Nevertheless, since much time has elapsed since the issuance of the Notice (4 years), and since the Amateur Radio Service has grown about 50% in that time period (with many of the new licensees coming from the Citizens Band Radio Service), it is our belief that the comments, and perhaps even our original proposal, have become somewhat outdated. Then, too, tremendous growth has taken place in the citizens Band Radio Service (1400% in 4 years); and we would like to get the views of these newer licensees on the need or desirability of a "codeless" class of amateur license. Accordingly, we hope to revisit this matter later this year in a new rule making proceeding.

6. At this time, however, we will address the matter of lifetime issuance of the amateur Extra Class license (RM-2030). In the Notice, we proposed to adopt this request since our records indicated that very few amateurs drop out of amateur radio after they have attained the amateur Extra Class. We pointed out, however, that while section 303(L)(1) of the Communications Act of 1934, as amended, allows us to issue operator licenses for life, section 307(d) limits the term of the concomitantly issued station license to not more than 5 years. At best then, we would only be able to eliminate the need to retake the examination should the amateur neglect to renew his (or her) license.

7. In the years since the issuance of the Notice, however, we have become very sensitive to the adverse effects such "special case" consideration can have on our various personal (and amateur) radio service data processing systems. While we generally retain files containing information about expired licenses for periods in excess of 5 years after the expiration date, to maintain these files indefinately would be a new and burdensome requirement, particularly in view of the fact that very few people would be expected to take advantage of the lifetime non-examination renewal privilege. In a separate action, we have amended § 97.13 to extend the "grace period" for all classes of license from one to five years. This extension will accommodate a great variety of personal circumstances which has been the basis of requests for waiver of the "grace period"; and it is, in our opinion, an equitable alternative to a lifetime, non-examination renewal privilege. Accordingly, we have decided to take no additional action on this matter.

8. Lastly, the comments filed in response to our suggestion of establishing new power limits based on transmitter peak envelope power output were, in the main, negative. There were, however, several respondents who did suggest innovative alternatives to our proposal. While we have decided to take no further action on this matter at this time, we are still of the opinion that the state of present-day amateur communications warrants the use of better procedures to determine transmitter power than the "plate voltage times current" method. We intend to revisit this matter at a later time, and we encourage amateurs, in the interim, to develop and disseminate data which could be used as a basis for a workable and state-of-the-art measurement technique.

9. Accordingly, pursuant to the authority contained in Sections 4(i) and 303 of the Communications Act of 1934, as amended: *It is ordered*, That this proceeding is terminated. Further information about this action by the Commission may be obtained by contacting Mr. James E. McNally, Personal Radio Division, FCC, 1919 M St., NW., Washington, D.C. 20554 (202-632-7175).

FEDERAL COMMUNICATIONS COMMISSION,
WILLIAM J. TRICARICO,
Secretary.

OSCAR Orbits

Courtesy of AMSAT

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's *first* ascending (*northbound*) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

DX

from page 13

about evenly between CW and SSB. They were active for three weeks and operated during the CQ-WW 160 Meter Contest.

Amateur radio operators in Sweden and the U.S. will attempt direct contact between Bishop Hill, Illinois, and Biskopskulla, Uppland, Sweden, during the weekend of May 26th and 27th. Bishop Hill was a communal settlement established in the 1840s by Swedish immigrants, and is now a historical site maintained by the state of Illinois. Led by W9FKC and SM0FY, the two groups will contact as many stations as possible during the time period. Special QSLs will be issued, and SASEs are requested. QSL to WA9AQN.

The Wiesbaden Amateur Radio Club will be going on a DXpedition to Lichtenstein from 26 May to 3 June. They will be using the callsign HB0XAA. The frequencies they will be using are: 3.780, 7.090, 14.280, 21.350, 28.650 SSB, and 25 Hz up from the bottom for CW. For the Novices, some of them will try to get on at other times, but nothing is scheduled so far. The QSL manager will be Hugo Jakobljevich DJ0LC, Am Weinberg 10, 6201 Auringen.

BEATA ISLAND

The following letter from Tim HI8MFP wraps up the recent HI1RCD operation from Beata Island:

"The Beata DXpedition was a success, with more than three thousand contacts in 52 hours of operation. Fifty-three countries were contacted. The first contact took place at 2045 GMT on the 25th, and the last was made at 1234 GMT on the 28th.

"The trip on the boat to the island was excellent. We left the island six hours before the set time, on the recommendations of Navy authorities who said they were expecting changes in the water currents which would make the trip back dangerous.

"QSL information should be sent to: Beata Operation, PO Box 2191, Santo Domingo, Dominican Republic, West Indies (or via bureau: PO Box 1157, Santo Domingo, Dominican Republic). The cards are already being printed and we hope to start mailing them soon. We would like to remind all those who contacted us on the 27th to send an SAE and 3 IRCs in order to receive the first day cover.

"The prefix HI1 was activated for the first time, and now we are compiling all the information to be sent to the ARRL in order to try to qualify Beata as a new country. If this goal is achieved, the group would be willing to repeat the operation next year for a week.

"Thank you for your cooperation, and we hope you appreciate our effort."

DX NOTEBOOK

Bangladesh S2

S2BTF shows regularly on Saturdays near 14275 MHz after 1700Z.

Qatar A7

A7XAH has been showing around 14225 kHz between 1300Z and 1500Z on Fridays. This is a list operation.

Senegal 6W8

6W8HL has N1ACW as MC on 14260 kHz from 2100Z daily. At 2245Z they shift to 21275 kHz.

South Georgia VP8

VP8SU has G3KTJ and QSL manager G3RCA running the list Sundays from 1900Z to 2100Z on 14280 kHz. He also hangs around this area during the week.

Minami Torishima KA1

KA1NC regularly offers this rare one to 5BDXCC hunters at 1100Z on 3798 kHz.

Christmas Island VK9XI

This is a club station and usually is activated on meeting nights. Look for it Wednesdays around 14225 kHz after 1530Z.

Aves Island YV0AA

If you receive this magazine early, you may still be able to catch this one. The operation opens April 28th and will secure on May 1st at around 0600Z. The frequencies to watch are: 3795, 7085, 14195, 21245, 21295, and 28495 on SSB, and 25 kHz up from the bottom edge on CW. They will announce listening frequencies.

Peter Island

Willy got to Peter Island just about on schedule, but after an on-site survey, any landing attempt had to be scrubbed. Willy decided to head east through the Drake Passage and into the Atlantic. He should have passed through ZD9 in April, and present plans call for stops at PY0/Trinidad in May, possibly PY0/St. Peter-St. Paul in June, and then on to the Azores by the end of July.

48,100 QSOs IN 1978

With a last-minute spurt on December 30th and 31st which netted 540 QSOs, Dick Spenceley KV4AA wound up 1978 with a total of 48,100 contacts. This was an average of 131 per day, or one QSO every 11 minutes of 1978.

Dick KV4AA and his SSB operating position, where many of the more than 48,000 QSOs in 1978 were made.

About 65 percent of the contacts were on CW, with the balance on SSB. A total of 199 countries were worked, with only a couple of them being "chased." Assorted equipment held up nicely, as did Dick's 73-year-old health.

Continuous calling by European stations on CW (even during QSOs) and the cooperation of U.S.A. SSB ops, plus contest operations, made large totals easy. KV4AA took part in just about every contest that turned up. Otherwise, QSOs, though short, were not of the "contest" or "DXpedition" variety. This makes a difference of three QSOs per minute versus one every three minutes.

All this started in 1976, when Dick's AJ3AA bicentennial call resulted in 35,335 QSOs, or an average of 96 per day. A goal of 36,500 contacts was set for 1978—100 per day. When this was passed on October 19th, a new goal of 45,000 was set. This was met on December 14th, and another 3,100 were worked.

It is realized that certain factors are a "must" for such totals, such as a fairly "exotic" call and plenty of time. This will limit most. KV4AA was not on continuously, as he works daily until 1:00 pm. Until the latter part of the year, he was seldom on after 7:00 pm. Stations contacted twice or more often during the same day were only counted one time, unless the mode and band were different.

Invaluable aid was given the project by YASME (WA6AHF) and other West Coast hams who handled the KV4AA QSLing chores.

KV4AA's three-year total now stands at 115,280 contacts. Dick says, "This year, we rest—but 't ain't easy getting used to."

THE RUSSIAN WOODPECKER

The following report is from the *West Coast DX Bulletin* and was compiled by a W3.

"If you have not heard this one, you have not been on the air in the last year or two. Like a lot of other things, you try to live with it and wish it would go away—but it seldom does. Maybe if you know a bit more about it, it might help to tolerate the burden.

"The 'woodpecker' is a long-range radar; the range can be estimated by noticing that the repetition corresponds to 25-wpm CW dots. At this speed, the time from dot to dot is 96 milliseconds. This means that the radar range is roughly 47 million feet, or 8950 miles. This on-the-air estimate was done without instruments, so it is probably a bit in error. If the actual design range was 15,000 km, or 9320 miles, the error would be only 4%.

"Presuming a ten-million-Watt source, and 18 dBi of antenna gain, the effective radiated power, erp, is 88 dBW. However, if you figure twenty meters at 1000 miles, this immense signal is reduced by path loss to a mere .0006 of a Watt.

"This might make some think that a one-Watt jammer would have an advantage over the woodpecker of 1000:1, but this is not correct. Not all of a jamming signal will be effective unless it is able to pass through the i-f and video filters of the radar. A constant carrier is not effective at all, because it is rejected as a dc signal by the ac-coupled video circuitry of the radar.

"However, CW dots will get through. Assuming a rise time of one millisecond for amateur CW, an additional 20-dB advantage is given back to the radar because of the mismatch in rise time, video bandwidth, and corner frequency. Notice that the CW dot jammer, even if only using one Watt, still has a 10:1 ad-

vantage. A 100-Watt or a 1000-Watt signal would be even better.

"There is some reason to believe that much of the above is true. For one thing, the woodpecker is only heard on the phone bands, where voice envelopes can be rejected by the radar video circuitry. Also, if someone is sending CW dots at 25 wpm, the woodpecker usually shifts frequency within five minutes.

"Some have noted that continuous 25-wpm CW dots on the woodpecker's frequency have caused them to stop transmitting—one time, for a period of three weeks. The woodpecker then returned with a new gimmick. When problems developed, the woodpecker would switch to another frequency on the amateur band."

This seems very interesting, and while we sure aren't advocating intentional jamming, it would be interesting to experiment around with. The problem is, we aren't sure which would be worse, the woodpecker or a bunch of endless CW dots at 25 wpm.

New Products

from page 26

but also allows the internal speaker to remain unmuted.

The Communicator II has incorporated a novel mounting bracket which allows forward and backward slide adjustment to accommodate virtually any mobile mounting position. The transceiver mount mates with the mounting bracket slides and the unit is secured in place with two quick-turn knobs. Also included with the Communicator II is a desk-top bracket which snaps in place to elevate the front of the unit for indoor use.

A 24-pin accessory connector is mounted on the rear of the transceiver. Five connections are factory wired: PTT, ground, af input, af output, and 13.8 V. These will allow easy installation of TT, phone patch, or subaudible tones. The nineteen unconnected pins allow individualistic modification without case damage.

The Communicator II, priced at $399.00, carries a dealer-backed, factory warranty of one full year. *Pathcom, Inc., Amateur Radio Products Group, 24105 South Frampton Ave., Harbor City CA 90710.*

A GREAT NEW HAND-HELD FROM HEATH

The amateur market is crowded with two meter rigs, yet I had been having problems finding one that would fit the budget of a high-school student. Then one day a new Heathkit catalog appeared in my mailbox. Glancing through the catalog, I found just what I had been seeking: Heath had come out with a new hand-held called the VF-2031. I was not only impressed with it, but also I could afford it.

Before I was to purchase it, however, there were two problems that had to be resolved. First of all, I had heard complaints from owners of Heath's previous hand-held, the HW-2021, which was recently discontinued. It seems that the 2021 had many design problems. Was the VF-2031 going to have gremlins also? After some reflection, I rationalized that Heath most likely had received much feedback on the previous rig's problems, and planned to eliminate similar problems from the VF-2031. The second thing that had me concerned was a notice in the catalog at the bottom of the rig's description. This little blurb stated that the kit was not recommended for beginning kit-builders. Although I had previously built several Heathkits, I was certainly not in the running for the "Kit-Builder's Hall of Fame." I finally decided that if I was to become experienced in electronics, this would be a good test of my ability. Besides, in the back of mind, I *knew* that I could do it. Subsequently, I decided to buy the kit.

Two weeks after ordering, my kit arrived. After opening the carton, the first thing that had to be done was to make several changes in the assembly manual as directed by a correction sheet. After this was completed, I glanced through the manual to become familiar with the construction of my hand-held. Heathkit manuals are a pleasure to read; every step is laid out in a clear, precise manner. There is even a separate book of diagrams so that one need not constantly flip between pages in the manual. Heath also provides various goodies to aid in kit construction: solder, desoldering braid, nut drivers, and alignment tools. The only tool that I did not have for construction of the kit was a pair of wire strippers. Although they are not necessary, past experience told me that these devices are very useful; I also feared that if I continued to strip wires with my teeth, I would become a Leon Spinks look-alike. A quick trip to the house of a friend (Mike WB7ECW) netted me a pair of wire strippers.

Construction

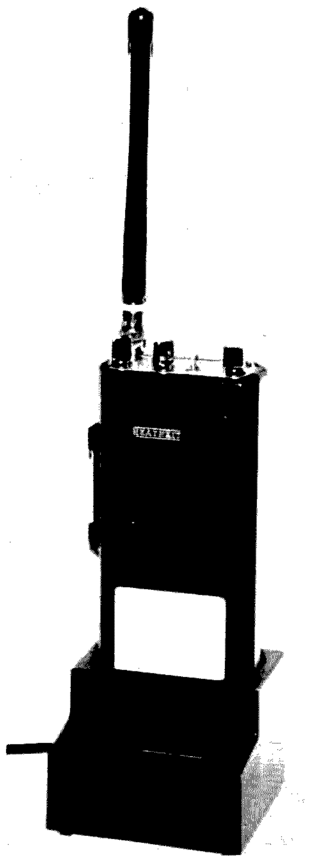
After putting aside the drop-in charger that was built in almost no time at all, I was ready to start the construction of the hand-held. Glancing at the printed circuit board, I realized that I would have to be careful while installing parts; the board is very crowded and things could become a bit rough if I had to remove a component that was tightly surrounded by others.

Since the board was compact, most components were mounted vertically. There was no room for Heath to put component values or numbers on the board, but what they did do, however, was put different symbols on the board for the components. A darkened-in circle, for example, was the symbol for a resistor. In this way, one could tell the relative positions of the components on the board.

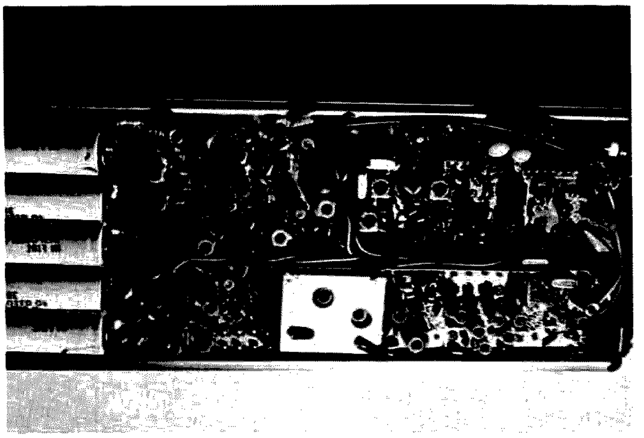
Be careful of component placement with this method, as it can easily lead to confusion. At the time, however, I felt that I couldn't possibly install a component incorrectly. It was because of this attitude that a replacement choke had to be ordered. I was trying to remove a choke that was installed in the wrong spot (it seemed as good a spot as any after several hours of work) and, much to my dismay, I removed a lead from the choke at the same time. This wasn't enough for me, however, as I ended up breaking the glass body of a diode while making room for a capacitor that was to be installed. Moral of the story: Take frequent breaks and do not rush through the construction of any electronic kit.

Another thing that I had to be careful about was component values. Poor lighting can raise havoc with one's eyes, so I made sure that there was enough light so as to not strain

Photos by Scott Rumbaugh



The VF-2031 as it sits in its charger.



Circuit board close-up. Note that the PC board is double-sided.

my eyes. It is very difficult to read the color code of a resistor if the only source of illumination in the room is a desk lamp in the corner of the workbench. Also, a 2.2 pF capacitor looked very much like one of the 22 pF capacitors, as the decimal point was very faint. A similar problem arises with the small glass-bodied diodes; the bands are hard to see. If in doubt, one should use the magnifying glass that Heath encloses.

The printed circuit board is divided into six sections. After one section is completed, it is then time to move on to the next section. Heath provides some hints that might eliminate much misery. They suggest that one should take breaks and inspect each section after completion. These warnings make the kit sound as if it is very difficult to build, however, which it is not. I found the PC board construction to be fairly simple; it wasn't nearly as hard as I had expected. The hardest part of the kit was wiring. I had to be careful that my soldering iron didn't burn any insulation from adjacent wires while I was soldering. This was especially true with the switch wiring, which was fairly tight and constituted the hardest part of construction.

Alignment

After a week of hibernation in my workshop (i.e., bedroom), the construction of the hand-held was complete. At this point, I brought out my trusty ol' VOM to make the resistance measurements. Everything checked out fine; at least my rig wasn't going to go up in smoke when power was applied. I was now ready to proceed and align the rig.

Alignment procedures have always been the worst part of kit construction for me. It is always frustrating to adjust one coil and then have to go back and readjust another coil, repeating this process over and over. I was afraid that the six pages of alignment steps were going to take longer to complete than the actual construction of the rig. As it turned out, these steps were completed in a couple hours and were not very difficult.

The only piece of test equipment needed for alignment is a VOM, an instrument that almost every ham owns or at least has access to. Rf signal generators, deviation meters, frequency counters, and wattmeters are other instruments that are helpful, but they are not required for alignment.

Several test points on the circuit board simplify the alignment procedure. All I had to do was hook my voltmeter to these test points and use the alignment tool to adjust the circuit coils for a peak or dip reading on the meter. The only rough spot in alignment that I encountered was with the receiver front end. The voltmeter readings hardly varied at all as I tried to peak the coils. If I had had an rf generator, things would have been a lot easier. I then remembered that I had a portable VHF receiver. I tuned this receiver 10.7 MHz below the hand-held's receive frequency. The VHF receiver's circuits put out a hefty signal that could be picked up on my hand-held. Voila! I now have an rf signal generator.

I then adjusted the transmitter section, getting a little more than two Watts output power. The deviation potentiometer was set to midrange because I didn't have a deviation meter. Later, I fine-tuned this control while on the air.

The final alignment step was to get the hand-held exactly on frequency. I borrowed a frequency counter from my electronics teacher, since the alignment without a counter involved more work than with one. In other words, I'm lazy! I quickly adjusted the trimmer inductors for each installed crystal. Now that the construction of my hand-held was complete, I was on the air.

Operation

As soon as I put the transceiver on the air, I began to get excellent signal reports. The audio was good and I was getting into the repeater fine. Needless to say, it was good for my ego to have the rig work well. A day or two later, however, I ran into a problem. WB7NML had given me a call on the local repeater; when I answered, he didn't respond. I called him again, but he again did not reply. He then cleared and I noticed that the receiver was "motorboating." I then realized the problem: Nicads don't stay charged forever. The nicads in the VF-2031 last about ten hours on a charge, and on the previous night I had forgotten to place the transceiver in its charger.

Conclusion

The VF-2031 has many features that have made it worth more than the $190 that Heath asks for it, including:

- eight channel capability
- 146.94 MHz crystal
- only one crystal per channel is used; one crystal renders one receive and three (−600 kHz, simplex, +600 kHz) transmit frequencies
- separate microphone and speaker built in
- BNC antenna jack
- battery-saving squelch circuit
- earphone
- many available accessories (external microphone, continuous tone encoder, autopatch encoder, amplifier, and holster-type carrying case)

As demonstrated by the above features and the quality of the rig, it is obvious Heath has come out with a winner—the VF-2031.

Corvallis OR

THE MIDLAND 13-510—A USER REVIEW

For quite some time, I have been wanting and trying to get active on two meter FM. It wasn't until just recently that I found myself in a position to make the big jump and purchase that two meter rig. Wanting to get the most rig for the amount of money spent, I did a lot of studying in past issues of *73 Magazine* to see if anyone had ever reviewed the various pieces of two meter mobile rigs and, if so, what they had to say about them. At first, as many articles were published on adding channels to the Icom IC-22S, I thought that this would be an easy rig to work with. Then the many various ham outlet stores started to have their year-end sales. The prices looked better with each issue of *73*. Finally, I made the big jump and called one of the leading stores. They were all out of the IC-22S, as well as most of the crystal-controlled rigs. I also noticed in their advertisement that the Midland synthesized model 13-510 was being listed at $100.00 below suggested retail. Luck of the poor be with me, they had one. So I made the choice, and I believe that I made a very wise choice. I anxiously awaited the UPS truck; after five days, I received the Midland. As I opened the box and pulled out the transceiver, I noticed how everything was carefully packed. I started reading the instruction book and found it to be very straightforward. In no time whatever, I had the rig installed and operating.

A check of the local repeater frequency showed no activity, so I switched down to the Louisville repeater frequency. The Louisville repeater is about forty miles or more from my home, but there was activity on the channel. I waited and listened for a clear period of time to make a try at keying the repeater. I pushed the mike button and gave my call to see if anything would happen. What a thrill to have a Louisville station come back to me and ask for my location. Since then, I have met many new hams on both the local and the Louisville repeaters. Believe me, this is the mode to use, as there is no noise, lots of consideration and assistance to the newcomer on the band, and many good interference-free QSOs.

After getting used to the Midland, I decided to see what all was in the book and learn a little more about the rig. What a treasure-trove of information I found. Let's see what we have.

First off, the Midland is an all-synthesized unit covering the range of 146.00 to 147.995 MHz. It has a one-Watt low-power position and a 25-Watt high-power position. The modulation is direct F-3 and requires a 600-Ohm microphone, which is furnished. The primary power requirement is 13.8 volts positive dc plus or minus 15%. Duplex shift for plus 600 and minus 600 kHz is furnished. Two provisions are provided for other offset frequencies.

In the receiver, the following information is furnished. It is a double superhet, with a first i-f of 16.9 MHz and a second i-f of 455 kHz. The sensitivity is claimed to be .5 microvolts with 20 dB of quieting at a signal-to-noise ratio of .3 microvolts at 12 dB or more. The audio output is 1.5 Watts into an eight-Ohm load. Frequency control is the popular PLL covering the range of 127.1 to 131.1 MHz with no

doubling in the PLL. There are 39 transistors, 10 FETs, 14 integrated circuits, and 28 diodes in the set. The following accessories are included: mobile mount, dynamic microphone, mike hanger, a spare 7-Amp fuse, external speaker plug, and an accessory plug for the accessory socket on the rear panel. The mount is a snap-in unit, which makes it very easy to remove the rig if you don't want to leave it in the car. The power cable has a three-pin socket that makes for easy removal and is so arranged that only the proper polarity can be obtained when plugging the rig in.

The really amazing thing about the entire unit is the amount of information that is furnished in the operator's manual. Midland really had the do-it-yourself amateur in mind when they printed the manual. The manual includes, in addition to basic hookup and operating instructions, the following: block diagram, schematic diagram, wiring diagram, voltage chart, frequency table with a frequency breakdown diagram, top and bottom chassis photos, detailed printed circuit board diagrams, FET, transistor, and IC terminal guide, coax cable plug assembly diagram, and, the most valuable of all, complete alignment instructions. As you can see, it is one of the most complete manuals that I have seen on amateur equipment in some time.

I do not have the facilities to run any real technical signal-to-noise tests or to check the manufacturer's specifications for what is claimed, but I can tell you that all of the on-the-air checks have been very satisfying. The audio is very clear and plenty adequate for normal use. Very little squelch control rotation is needed to have full quieting. All in all, I would rate the Midland 13-510 as one of the best units on the market for under three hundred dollars. I hope you enjoy your rig as much as I do mine, and maybe someday I will hear you on one of the repeaters across the country. See you on two FM.

Social Events

from page 123

32233. Price at the door will be $3.50.

A large indoor swap area will be featured, with advance table reservations available for $5.00 per table per day from Robbie Roberts KH6FMD/W4, 10557 Atlantic Blvd., #31, Jacksonville, Florida 32211. Information on exhibitors' booths and space are available from the same address.

Other features and programs include statewide organization meetings on such topics as traffic nets and MARS, a microprocessor seminar, a solar power demonstration, a DX "pileup" contest, a hidden transmitter hunt, an OSCAR forum, ARRL forums, emergency preparedness programs, DX and contest presentations, antenna and technical seminars, and much more.

More general information may be obtained from JHA, 911 Rio St. Johns Dr., Jacksonville FL 32211.

LITTLE ROCK AR
AUG 4-5

The Central Arkansas Radio Emergency Net (CAREN) Amateur Radio Club will hold its second annual Ham-a-Rama on Saturday and Sunday, August 4-5, 1979, at the Arkansas State Fairgrounds, Little Rock, Arkansas. There will be two main prizes given, as well as door prizes. Featured will be forums, dealers' exhibits, a Saturday night party, and a large flea market. Talk-in on 146.34/.94. For details, send an SASE to Morris Middleton AD5M, 19 Elmherst Drive, Little Rock AR 72209.

ANGOLA IN
AUG 5

The Steuben County Radio Amateurs will hold their annual F.M. Picnic and Hamfest on Sunday, August 5, 1979, at Crooked Lake, Angola, Indiana. There will be prizes, picnic-style barbecued chicken, Inside tables for exhibitors and vendors, and overnight camping (fee charged by county park). Talk-in on 146.52 and 147.81/.21. Admission is $2.00.

CEDARTOWN GA
AUG 12

The Cedar Valley Amateur Radio Club will hold its annual Cedar Valley Hamfest on August 12, 1979, from 8:00 am to 4:00 pm at the Polk County Fairgrounds, on US 278, two miles east of Cedartown, Georgia. There will be food, drinks, and prizes. Talk-in on 147.72/.12 (WR4AZU). For more information, please contact Jim T. Schliestett W4IMQ, Secretary, Cedar Valley ARC, PO Box 93, Cedartown GA 30125, or phone (404)-748-5968.

LEXINGTON KY
AUG 12

The Bluegrass Amateur Radio Club will hold its annual Central Kentucky Hamfest on August 12, 1979, at the Fasig-Tipton Sales Paddock, Newton Pike, Lexington, Kentucky. The program will include grand prizes, hourly door prizes, manufacturers' exhibits, an indoor/outdoor flea market, guest speakers, and forums. For information, contact the Bluegrass Amateur Radio Club, Inc., PO Box 4411, Lexington KY 40504.

PETOSKEY MI
AUG 18-19

The Straits Area Radio Club will hold its Swap 'n Shop and hamfest on August 18-19, 1979, at Petoskey Middle School, State and Howard Streets, across from the Catholic church and post office, Petoskey, Michigan. There will be a donation of $2.00 at the door. Table space is also $2.00. Refreshments will be available. There will be a swap and shop on Saturday from 9:00 am to 4:00 pm and on Sunday from 9:00 am to 12:00 pm. Prizes, a ladies' program, and seminars at 11:00 am and 2:00 pm on Saturday will be featured. A banquet at the Holiday Inn on Saturday at 7:00 pm will have Mellish Reef DXpeditioner Bob Walsh WA8MOA as guest speaker. Banquet tickets are $7.50 and are limited to 200, sold in advance only. For full Information and lodging, send an SASE to Bill Moss WA8AXF, 715 Harvey Street, Petoskey MI 49770, or phone (616)-347-4734.

ROSEMONT IL
SEP 7-9

The Quarter Century Wireless Association will hold its 1979 Chicago Convention on September 7-9, 1979, at the O'Hare/Kennedy Holiday Inn, Rosemont, Illinois. The complete package for the three days is $35.00. Special room rates will also be available. There will be the annual banquet, special ladies' program, various tours, and prizes. For reservations and information, write Phil Haller W9HPG, 6000 S. Tripp, Chicago IL 60629.

PECATONICA IL
SEP 9

The Rockford Amateur Radio Association will hold its second annual Rockford Hamfest and Illinois State ARRL Convention on Sunday, September 9, 1979, at the exhibition hall at the Winnebago County Fairgrounds at Pecatonica, Illinois, just west of Rockford on US Rte. 20. Tickets are $2.00 in advance or $2.50 at the gate. Tickets are available by mail by writing RARA, PO Box 1744, Rockford, Illinois 61110. Please include an SASE for tickets by mail. Prizes include a Kenwood TS-520S transceiver and an Atlas receiver. Campsites are available on site, with electric and sanitary hookup available. There are 300 flea-market tables available at a nominal charge. Plenty of free parking is available. Featured will be speakers, forums, demonstrations, and discussions. A hamfest menu, including hot dogs, BBQ, and soft drinks will be available at reasonable prices. Talk-in on 146.01/.61 or 146.52.

Corrections

I received some comments on my article, "Build a Hybrid Capacity Meter" (March, 1979, page 40), and would like to respond.

Through my error, I did not catch the missing value of the bypass capacitor on pin 5 of the 555 (IC1). This component is optional, but if it is desired, a value of .01 to .1 uF will do.

I also received a letter concerning inaccuracy on ranges other than the one which is calibrated. I double-checked mine and the accuracy is more than adequate. For those requiring the ultimate in accuracy, the following may be performed: Select a 1%, or smaller, tolerance capacitor that will be a midrange value for the selected range (e.g., ≈50 pF for the 1-to-100-pF range) and adjust the calibration control for exactly 50 pF. The scale will then be as accurate as your capacitor, less any nonlinearity of the meter. Naturally, the range switch should be on the desired range.

I also received a call concerning an inability to get a full-scale reading when testing a capacitor that would normally read at, or near, full scale. This can be caused by several things: leaky rectifier diodes, leaky filter capacitor, meter resistance is too high, or the clock frequency is too low. The clock should be operating between 200 and 300 kHz.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

GETTING THE CROWDS

Dayton knows how to get 'em out by the thousands, but many other hamfests are floundering. Prizes are nice, but how many hams will drive 200 miles to take a slight chance at winning a rig? Not many. If Dayton depended on the prizes to bring in the customers, the mobs would stay home.

The more established hamfests have to keep growing to survive. We've watched the bungling of SAROC into obscurity. It grew smaller and smaller every year, despite lavish prizes. Other hamfests have been withering for the lack of any hot spark to make them grow.

There was a time in history when the ARRL had but to make a hamfest official and this would bring in the hams. Now few hams will drive across town to get to an ARRL forum, much less drive 200 miles. Those who have attended these dreary forums know what I'm talking about. They have been so orchestrated that it is impossible for anything significant to happen. Pompous officials get up and tell everyone how great the League is and how everything is really okay, no matter what anyone else says. End of meeting.

ST. LOUIS

The recent hamfest in St. Louis set an example of what can be done by a live-wire group. Bob Heil K9EID called me up along in December and asked what he would have to do to get me to come out to St. Louis and give a talk to his club in Marissa, Illinois. I said it was simple—just put on a major hamfest and invite me. The next thing I knew he was doing just that.

Bob got all except one club in the area together to sponsor the hamfest, threw in a computerfest to boot, complete with some computer clubs, and ran a bang-up show. Bob contacted the League, but they said he couldn't put on a hamfest without their support, and they had a long list of demands he had to meet to get their support. He decided to go it without them. The result was a superlative success. Over 3,000 hams thronged to the St. Louis Cervantes Exhibition Center, despite lousy weather.

Signing a proclamation for Amateur Radio Day in St. Louis is Mayor Conway. From left to right are Larry Roberts W9MXC, Bob Heil K9EID, Mayor Conway, and beaming me.

What pulled in such a big crowd? It wasn't any ads in *QST*, for there wasn't a hint about the show there. It was mentioned a lot in *73*... about the only place for many hams to get the word. But just reading about a hamfest and actually going are two different things. Something happened to break all those people loose and get them to drive to St. Louis. Despite a competing hamfest in Kansas, a large number of Kansas hams went right by there on their way to the St. Louis show.

I think the difference between the shows is simple to explain. People will go to a show where they think they are going to have a good time. In this case, there was a controversial speaker—me—on tap to talk about things which really can't be published in the magazine. If hamfest committees would spend more time and effort getting speakers who will make hams want to come to the hamfests, they will have plenty of attendance.

The ARRL convention in St. Paul had both me and Harry Dannals on the program. The committee running the convention told me that they doubled the attendance by having me on the program. Sure, I like to hear that... but what this means is that the speaker is of great importance... greater than many

Looking West

Bill Pasternak WA6ITF
24854-C Newhall Ave.
Newhall CA 91321

Attention, nostalgia buffs—have we got something for you! As many of you are aware, K6MYK (now WR6ABN) was one of the nation's first successful amateur repeaters. It has been in almost constant day-to-day operation since the spring of 1956. Anyway, in doing research for a new FM and repeater book, I spent a bit of time with MYK's designer/builder/licensee Art Gentry W6MEP. During the course of one afternoon visit, Art hauled out a true piece of amateur relay history.

In the accompanying photo, Art is busy dusting the cobwebs off the original K6MYK receiver. The receiver was designed and built by Art in the early 1950s and was the first such device specifically designed for mountaintop relay service. It is a single conversion affair with a cavity front end with an overall bandwidth on the order of 40 to 50 kHz. Not exactly narrowband, but in those days it was years ahead of its time. This was an AM receiver, since K6MYK was originally an AM repeater.

This receiver remained in service until about 1969, when it became obvious that FM was going to replace AM as the "in" on two meters. During its lifetime, it performed admirably. Only an occasional tube had to be replaced. This receiver was part of an overall repeater package whose survival and growth pattern helped pave the way for much of what we have today.

AS-RADIO-SHACK-GOES-SO-GOES-THE-???? DEPARTMENT

Of the many magazines, pamphlets, and flyers that come across my desk each month, perhaps my favorite is the monthly flyer published by Radio Shack. No, it's not because of the monthly specials RS runs. No . . . the first thing I do is look for something called the "Flyer Side Chat," written by Radio Shack President Louis Kornfeld.

I've never met the man, but after reading about 35 or so of his columns, I kind of feel that I know him. Through him, I may have gained a bit of insight into the RS operation itself. Tandy/RS is really a company on the grow, and Louis Kornfeld is obviously quite proud of that fact. It's not what he writes, but rather the obvious positive approach with which he writes that makes his pride obvious even to the occasional reader. He is also a very straightforward man who likes to speak his mind; his "Flyer" editorials never beat around the bush.

I mention all this because I have found Radio Shack to be a good indicator of the state of the entire hobby electronics industry. They are trend-setters, unafraid to take a giant step forward if a viable market seems available. Witness the success of their TRS-80 computer and many other RS products too numerous to mention. The nice thing about Louis Kornfeld's "Flyer Side Chat" is that it gives you ongoing insight. To see what I mean, I suggest that you visit your local RS and pick up their current "Flyer." If you are like me, you will probably get hooked on Kornfeld's editorial comment . . . or on a TRS-80 of the kind I am saving my pennies for these days.

THE 220-UP-NORTH DEPARTMENT

Ward Hill WA6FUH is an old friend of mine. I first met Ward in 1972, about a month after moving to the southland. In fact, one of the very first Looking West columns announced his engagement. Since then, Ward and his wife Barbara have relocated in Camino, California, where Ward operates his own dental laboratory. I had not heard from Ward for a long time, until the other day when our "postal lady" delivered a rather interesting note from him that I wish to share with you. It concerns a 220 repeater project that Ward and some other local amateurs are involved in.

It all started about a year ago on 146.52. Ward's house sits at about the 3000' level, and, needless to say, he does not need very much power for good simplex coverage. One day on .52, Ward talked with a group of amateurs in Sacramento who were looking for a location for a 220 repeater. One thing led to another, and when WB6UBF/RPT commenced operation, it did so from Ward's house (where it still resides today). As you may have surmised, UBF has rather good coverage. It is an open machine operating on 223.10 MHz in and 224.70 MHz out, with a 90-degree antenna pattern which gives excellent coverage throughout the Sacramento, Stockton, and Auburn, California areas. It also gives some extended coverage to places as far away as San Jose. Not bad for a home-built system that started life as a Clegg FM-76 transceiver.

By the way, an interesting method was utilized by this group to obtain the desired coverage and pattern direction. Rather than use a J-pole antenna phased for a cardioid pattern, the UBF antenna system consists of four 7-element KLM yagis fed from a four-port KLM power divider (which in turn is connected to a Phelps-Dodge 220-MHz duplexer). They are fanned out at equal intervals to produce the desired pattern. Ward reports that results with this novel approach have been far better than expected.

Currently, UBF has about 15 regular user/supporters, but it also has the welcome mat out for anyone else who wishes to drop by the channel pair. There are plans in the mill for a two-meter remote downlink to selected simplex and repeater channels, along with a second downlink to six meters for operating DX openings and six-meter path experimentation. Other projects on the fire include a complete touchtone decoder system to activate most of the foregoing, along with a secondary power source which might be solar. Of course, all of those plans are dependent upon usership growth and financial support.

Each week, we hear of new 220 relay activity starting up here or there. This is extremely important news, in that it helps ensure the future of that spectrum. It's no secret that our own government is about to try to sell out 220 MHz at WARC '79. We have covered this in depth in recent Looking West columns. What is nice to see is that others agree with my policy of taking the initiative to build 220 activity to a level which would make a 220 maritime takeover a very hard task. Remember, today the old *73* slogan, "220—Use It Or Lose It!", is more important than ever before.

This brings us to a recent special issue of *220 Notes*. Entitled "A Special Action Bulletin," its contents outline what action you and I as individual amateurs can take to try to persuade our government to do an about-face in regard to 220 MHz at WARC. Also included is a suggested form letter to be used as a guide in requesting that action be taken by the FCC to keep 220 to 225 MHz exclusively amateur. The form letter was prepared by Barry D. Bayer K9CFV of the legal firm of D'Ancona, Pflaum, Wyatt, and Riskind. It takes the stand of supporting the Petition for Reconsideration on Docket 20271 filed by the 220 Spectrum Management Association of Southern California. The letter reads as follows:

Secretary,
Federal Communications Commission,
Washington DC 20554

Re: In Support of the Petition of the 220-MHz Spectrum Management Association of Southern California, for Reconsideration of Portion of Report and Order Docket 20271

I am a licensed amateur radio

Art Gentry W6MEP dusts off the original K6MYK receiver.

OMNI HAS IT *ALL*. All the advantages and capabilities, all the new conveniences and new levels of performance you need, whatever your HF operating specialty. All built-in, ready to use.

***ALL* SOLID-STATE.** All the advantages of total solid-state from the pioneer of HF solid-state technology. Reliable, cool, stable — from receiver front-end to transmitter final.

***ALL* HF BANDS.** From 160 through 10 meters (and all the crystals) plus convertible 10 MHz and "AUX" band positions for possible future needs.

***ALL* BROADBAND.** Band changing without tuneup — without danger to the final amp.

***ALL* READOUTS.** Choose OMNI-A for analog dial (1 kHz markings) or OMNI-D for six 0.43" LED digits (100 Hz readability.)

***ALL* VOX AND PTT FACILITIES** built-in; 3 VOX controls plus PTT control at front and rear jacks for external PTT switch.

***ALL* SQUELCH NEEDS** for tuning and monitoring are built-in.

***ALL* FILTERS INCLUDED:** 4-position CW/SSB filter (150 Hz bandwidth with 3 selectable skirt contours) plus 8-pole Crystal filter (2.4 kHz bandwidth, 1.8 shape factor.)

***ALL* MODE SWITCH** puts all filters to work in any mode.

***ALL* BREAK-IN:** Instant or delayed receiver muting to fit any band condition or mobile operation.

***ALL*-VERSATILE OFFSET TUNING;** dual ranges, ±5 kHz range for off-frequency DX or ±0.5 kHz range for fine tuning.

***ALL*-SENSITIVE RECEIVER;** from 2 μV on 160 m to 0.3 μV on 10 m (10 dB S+N/N) for ideal balance between dynamic range and sensitivity.

***ALL* OVERLOADS HANDLED;** dynamic range typically exceeds 90 dB and PIN diode switched 18 dB attenuator also included for extra overload protection.

***ALL* LINEAR/ANTENNA BANDSWITCHING FROM FRONT PANEL;** auxiliary bandswitch terminals on back panel for external relays or circuits are controlled simultaneously by the OMNI bandswitch.

***ALL* INTERFACE JACKS FOR PHONE PATCH;** access to speaker and microphone signals.

***ALL*-LEVEL ADJUSTABLE ALC;** set output from low power to full, retain low distortion at desired drive to power amp.

***ALL* SIDETONE ADJUSTMENTS;** pitch and volume.

***ALL*-POWERFUL, *ALL*-WARRANTED FINAL AMPLIFIER.** 200 watts input to final. Proven design with full warranty for first year and pro-rata warranty for additional 5 years.

***ALL* 100% DUTY CYCLE.** For RTTY, SSTV or sustained hard usage.

***ALL*-MODE POWER:** basic 12 VDC for easy mobile use, external supplies for 117/220 VAC operation.

***ALL* FRONT PANEL MICROPHONE AND PHONE JACKS.** Convenient.

PLUS *ALL* THE OTHER HANDY BUILT-INS: "Timed" 25 kHz crystal calibrator in OMNI-A with automatic 5-10 sec. "on" time for easy 2-hand dial skirt adjustment... Zero-Beat switch for placing your signal exactly on CW listening frequencies... SWR bridge switches "S" meter to read SWR each time you transmit for continuous antenna monitoring... Separate receive antenna capability... Dual speakers for greater sound at lower distortion... Plug-in circuit boards for fast, easy field service.

***ALL*-FUNCTIONAL STYLING.** "Clamshell" aluminum case clad in textured black vinyl with complementary nonreflective warm dark metal front panel and extruded aluminum bezel and bail. Convenient controls. Complete shielding. And easier-to-use size: 5¾"h x 14¼"w x 14"d.

AND *ALL* THE OPTIONS: Model 645 Keyer, Model 243 Remote VFO, Model 248 Noise Blanker, Model 252MO AC Power Supply.

Model 545 OMNI-A $899   Model 546 OMNI-D $1069

Experience the *all*-encompassing HF world of OMNI. See your TEN-TEC dealer or write for *all* the details.

LETTERS

FREE SPEECH

Recently, the world has witnessed the worst nuclear accident in the history of the United States. On the east coast, and especially in central New Jersey, this incident has made residents aware of how vulnerable we are to next-door nuclear technology.

Amateur radio is now, as it has always been, a prime vehicle for the exchange of ideas and for open discussions between and among concerned licensed operators. For example: Senator Goldwater K7UGA converses with social studies students throughout the country, Columbia University W2AEE initiated the National Student Information Net (40m) during the 60s, and so on.

Since then, however, something has been added to amateur radio. State-of-the-art technology (but not state-of-the-art thinking) has produced the repeater—that wonderfully-efficient contraption capable of fostering human interaction and "communications."

Amateurs throughout the country in the style of "New Directions Radio" are discussing the issues, learning from each other, and forming views which may, in the future, preserve not only amateur radio, but a large proportion of the population as well.

Repeaters with their associated control operators, in many cases, *prevent* communication from taking place. Witness: a discussion of events on the 147.645/147.045 Asbury Park repeater between Bob WA2DEX and myself, WB2MIC. The topic of discussion was the events which took place the previous day in Lacey Township during a scheduled debate between the Jersey Central Power and Light Company and the Safe Energy Alternative Alliance. One individual of the SEA Alliance was arrested while questioning a plainclothes police officer who was recording license plate numbers. The legality and purpose of this officer's actions were described and discussed. Bob is familiar with such matters.

At this point, some true American (protector of free speech and Mom's apple pie) touchtoned the repeater off the air without identifying the transmission—breaking the law, in fact! Whether in self-preservation or as an expression of neo-fascism, this individual deliberately violated an FCC ruling, and did not possess the courage, decency, or intellectual fortitude to explain or admit his actions. The only alternative was to complete the QSO on the repeater's reverse-frequency pair.

There is no argument or debate over the right of a control operator to shut down a repeater. The concern is that such an important issue as nuclear power now has individuals who consider it a controversial topic—one that is taboo.

Let free speech prevail! Let the basic tenets of this nation stand, not only throughout the country but throughout amateur radio as well. After all, ham radio is part and parcel of our entire framework of freedom. Let the open forums happen.

Finally, it is easy to identify the ham neo-Nazis and all they represent by simply engaging in a friendly open dialogue with smatterings of relevance. They'll run and hide, only to plot behind the curtain of the executive committee meetings. There they feel important, in a world and modified hobby that is so far intellectually removed and unaware that the only consolation is peer friendship and closeness. Watch them; observe them; identify them; but most of all, feel sorry for them. But make certain that your views and your right to search for a meaningful QSO are not repressed!

Jozef Boniakowski WB2MIC
Neptune NJ

THE IARL AND TAPES

Regarding your conception of the IARL, please go for it, as you have my support. I am so tired of hearing the League "line" at the hamfests and in their magazine. It seems ludicrous to think that people who can sink as much money as they do into their hobby can't afford another $10, or more, a year to protect their interests, and regardless of League claims, lobbying is the *only* way to do that. Perhaps you're correct about the contests being the way to establish visibility. But, as an avid contester, I feel there are enough contests now, and setting up more may cause us to lose support from those who really dislike contests. It may also tend to cloud the main purpose of the organization. In any event, I hope you'll be ready to go when the time becomes right.

Perhaps you're tired of hearing success stories about your code tapes, but I'm going to relate one, anyway. Two friends of mine, one a Technician and one with an Advanced ticket, were preparing for FCC tests at a local hamfest. I gave the 20-wpm tape to my friend with the Advanced, and subsequent QSO-type tests that I sent him on the air confirmed that he would have no trouble with the test. My Tech friend has been away from code for so long that it looked like a real challenge.

I started him off with your beginner's tape and then gave him the 13-wpm tape. His progress seemed somewhat slow, and he further seemed to have difficulty when I sent him QSO-type tests because he would tend to read the copy and get lost. So I set my sending/spacing to match your 13-wpm tape and made up several QSO-type tests with questions for him, so he would have a better idea of what to expect at the actual test. At the hamfest, I learned early that my Advanced friend had passed his code test; I waited like an expectant father to see if my Tech friend had passed his 13-wpm test. He finally emerged all smiles, as he had passed the test—at 20 wpm!

While I don't recommend using the 13-wpm tapes to prepare for the Extra, this should give you an idea of the margin of safety in the tapes.

R. Michael Reed K0UP
Wolbach NE

SLAMMING

I got to the point when I had to write. I got my Novice ticket in December of 1976, my General in October of 1977, and my Advanced in June of 1978. I have had a subscription to *73* and *QST* since that time and think they are both very good magazines. I just got tired of you putting down the ARRL. Anybody who does something will make mistakes; maybe that's why you don't.

I have yet to see any other magazine cut the others down like you do *QST*. You just can't seem to resist a chance to put the slam on them. I don't know what your personal grudge is against them, but I do think it's about time you started using your editorial for other things besides devoting 75% of it to knocking the ARRL.

I have never been able to find W2NSD/1 giving code practice on the air. As far as the 50-year-old code tapes by the ARRL are concerned, I learned the code in one week from it. You say you dislike putting in the commercial for *73* tapes, but you still put it in, didn't you? I am going to get the *73* 20-wpm tape and, if it's as good as you say, I should be able to pass the Extra code test after the first time through, since it took a week with that no-good ARRL 50-year-old tape.

In your January issue, you say *Radio* magazine had better projects by far than *QST*. Why? Because you don't like *QST*?

I made a few projects out of *QST* and they worked right the first time. So far, I haven't found anything in *73* I wanted to make. So does that make *QST* by far the better magazine?

Wayne, I think it's time you started working with/for amateur radio instead of against *QST* all the time. You can start by stating in your editorial what you and *73* are doing for amateur radio, just to refresh our memories.

I don't really expect to see this printed in *73*, but I just thought I would let you know my feelings. If I were knocking *QST*, I'm sure it would get in print.

Best regards to you and yours, Wayne; 73s for now.

Milford MI

TRAM DIAMOND 60

I have been keeping fairly close tabs on your articles on CB-to-10 conversions, but I must have missed one, because I haven't seen anything on the 23-channel Tram Diamond 60 SSB rig. You have a great mag. Keep it up.

Larry Seymour WB9UFT
Mahomet IL

Hang in there, Larry. Your rig will be coming up.—Jeff DeTray WB8BTH, Assistant Publisher.

OVERVOLTAGE

Although few hams build their own transmitters and receivers as in the days of AM, there is much home brewing in the area of station accessories—keyers, computers, test equipment, etc. Power supplies are popular to build so that the 2-meter rig can be used at home as well as in the car. Power supply circuits are so common and many hams have a false sense of security, particularly with the "new" 3-terminal regulators with thermal shutdown, current limiting, etc.

Unfortunately, overvoltage protection is almost universally avoided. For an adjustable regulator, it is *complex*, but for a fixed voltage or limited range supply, it is quite simple.

Check the reference books. An SCR, resistor, and zener are about all you need, and prepackaged circuits are available commercially and surplus. A dollar or two is pretty cheap insurance when you consider how a blown regulator could do many dollars of damage to that 2-meter rig, computer, or whatever.

Personally, deleting overvoltage protection for solid-state circuits is a crime which I hope never to commit. But check the articles; there are a lot of power supply circuits waiting to prove the point.

E. P. Rolek K9SQG/8
Dayton OH

COME ON UP

Come on up—the air is nice and clean. Don't let all the articles published about 220 MHz scare you. My friends and I here on Long Island have enjoyed this band for quite awhile; we need support now. So, if you have a 220 rig, please use it.

Ed Beinlich WB2IBQ
Whitestone NY

INFLATION

Don't let this inflate your ego, but it must be said that your magazine gets better with each issue.

I got quite a kick out of the recent letter you printed from (my friend) Merrill Eidson of Temple TX. (He's one of my crystal suppliers for those ¼-inch thick AT-cut blanks and crystals for radiobeacon equipment at Alaskan airports. He's the *last one* on the continent who makes up these very important crystal units in the old FT-164 3-inch round white ceramic holders with two nickeled studs protruding.) But I agree with you as being right on in criticizing the ARRL.

F. W. Anderson W7AR
Seattle WA

MORE ON TAPES

Around the middle of January, I received your 20- and 25-wpm code tapes. At the time I received them, you expressed an interest in the amount of time I spent going from the General class speed to the Extra class speed.

The total time I spent was seventy-one hours. I am able to copy the 25-wpm tape now with an error rate of about 3%. The difficulty of the groupings and the added 5-wpm speed was just what I needed to push me into the 20-wpm plain text required by the FCC.

Without the skill I acquired from the tapes, I'm sure I could not have passed the code test. I think they are excellent, and I would certainly recommend them to anyone wishing to upgrade.

Larry L. Sias N0ASV
Kansas City MO

BACKSTABBING

Recently, a friend loaned me an October, 1978, copy of *73* (the first that I have read in years) to review info contained in the article, "Mighty Mods for the 820S." I was very interested in your editorial on "a woman ARRL director." I have been following *the action on* Mary Lewis vs. the ARRL, Thurston, et al, and, while not having all the details, I always felt there was backstabbing, etc. As you probably know, HQ has received two petitions from Northwestern Division members. One requests that ballots be released for election of Director, and the other asks that Vice Director Mayer K7BT be appointed interim Director until the election takes place. You will note from minutes of the January 24-25, 1979, Board of Directors meeting (March, 1979, *QST*), Vice Director Mayer apparently was not allowed by Thurston to attend (out of Division funds), although 10 other Division Vice Directors did! With regard to the last paragraph of that portion of your editorial, I absolutely agree.

Walter R. Joos W6EKM
Vacaville CA

BIG PROJECT

With your reputation for advancing the amateur radio field, I would like to suggest a booklet that would be of great use to the beginner in this field. Namely, an evaluation of amateur equipment for the past fifteen or twenty years, which would include the good and bad points of each, the original cost, possible current value, and some judgment of the equipment.

If you and your associates could work this out, it could be of value for the beginner in buying his first or successive sets.

Don Hurley VE3HAN
Brighton, Ontario

That's an awfully big project, Don. Does anyone want to take on this project?—Jeff DeTray WB8BTH, Assistant Publisher.

GALLED

I am a new Novice. I have bought $50 worth of books which I study at least 8 hours a week. I subscribe to both *73* and *QST*. I *am* going to get that General. I am building a 40-meter QRP rig designed by a local ham, but I do have a problem which you seem to be unaware of.

73, *QST*, and all the manufacturers do not realize that the typical new Novice has limitations as to what he can do. I would like very much to build the Mini-Miser receiver in the *Handbook*. The assembly of parts on boards offers no problem, but I cannot manufacture PC boards, the shielding, and the cabinet. Therefore, it won't be built and we both lose.

Another thing that galls me is the way your publication lacks simple and thorough articles for the Novice. Maybe when I get my General, I will be equally arrogant. I hope not.

Nate Bushnell KA0DGN
Littleton CO

SMALL PROBLEM

I read your March, 1979, article on the universal alarm circuit. It came out just at the right time. With high water levels during the spring thaw, water seepage into the basement started to become a problem. If I had this early warning system built, I could rectify the situation before it caused any damage.

I went down to the local parts emporium and picked up a HEP C4001P McMOS chip. It states on the package: "Pin-for-pin replacement for CD4001A," which is what the project called for. There was only one thing overlooked and that is the type of gate HEP thinks a CD4001A is. Their chip is a quad 2-input NAND gate which, of course, is not correct for the alarm. If you have to use the HEP line, get their C4000P which is a quad 2-input NOR gate, even though HEP thinks that it is a "pin-for-pin replacement for a CD4000A."

Now that this small problem is out of the way, the alarm is complete and works great.

Dave Faucher WA1UQC
Collinsville CT

THANKS

Recently, I was successful in obtaining my Extra class license. Many thanks are due to the editors of *73 Magazine* who put together that TAB book, *Amateur Radio Extra-Class License Study Guide*, which I used as the basis for my self-conducted study program in amateur radio theory and practice over the past several years.

I found the topics introduced there to be an excellent starting point for study of the extensive literature surrounding amateur radio. I undertook this as a surprisingly-enjoyable pastime whenever I found the time to continue with it. As a result, I have been able to reach the point where I am confident that I can be of considerable assistance to the ham fraternity and the public which we serve.

Thanks are also in order for the *73 Magazine* code tapes which I found helpful in brushing up on the 20-wpm code speed needed for the Extra class license exam.

Thomas C. Kipps KA6Z
Fresno CA

QRP ZONE

We're in the process of taking the advice of K5UKH (CB to 10—part XV, November, 1978) and converting a currently-discounted ($34.88 each) Realistic walkie-talkie, Model TRC-201, to ten meters. This unit is identical to the TRC-180 which Tom Murphy K5UKH modified. The receiver in this unit is unusually hot.

International Crystal has the correlation for providing us the pair for 29.000 MHz. Another unit, the 5-Watt TRC-208 with 6 channels, is tempting as it would provide a tight band of 6 channels from 29.000 through 29.050 MHz for QRP operation. A 12-volt power cord plugged into the car lighter liberates you from dying carbon batteries or flagging nicads.

This is the time, Wayne, to stimulate hams into honoring and using a QRP zone, because there are already such large areas on ten for other modes of transmission other than AM.

I would welcome correspondence from interested hams. Service bulletins ($2 each) are available through Radio Shack stores.

PREPARING YOUR PROGRAMS

One of the problems facing many microcomputer users is the preparation of software for their particular applications. The software examples which we have provided in past columns are short enough to have been put together or *assembled* by hand, i.e., we translated each mnemonic into its octal, hexadecimal, or binary equivalent. Addresses for jumps, calls, and input/output devices are easily added or changed since the computer programs are short and the addresses are probably listed in sequential order on the rough draft. Unfortunately, not all software preparation is this easy. Many application programs can be many thousands of steps long. This column will initiate a discussion of the aids available for microcomputer program development.

One of the biggest problems in software development is the clear, concise statement of the problem and how it is to be solved. All of the desired results, inputs, outputs, and the complete program flow, including all decision-making steps, must be considered before the programming is started. This can be in outline or block diagram form, but a flowchart will prove to be much easier to follow. A typical flowchart is shown in Fig. 1.

After the problem has been well thought out and a solution put in flowchart form, a decision must be made. Is the program short enough to be easily translated by hand? In many cases, particularly where the programs are simple, hand assembly makes sense. In other cases, software development aids called *editors* and *assemblers* are faster and more efficient. To understand how editors and assemblers work, let's consider the process used to put together this column.

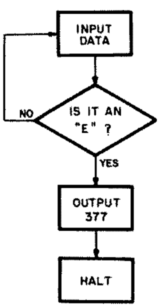

Fig. 1. Typical flowchart.

The first step is an outline of the subject so that we can cover it well in the short column format. A handwritten copy is then typed, corrected, retyped, and perhaps corrected and typed a final time. The illustrations and examples are formulated and drawn separately. This is the *editing* process. When writing a column, it is best to avoid references such as, "the example below" or "the table on the following page." When the column is composed or *assembled*, references to Table 1 or Fig. 4 are much easier to follow.

Computer software is developed in much the same way. An editor program is used, either on a microcomputer or a time-sharing system, to edit the individual program steps. The editor program can correct program steps, change steps, and insert and delete steps just as an actual editor can do with a manuscript. The editor program is generally unaware that you are writing a computer program, since you can use most editors to write a letter, prepare mailing lists, etc. When using an editor to prepare a program in mnemonic form, *symbolic addresses* are often assigned to software tasks within the program. In this way, the actual value of the addresses for subprograms or subroutines is not needed. Just as we can refer you to Fig. 4, the program may similarly refer to the letters, LOOP, as the starting address of a time-delay loop. Allowing us to use symbolic addresses for program steps means that the program may be changed without regard to the actual numeric values of addresses.

The assembler program must be such that it accepts information from the editor and generates an output in a form compatible with your computer. Just as you assemble short programs a step at a time, so does the assembler. The assembler contains a table of mnemonics and their equivalent values. For example, an 8080 assembler would translate an MVIA instruction into 076 octal. The assembler also assigns real 16-bit addresses to your symbolic addresses, such as LOOP. When using symbolic addresses, you must be sure to have a program step for each symbolic address, and you must assign an address if you use a symbol. You cannot assign the same "name" to more than one address. Most assemblers will recognize a *redefined symbol* or an *undefined symbol* and will produce an error message to let you know what needs to be corrected.

The final assembler output will be in punched paper tape, cassette, or disk form ready to run on your system. Most assemblers will also produce a listing of the program showing the address of each step, the data in each successive location, a symbolic address name, and the mnemonic, plus any comments. A typical assembler output is shown in Table 1.

After a program has been assembled, it will probably have to be debugged to get it to operate properly. The program checkout and debugging can be painful without additional software "tools." Computer control panels often prove useful, but reading binary codes can become tedious, and there are many computers without external controls and readouts. As an alternative, there are *debugging programs* available for most microcomputers which allow you to charge instructions, list blocks of data or instructions, and single-step through a program one instruction at a time.

One feature of many debug programs is the ability to establish a *breakpoint* in the software being tested. When the computer reaches a breakpoint, the instruction at that address is executed and an output device, such as a teletypewriter, lists the contents of important, internal CPU registers. Breakpoints are very useful since they indicate not only that the computer reached a certain point in the software, but also what the computer was doing when it got there. If a breakpoint is set in the normal program flow and is not reached, there is something wrong with the program. In this case, the breakpoint would be moved closer and closer to the start of the program until the error is found. When the error is found, it may be corrected by using the debug program to change an instruction, data, etc.

Once the program is operating correctly, the debug program should have the means of saving it on paper tape, a cassette, or another medium. It should also be able to read such

Continued on page 154

GLOSSARY

Editor:	A program that allows edit functions such as addition of a line or character to a program, insertion, deletion, etc. It permits you to alter your program. The input data could be anything from programs or reports to raw instrument data.
Assembler:	The program that converts the assembly language code into machine code, accepting mnemonics and symbolic addresses instead of actual binary values for addresses, instructions, and data.
Monitor:	A program which controls the operation of the various programs available. The monitor will be able to access the editor, assembler, or other programs.
Debugger:	A program which allows the user to observe the program flow and the results of the program's operation in a step-by-step mode. A debugger may be used to change data or instructions, alter registers, etc.
Breakpoint:	A special instruction which may be inserted in a program to break off the normal program control and return control to a debug-type program. When a breakpoint is executed, the debug program will indicate what the computer was doing at that point.
Cross-Assembler:	An assembler program which will generate the binary code of a program for a computer other than the type it is being used with. For example, an 8080 cross-assembler might operate on a PDP-8 minicomputer.

Contests

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

MINNESOTA QSO PARTY
Starts: 1800 GMT June 2
Ends: 2359 GMT June 3

This year's contest is sponsored by the Heartland Amateur Radio Club. There are no mode or time restrictions, but only one transmitter is allowed in operation at any one time; no crossband contacts are allowed. Novices compete with other Novices, Technicians with other Technicians. Novices and Technicians must identify their license class when sending their call as "/N" or "/T". Phone and CW are considered to be the same contest; please score as such. Net QSOs are not valid.

EXCHANGE:
RS(T) and MN county or ARRL section/country.

SCORING:
MN stations multiply total of points by the number of sections plus DX countries (W/VE excluded). Others multiply QSO points by the number of MN counties worked (87 maximum). Score one point per phone QSO and 2 points per CW QSO. Novices/Technicians count 5 points per QSO. Contacts with HARC station WBØTTZ count 10 points per QSO on each band.

SUGGESTED FREQUENCIES:
CW—28150, 28050, 21050, 21150, 14075, 7075, 7125, 3725, 3600.
Phone—28700, 21400, 14300, 7275, 3950. WBØTTZ will also be operating RTTY on each band.

ENTRIES & AWARDS:
Include a check sheet for each band/mode used if you make 50 or more contacts. Logs must include date/time (GMT), bands, modes, and exchanges. Usual disqualification criteria and classes of awards, plus county awards to MN stations with 10 or more QSOs. Logs must be postmarked no later than July 1st; include an SASE for return of awards and contest summary. Send to HARC, c/o Scott Nelson WDØEFZ, 421 W. Wisconsin Ave., Staples MN 56479.

SOWP 4th ANNUAL CW QSO PARTY

The SOWP 4th Annual CW QSO Party is sponsored by the Society of Wireless Pioneers (SOWP) and will be held from 0000Z on June 6 through 2359Z on June 7. There are no formal requirements except an exchange of name, membership number, and QTH. Suggested frequencies are 55 kHz (±5 kHz) up from the low end of each amateur band. Novices will operate in the center of each Novice band. Members who can only participate part-time are requested to make their calls on the even hours during the period. To optimize long-distance contacts, it is suggested that ten and fifteen meters be used from 1400 to 2100 hours Z. The call will be CQ SOWP. A special certificate will be available to all members who contact a minimum of ten other members during the period. Requests for the certificate must include a list of stations contacted, dates, times, and membership numbers. In addition, an SASE must be included. Certificates will be issued by the V.P. for Awards, Manuel "Pete" Fernandez W4SM, 129 Hialeah Road, Greenville, South Carolina 29607. Requests must be submitted not later than 30 June 1979.

DAFG SHORT CONTESTS FOR 1979
SW (80 and 40 meters):
Saturday, June 9, 1300 to 1800 GMT
Sunday, September 9, 0800 to 1100 GMT
Saturday, November 24, 1300 to 1800 GMT
VHF (2m and 70cm):
Sunday, June 10, 0700 to 1100 GMT
Saturday, September 8, 1200 to 1600 GMT
Sunday, November 25, 0700 to 1100 GMT

The DAFG sponsors this year's short contests and welcomes participation of all RTTY amateurs both inside and outside of Germany. There will be an SW and a VHF contest, both contests being scored separately. The contest is split into 5 single contests within the year. After closing the 5th single contest, the winner of the year in each classification will be announced. Note: The official rules were received too late to list the dates for the first two weekends in January and March.

General call is "CQ DAFG CONTEST." On SW (80 and 40 meters) after each QSO, the station having called last keeps the frequency. The previous holder should QSY. This rule is not valid for the VHF part! Each station may be worked once per band. Contacts via repeaters are not valid. Classifications include: SW—Class A: SW stations above 200 Watts input; Class B: SW stations up to 200 Watts input; Class C: SWL stations. VHF—Class D: VHF stations.

EXCHANGE:
RST, QSO number starting with 001, name, and QTH.

SCORING:
SW—Each completed QSO counts 1 point on 80 and 40 meters.

VHF—Each completed QSO counts 1 point per each 10 km distance on 2 meters and 3 points per 10 km on 70 cm. Each different prefix per each band will be counted as a multiplier. Final score is QSO points multiplied by the total of multipliers.

ENTRIES:
Logs must contain call, name, and complete address of participant in block letters, classification, time (GMT), call, QTH of partner station, RST and QSO number sent/received, band used, and number of prefixes worked. Show final score; logs without final score will count as checklogs. For SWLs, scoring is the same as above; the same station may be reported a maximum of 5 times. Instead of message received info, the SWL should report call of partner station (worked). The results will be published in the news bulletins of the DAFG, in *RTTY Magazine*, in the DARC magazine, and in foreign courtesy publications. Your log should be in the hands of the contest manager not later than 20 days after closing each single contest. Each later incoming log will count as a checklog only. All decisions are final. Send entries to: Klaus K. Zielski DF7FB, PO Box 1147, D-6455 Erlensee 1, West Germany.

All non-DL participants will receive the results of each part of the contest by regular mail. An award will be given every participant at the end of the year. Special plaque for the top scorers in each classification stated in the annual results.

ALL ASIAN DX CONTEST
Phone: 1000 GMT June 16 to 1800 GMT June 17
CW: 1000 GMT August 25 to 1800 GMT August 26

The purpose of this contest sponsored by the JARL is to increase the activity of radio amateurs in Asia and to establish as many contacts as possible during the contest periods between Asian and non-Asian stations. All amateur bands below 30 MHz may be used. Entry classifications include: single operator, 1.9 MHz band, CW only; single operator, 3.5 MHz band; single operator, 7 MHz band; single operator, 14 MHz band; single operator, 21 MHz band; single operator, 28 MHz band; single operator, multiband; multi-operator, multiband.

Power, types of emission, and frequencies used must be within the limits of your own station license. General call for Asian stations is "CQ TEST," non-Asians use "CQ ASIA." No crossband contacts are allowed. For participants in single-operator classes, never transmit two signals or more at the same time. For multi-operator participants, never transmit two or more signals on each

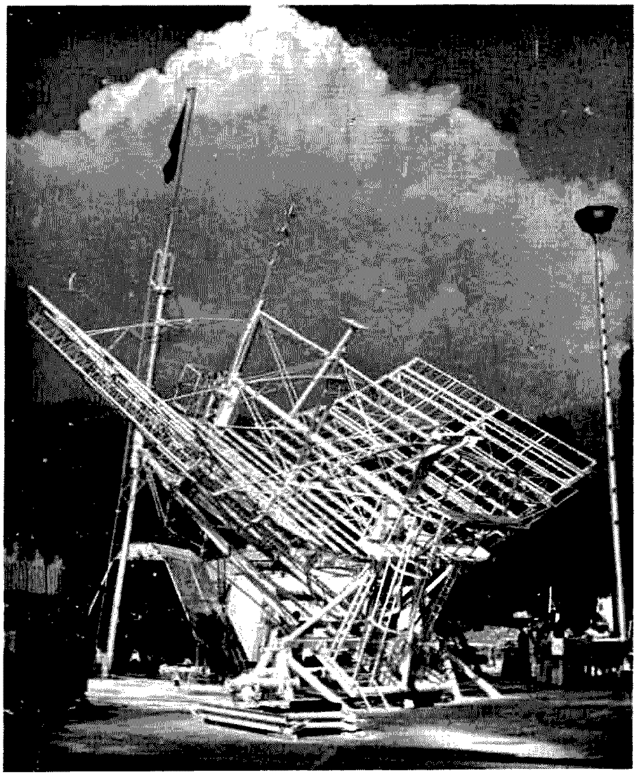
Faces, Places

The Heart of America Radio Club WØRR (Kansas City MO) provided communications at the 1979 Leukemia Telethon. Among the 35 ham participants were Camille Norton WBØYBA, John Bauerly WBØNKR, and Stephen Lufcy WBØLFY.

Last November, LIMARC (Long Island Mobile Amateur Radio Club) members erected three new ATV repeater antennas at their new Syosset, New York, site. The installation crew included (left to right) WB2KCD, WN2VVR, W2MVS, W2KPQ, KA2CLQ, W2TRP, WA2SHC, WB2WAK, N2FP, K2LIO, and WB2SDG. (Photo by K2JKX)



George Romanisky WA6WXD, Los Angeles County Sheriff, was on duty at the Pasadena Rose Parade on New Year's Day. At the time the picture shown was being televised on national TV, he was in QSO through the WR6ABW repeater landline linkup with repeaters WR7AKI, WR8ACC, and WR4ABR.

A few of the hams who pulled emergency duty at the Grumman Corporation's amateur radio station during the Iranian crisis were (front row, left to right) Dick Townes, Skip Courtney; (back row) Zac Zilavy, Ray Schubnel, Jim Kearney, and Jack Cottrell. (Photo by Rich Breunig)

(Left) This solar thermal steam electric generator array is under construction at the Jet Propulsion Laboratory's Pasadena, California, parking lot. A dedicated group of young people has been donating its efforts over the past eight years to build this device for the people of Pitcairn Island. When completed, the array will deliver 5-8 kW in good sun, hopefully allowing the islanders to stretch their increasingly costly supply of diesel fuel a little further. (Above) At the JPL club station W6VIO, Dick Piety K6SVP (left) made contact with Tom Christian VR2TC on Pitcairn. Present in the shack at the time was a group concerned with how to get a very large and heavy structure from the sea in Bounty Bay up a sheer cliff on Pitcairn onto the surface of the island. The group included the New Zealand Consul General for Los Angeles, Frank Muller (right). The consensus was that only a Chinook-type military helicopter would be able to accomplish the task. Any offers? (Photos by Dr. Norman L. Chaflin K6PGX)

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

This month we begin the third year of RTTY Loop. What better way to celebrate a birthday than to investigate once more the hottest topic around today: microprocessors in RTTY. A year ago we looked at reception techniques; this month and next will cover transmitting.

While RTTY transmission can quickly get complicated with various buffers and special function generators, our first efforts shall be directed at merely producing a program that takes keyboard input and converts it to standard RTTY output. We will hold other considerations for later and deal here with the code conversion, speed conversion, and interfacing.

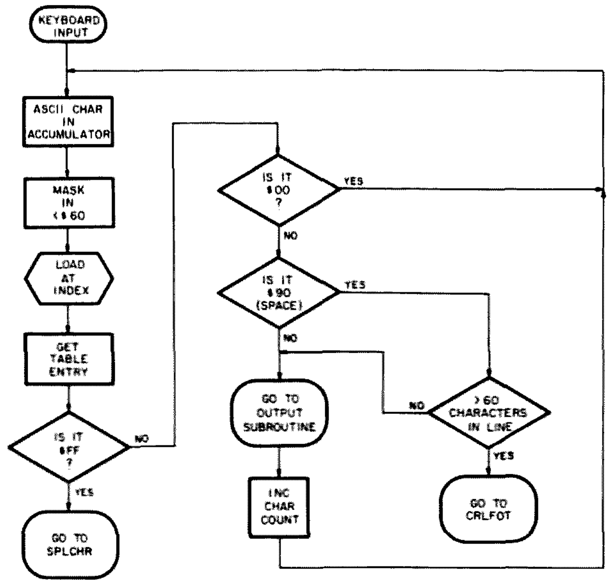


Fig. 1. Main program loop.

Much as we did for RTTY reception, let's enumerate our goals in RTTY transmission: (1) input a character in ASCII from the keyboard; (2) convert that character to the Baudot equivalent; (3) maintain LTRS-FIGS shift appropriately; (4) put the character out at 45.45 baud (60 wpm).

There are also a few niceties we may like, such as downshift-on-space or automatic carriage return/line feed. We will try to incorporate these as the need appears.

The first step, inputting the character as ASCII from the keyboard, is straightforward. Essentially, all computers have an inputting routine, such as the MIKBUG™ INEEE routine, to accomplish this. The only requirement is that the routine mask off the MSB of the input. The ASCII that we use is a seven-bit code, and the eighth bit will confuse things.

Before we get too deeply into this in words, let's walk through the first flowchart, shown in Fig. 1. The keyboard input places an ASCII character into the accumulator. Values greater than $5F are tested for. These represent lowercase and, if present, would cause the table read to search out of the table. If the ASCII code is greater than $5F, it is converted to its uppercase equivalent by subtracting $20. This value is then used as an offset for an indexed search which loads the corresponding table value back into the accumulator. This Baudot-keyed value is either $00, $FF, $FE, or a representation of the Baudot character. If the latter, the format is as shown in Fig. 2.

While the conversion from ASCII to Baudot may at first glance seem to be rather formidable, it really involves the same kind of look-up table as the Baudot-to-ASCII transformation in the receiving program did. By encoding several loca-

DX

Chuck Stuart N5KC
5115 Menefee Drive
Dallas TX 75227

Summer is here—the summer of the greatest DX conditions since 1957. Those of you who have been around long enough to have seen a complete sunspot cycle know that it has not always been like this nor will it be like this forever. Perpetual sunspots exist only in DX Heaven. To you newcomers, we can only advise that you take advantage of your good timing and work everything possible while you can. In years hence at future club meetings, the newer generations will hasten to gather at your feet and listen to unbelievable stories of cycle 21.

DX PROFILE

This month we profile not a who but a what, the Northern California DX Foundation. If you are not a member, you are missing out. Drop a note to Box 717, Oakland CA 94604, for complete information on how you can become one of the deserving ones.

The NCDXF was started in 1972 by K6KQN. Its purpose . . . to assist radio and scientific events with funds or equipment. It would be supported by donations from those who benefit. It would provide a central point where funds could be collected and dispersed . . . after applications for assistance were carefully screened by the Board of Trustees.

The Board of Trustees would be a panel of responsible persons, prominent in the electronics industry or business world, having amateur radio (especially DX) for a hobby. They would give their services and counsel to the NCDXF at no salary or compensation in any form. That was the goal.

If you have worked everything, then all the Foundation can offer is the satisfaction of helping others. If the hobby has given you pleasure, put something back to help someone else. The list below has received aid from the NCDXF and must have given some of you a new country. Were any of them new for you?

1974: ARRL Foundation, VR3AG = Fanning, KP6KR = Kingman, OH2BH/OJØ = Market, XU1AA = Khmer, KP6PA = Palmyra, W6WX/KJ6 = Johnston, and OSCAR/AMSAT Project.

1975: CR9AK = Macao, 3B8DA = Mauritius, JY8BH = Jordan, CT9AT = Madeira, C5AZ = Gambia, KC4NI = Navassa, OHØAM and OHØDX = Aland, SV1GA = Mt. Athos, HBØBZD = Liechtenstein.

1976: A35NN = Tonga, 9N1MM/7 = Nepal, ST2SA = Sudan, ST2SA/STØ = So. Sudan, ZK2AQ = Niue, HKØAA = Serrana Bank, TA7ABK = Turkey, YMØAA = Geyser, VK9XX = Christmas Island, HKØAA = Bajo Nuevo, Moonbounce Expeditions—HK1TL = Colombia, So. America, K6YNB/KL7 = Alaska, N6NB = VHF states VT, RI, DE, WV, UT, NV. And we provided an SWL receiver to a boy with a terminal illness.

1977: KP6BD = Kingman, The Personal Foundation, 3B8DT = Mauritius, SU1IM = Egypt, KP6AL = Palmyra, VP8ON = Falklands, 4U1UN = United Nations Amateur Radio Station.

1978: PYØRO = St. Peter/Paul, ZL1BKL/K = Kermadec, K5YY/FH8 = Mayotte, D68AF = Comoros, FH8CY = Mayotte, YI1BGD = Iraq, ZS3 = Walvis Bay, VK9YS = Cocos-Keeling, STØYY = So. Sudan, WØRJU/KP1 = Navassa, K5YY/ST2 = Sudan, FOØXA = Clipperton, CEØAE = Easter Island, LA1VC = Bouvet, ARRL IARU "Project Goodwill."

Application for assistance must come from the person or group directly involved. It takes too much time to deal with 2nd and 3rd party requests. And they must be processed through PO Box 717, Oakland CA 94604, not via a trustee.

Application processing time: The NCDXF has nine trustees that must vote on the requests. They seldom have meetings, so voting is done by telephone. Don K6RV, the president, calls each trustee long-distance (at his own personal expense) to poll the votes on various items. Allow plenty of time for processing.

Equipment donations are encouraged, but must be trouble-free. It is asking too much to expect the Foundation to find a repairman. You are the one that gets the tax receipt.

Membership: Anyone is invited to become a member. A minimum donation of $5 is required to cover membership certificate, etc. There are no yearly dues or demands, but the Foundation must have an influx of capital if it is to continue, so they encourage a yearly contribution. For USA tax purposes, they are classed as a private operating foundation, defined in Code Sect. 4942(1)(3), which allows up to 50% of your adjusted gross income to become a deductible contribution. If you are in a position to make a substantial donation, write for details.

Last month we showed you the SSB operating position at KV4AA. Above is the CW position from where most of the almost unbelievable 48,100 QSOs were made during 1978.

HEARD ON THE BAND

The Desecheo operation, KP4AM/D, was a roaring success with over 21,000 contacts made on all bands 2 through 160. The QSLs were expected to hit the mails in early May, so you should have yours in hand by this time. Although the operation received financial support from the Northern California DX Foundation, it is still several thousand dollars in the red. Those wishing to help out can direct their mail to the DX Club of Puerto Rico, PO Box 50073, Levittown PR 00950. Those taking part in the operation were KP4AM, KP4Q, N4EA, KP4DSD, KV4KV, and N4ZC.

EA6CE was a multi-operator effort in the recent ARRL DX Contest. They managed some 3,000 contacts in a forty-eight hour period and ended with better than 1.5 million points. QSLs should be directed to PO Box 31, Palma de Mallorca, Balearic Islands, Spain.

While we are reporting from Spain, we might mention that Fernando EA8CR sends word that permission has been granted for 160 activity from Spain. This includes the EA6/8/9 types as well, and, while there may be some restrictions in some areas, you should soon be hearing all the EAs on 160.

George Collins VE3FXT was mobiling around the US last summer and dropped in on the Fresno International DX meeting. George is planning quite a bit of DX activity in the coming years, including a massive effort preceding the 1984 Olympics. Plans call for a complete mobile station possibly set up in a light aircraft to move quickly from place to place. His itinerary of well over 100 countries will warm the hearts of many DXers. George has some 11,000 contacts from H5 and S8 and he reports that the gear for Vendaland is already in place.

Speaking of those new African homeland countries, you should be hearing Vendaland and Qwa-Qwa before the year is out. These two, along with H5, Bophuthatswana, and S8, Transkei, should be added to the ARRL DXCC countries list as soon as WARC 79 is history. They most certainly will be made retroactive to their independence dates, so go ahead and work them even though they won't count for a while. There is also the possibility that South Bophuthatswana will count separately from North Bophuthatswana, so work all the H5s you hear until you are sure you have them both. ZS6BOK/H5 was in South Bophuthatswana; H5AA was North.

IP5CJA, on during the WPX contest last March, was on Montecristo Island in the Tyrrhenian Sea, part of the Tuscan Archipelago. This is a wildlife conservancy like Desecheo Island and is administered by the Italian Department of the Interior. Only two operators are allowed on the island at once and for only four days. Although Montecristo Island would appear to qualify as a new country under the same "distinctively separate administration" that qualified Desecheo, the ARRL has so far rejected the Italians' claims.

W4BAA is looking to close out the logs for the 9L1JM operation from November, 1974, to September, 1978. The station has returned to Holland, so if you still need a QSL, it's now or forever hold your peace.

VQ9JJ and VQ9KK are on Diego Garcia for a long stay and plan to be active on 28545 kHz and 21352 kHz. QSL to W5RU.

That AX6 prefix marked the visit of Prince Charles to Western Australia on the 150th anniversary of settlement there in the old west.

Continued on page 158

New Products

DAIWA CN-720 SWR AND POWER METER

Take one look at the new Daiwa CN-720 swr and power meter and you'll realize that it's something unique among ham shack accessories. Unlike other meters, which display only one or two transmitter parameters, the CN-720 simultaneously displays three important quantities—forward power, reflected power, and swr—on a single dial face. Very convenient.

Actually, the concept of the Daiwa metering system is so simple that you'll wonder why someone didn't think of it before. Conventional units require the user to observe two different dial faces or else switch between functions in order to monitor two or more values. The Daiwa system puts two meter movements and three scales on the same dial face. The meter movements indicate forward and reflected power at the same time, which might seem like convenience enough, but Daiwa has gone a step further. In the area where the forward and reflected power pointers cross one another, there is a third scale designed to indicate swr. Simply note the point where the two pointers cross and swr can be read directly from the scale. Thus, you can monitor all three important quantities at the same time on one dial face. Believe me, this makes transmitter and antenna tuner adjustments a snap.

The front panel of the CN-720 contains a single control switch which is used to set the power range of the meter at 20, 200, or 1000 Watts. When rf is applied to the meter, one of three LED indicators is illuminated as a reminder of the power level you have selected.

The rear panel features three SO-239s for connection of the station transceiver along with two antennas (or one antenna and a dummy load). A built-in slide switch allows selection of either antenna without resorting to an external coax switch—a definite plus.

The CN-720 is housed in a rugged all-metal enclosure measuring 7" W x 4¾" H x 5" D. An electrically identical unit, Model CN-620, is available in a more compact case measuring 6½" W x 3" H x 3¾" D. Both units are rated for legal limit power from 1.8-150 MHz. All features of the CN-720 are retained in the 620—the only difference is the size. Those wanting a large, easy-to-read meter would probably choose the 720. Where small size and weight are important, the 620 is a better choice. Styling is a subjective factor, of course, but I find these meters very attractive; they should look good in most any ham shack. *J. W. Miller Division, Bell Industries, PO Box 5825, Compton CA 90224.* Reader Service number B47.

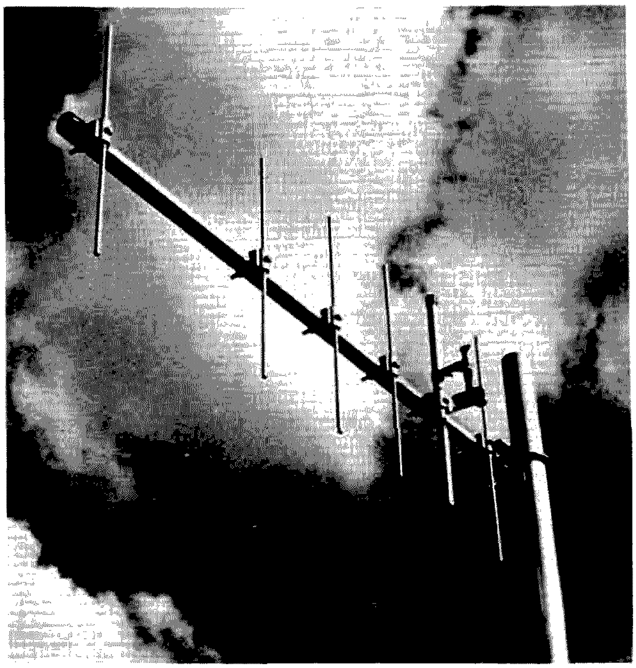
Assistant Publisher

BROADBAND UHF YAGIS

Cushcraft Corporation has announced 2 new broadband Proline 6-element yagis for UHF service. Both models offer 10-dBd forward gain, 20-dB front-to-back ratio, 10-MHz bandwidth, and 50-Ohm UHF connector termination. They come complete with hardware for versatile end-mount installations. Designated models P456-6 (450-460 MHz) and P467-6 (460-470 MHz), they require no tuning and are ideal for situations where relatively inexpensive yet durable antennas are required. For further information, contact *Cushcraft Corporation, PO Box 4680, Manchester NH 03108.* Reader Service number C67.

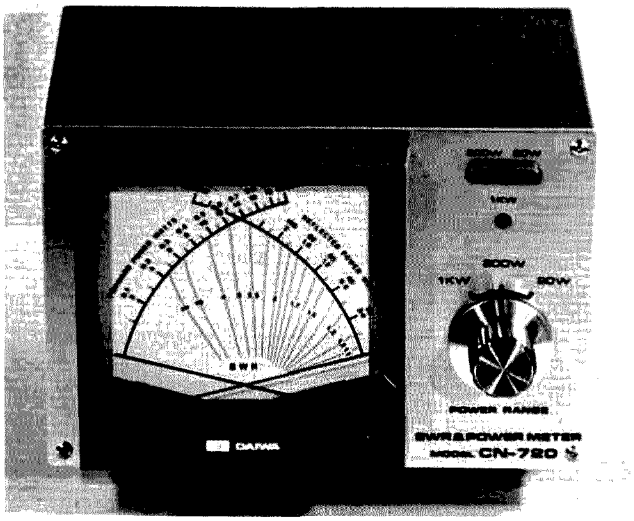


One of Cushcraft's new UHF yagis.

1.4-GHZ, 10-DIGIT FREQUENCY COUNTER

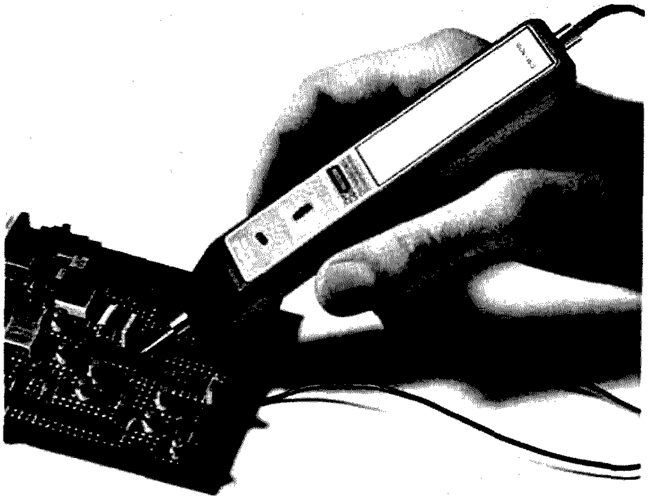
Optoelectronics, Inc., has just announced an all-new, top-of-the-line, ac-dc portable multifunction counter/timer. Dubbed the MCT 9010, this state-of-the-art unit has a most impressive list of features, all of which are standard, including a precision temperature-compensated 10-MHz crystal timebase (0.1 ppm, tcxo 17-40° C) with an aging rate of less than 1 ppm/year guaranteed, four functions (frequency, period, ratio, and totalize), 8 gate times from .01 second to 20 seconds, a low-frequency multiplier for resolution of .001 Hz below 5 kHz, resolution to 1 Hz through 1.4 GHz, and a variable sensitivity attenuator with a typical sensitivity of 1-20 mV rms from 10 Hz to 1 GHz.

Provided with each MCT 9010 will be a "Certificate of Compliance" certifying the timebase stability, aging, and NBS calibration traceability. For further information, contact *Optoelectronics, Inc., 5821 N.E. 14th Avenue, Ft. Lauderdale FL*

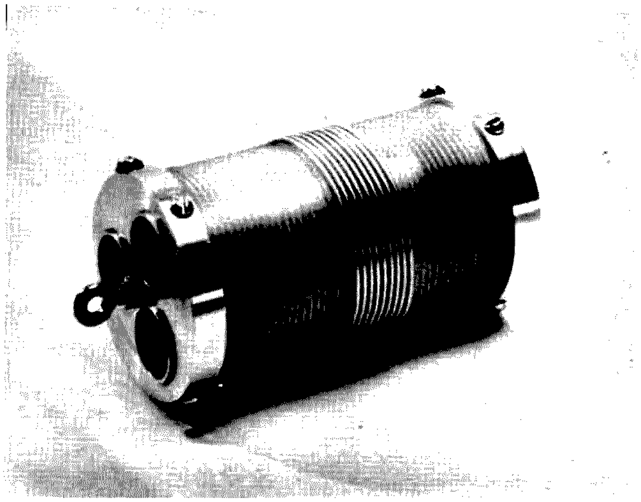


Daiwa's CN-720 swr and power meter.

Optoelectronics' MCT 9010 counter.



B&K-Precision's new digital pulser probe.



Unadilla's new KW-80 80-meter antenna trap.

33334; (305)-771-2050/1. Reader Service number O3.

MODEL HG-52SS CRANK-UP TOWER

Hy-Gain Electronics, a division of Telex Communications, Inc., has announced the Model HG-52 self-supporting tower. The HG-52SS is designed to support 9.0 sq. ft. of antenna area with winds up to 50 mph. This all-steel tower has the advantage of an improved guide system which allows the tubing to be open at each end, ensuring complete galvanizing and total moisture drainage.

The HG-52SS will accommodate standard rotators. A thrust bearing can be bolted to the top section to allow a 2-inch mast. For further information, contact *Hy-Gain Electronics, 8601 Northeast Hwy. 6, Lincoln NE 68505; (402)-467-5321.* Reader Service number H4.

NEW DIGITAL PULSER PROBE ANNOUNCED BY DYNASCAN

The B&K-Precision product group of Dynascan Corporation has just introduced a new digital pulser probe. The new unit, designated as Model DP-100, is designed as an aid to fast analysis and debugging of integrated circuit logic systems.

The DP-100 generates a single pulse in the "one-shot" mode or a 5-Hz pulse train in the continuous output mode. Simple to operate, the DP-100 can be used alone or in conjunction with a logic probe or oscilloscope. When the probe output is applied to a circuit, it will automatically pull an existing logic low to a high state or an existing high state to a low. By observing the change in circuit output, the user can isolate faulty circuits and components. Applied test energy is limited to only 0.33% of the normal power dissipation of a good device. This ensures that circuit damage cannot result from the DP-100 test procedure.

For full versatility, the DP-100 is compatible with DTL, TTL, RTL, and CMOS logic circuits. Operating power is derived from the circuit under test, so batteries are not required. Like other B&K-Precision products, the DP-100 is well protected against overvoltage or polarity reversal. The output (probe tip) is protected to ±35 volts and the input power leads are protected to ±160 V dc and 117 V ac.

For additional information, contact *B&K-Precision, Dynascan Corporation, 6460 West Cortland Street, Chicago IL 60635; (312)-889-9087.* Reader Service number B45.

80-METER ANTENNA TRAPS

Unadilla has added a pair of 80-meter antenna traps (the KW-80) to its line of 10-15-20-40-meter series. The KW-80 takes 1 kW, is weatherized, and is available for the CW band (KW-80C) or the phone band (KW-80F). For further information, contact *Microwave Filter Company, Inc., 6743 Kinne St., East Syracuse NY 13057; (315)-437-3953.* Reader Service number U9.

MODEL TH5DX FOR 10-15-20 METERS

Hy-Gain Electronics has introduced the newest member of its famous Thunderbird line of triband antennas. The TH5DX offers outstanding performance on 20, 15, and 10 meters. It features 5 elements on an 18-foot boom, with 3 active elements on 15 and 20 meters and 4 active elements on 10 meters. The TH5DX also features separate air-dielectric Hy-Q traps for each band. This allows the TH5DX to be set for the maximum F/B ratio and the minimum beamwidth possible for a triband antenna of this size. Also standard on this antenna are Hy-Gain's unique beta-match, rugged boom-to-mast bracket, taper-swaged elements, and Improved element compression clamps. For further information, contact *Hy-Gain Electronics, 8601 Northeast Hwy. 6, Lincoln NE 68505; (402)-467-5321.* Reader Service number H4.

Ham Help

As a radio amateur, I like very much to experiment and try different approaches to various problems. I am sure that there are more persons, in many fields, who are doing the same thing: experimenting with various facets of scientific problems in the hope of finding a better/cheaper/more-efficient way of doing things, or doing things that supposedly cannot be done.

At this time, there is an organization being started to bring together, in one group, various clubs and individuals who might be called amateur scientists. The organization is called, aptly enough, the Amateur Scientist Research Organization. Anyone interested can find out more by writing to ASRO, PO Box 4, McMechen WV 26040. We will be glad to send him the latest newsletter and bulletin. There is no charge or obligation.

Also, there is a net planned for the ham members. We feel that this organization fills a definite need in the world of the amateur scientist. We are open for suggestions from all persons.

Richard S. Meyer WD8BJW
134 Jims Run
McMechen WV 26040

I have a military surplus unit labeled TYPE CFN-46ADT RF TO IF CONVERTER, SERIAL 737, A unit of model BP Radio Eqpt., Navy Dept.—Bureau of Ships, Farnsworth TV & Radio Corp. I would appreciate any information on frequency coverage, i-f output frequency, voltages, etc. Many thanks.

J. O. Dickinson W4LLF
1408 Monmouth Court West
Richmond VA 23233

I will be visiting the United States and Canada for 3 weeks In August of this year, and I would like to meet local amateurs as I pass through. Having the equivalent of a Technician's callsign, I do not know many hams stateside.

Being originally from VU2, I shall be bringing along some slides on VU2 and ZL and will be happy to talk about them. I shall be spending a week each in Concord CA, Point Pleasant NJ, and Toronto, Canada, with no fixed plans, so I would appreciate advice on local attractions, 2-meter repeaters, ham shops, etc. (All letters will be answered.) I have also been a broadcast-band SWL for some years and would like to hear from SWLs, too.

Ashok Nallawalla
PO Box 144
Dunedin, New Zealand

I need a February, 1950, copy of *CQ* to copy an article. I will return it to the owner in good shape. Thank you.

2267 Star Route 183
Atwater OH 44201

Ham Help

I am interested in obtaining information on the World Radio Laboratories Model SB 175 transmitter. I am particularly interested in converting the DSB to SSB, and would also like to know about any other successful modifications that have been made to this unit.

I am also interested in obtaining a schematic on a digital frequency display for the FRG-7 receiver, using either an external frequency counter or a separate readout.

Rex D. Faulkner
3413 Covington Drive
Augusta GA 30909

I would like to get in touch with any hams who are interested in or own antique and classic cars, for the purpose of starting a classic car net on 15 meters. When writing, please list the car(s) (if any) you own.

Gary Carter WA4IAM
329 Oakdale Rd.
Rocky Mount NC 27801

I would like to get in contact with a ham in the Peoria, Illinois, area who could help me with code practice for my General ticket.

Patrick Butler
3208 W. Greenwood Pl.
Peoria IL 61615

Does anyone have a schematic for the Hallicrafters T.T.O. Electronic Keyer, Model HA-4? I will gladly pay copying cost and postage.

Bill Hurt WD4RMA
Rt. 1, Box 212A
Zirconia NC 28790

Anyone interested in starting an informal net for hunters, shooters, and fishermen on about 21,400-410 MHz daily at 1500Z? Drop me a card or meet on frequency.

Art Santella K1VKO
43 Seaview Ave.
East Norwalk CT 06855

I am interested in becoming a QSL manager for any DX station.

Dennis Younker WA6OYV
45255 Raysack, Apt. 2
Lancaster CA 93534

I am trying to make a Gonset GSB-2 Model 900B with a Model 901A work again.

I need a manual, a schematic, and alignment info.

I will be glad to pay any reasonable cost for copies and mailing. Thank You.

R. Maag K6IUP
40103 87th St. W.
Leona Valley CA 93550

I am very curious to know if there exists an unconverted, untampered with, working or not, Motorola HT-220 for sale which costs less than the national debt.

David Pilipauskas WB9HPJ
6649 S. Fairfield
Chicago IL 60629

I would like to purchase a manual or schematic for a Kaar UHF transceiver (model 12TR510A), which I plan to convert to 440 MHz. The manufacturer is no longer in business.

Norris Saari W7LAP
13535 53rd Ave. So.
Seattle WA 98168

I would like to hear from anyone using the new Atlas RX-110 and TX-110L combination. I'm interested in the comments and experiences of others who are using this setup.

Keith Arnold N8AQR
1273 Erickson Ave.
Columbus OH 43227

Social Events

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

UPPER HUTT NZ
JUN 1-4

The 1979 Annual Conference of the New Zealand Association of Radio Transmitters will be held on June 1-4, 1979, at Upper Hutt, New Zealand. Visitors are welcome to attend this conference. For registration forms, contact the Secretary, 1979 Conference Committee, PO Box 40-212, Upper Hutt NZ.

ST. PAUL MN
JUN 2

The North Area Repeater Association, Inc., will hold its Amateur Fair '79 on Saturday, June 2, 1979, at the Minnesota State Fairgrounds, St. Paul, Minnesota. This is a swapfest and exposition for amateur radio operators and computer hobbyists. There will be free overnight parking for self-contained campers on June 1st only. You may sell from your car in the giant flea market or from the available inside space. There will be AMSAT and microprocessor exhibits, FCC, ARRL, Minnesota Repeater Council booths, and many prizes. Admission is $2.00. For information or reservations for commercial space, write Amateur Fair, PO Box 30054, St. Paul MN 55175.

WENATCHEE WA
JUN 2-3

The Apple City Amateur Radio club will hold its Ham Fest on June 2-3, 1979, at Rocky Reach Dam, 7 miles north of the city on Highway 97, Wenatchee, Washington. Registration fee for amateurs is $3.00 (which includes one ticket for the prize drawing), $1.00 for non-amateurs, and children under 12 are free. A banquet dinner will be held on Saturday night at $5.00 per person. Free camp/trailer space will be provided at the park. Featured will be equipment displays, a VHF tune-up clinic, an arts and crafts show/sale, a swap shop, a photography display, exhibits, a tour of the Power House, a film on the Life of Thomas Edison, and a potluck dinner on Sunday at 1:00 pm. For information and reservations, contact the Apple City Amateur Radio Club, 713 Grandview Avenue, Wenatchee WA 98801.

ISLIP LI NY
JUN 3

The Long Island Mobile Amateur Radio Club, Inc., will hold its Long Island Hamfair '79 on June 3, 1979, from 9:00 am to 4:00 pm at the Islip Speedway, on Islip Avenue (Rte. 111), just one block south of the Southern State Parkway, Exit 43, or south on 111 from Exit 56 of the Long Island Expressway, Islip, Long Island, New York. There will be over 250 exhibitors. General admission is $1.50 and exhibitors' admission is $3.00 per space. Wives, sweethearts, and children under 12 are admitted free. There will be many door prizes available for all ticket holders. Talk-in on 146.25/.85 and .52. The rain date

Add Digital Display for $50

—100-Hz accuracy

A useful addition to your shack.

Richard C. Jaeger K4IQJ
1599 Gonzalo Road
Boca Raton FL 33432

Several years ago, I decided that a digital readout for my R4B receiver would be a worthwhile addition to my shack. After reviewing existing articles describing counters and vfo readouts, the counter in Fig. 1 was designed, which was similar to one described in *Ham Radio.*[1]

Only the vfo signal is measured, which avoids the complexity of sequentially measuring the frequency of several oscillators. The signal from the vfo in the R4B, which tunes from 5445 kHz down to 4995 kHz, was mixed in a digital mixer (7474) with the output of a crystal oscillator at 5445 kHz, to produce a difference signal in the range of 0-500 kHz.

Since I wanted the ability to accurately calibrate the display, a variable capacitor was used to adjust the frequency of the crystal oscillator which fed the digital mixer, so that the counter could be adjusted to zero on each band. The output of the mixer was fed to the counting circuitry, which displayed a three-digit count (10 kHz, 1 kHz, 100 Hz) fifty times per second. A 50-Hz flicker rate in the LED display is not detectable by the eye, and eliminates the need for latches between the output of the decade counters and the seven-segment decoder-drivers.

After using this readout for over six months, I decided that the overall performance was not satisfactory. First, the three digits did not display sufficient information. I found that I was constantly referring to the receiver dial to determine in which 100-kHz band segment I was operating. Second, since the basic count interval was 10 ms, and the counter was not synchronized to the input signal, the low-order digit flickered annoyingly between two values. Finally, the frequency adjustment obtained with the simple variable crystal oscillator was not sufficient to cover the variation in hfo mixer crystals in the receiver. So, a second design was undertaken with the aim of correcting the faults which had become apparent in the existing display.

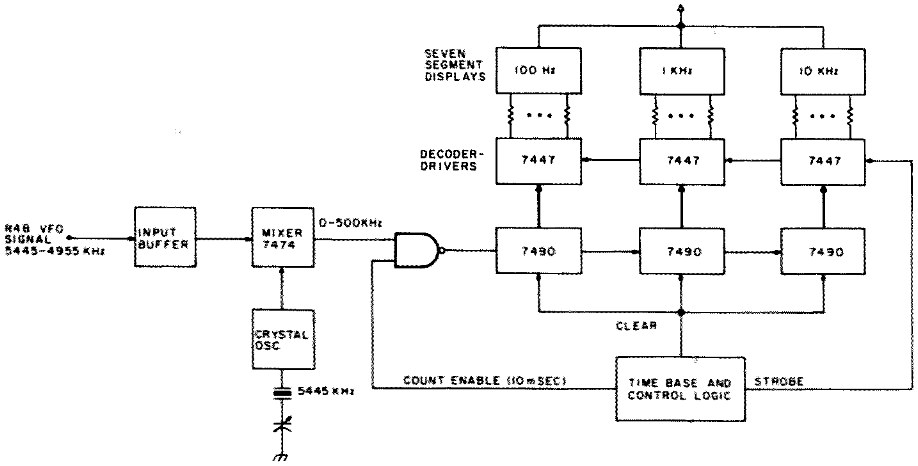

Fig. 1. Block diagram of the first digital readout.

The new version of the display corrects the problems discussed above, and can be built for less than $50 if all of the parts are purchased new. The display was designed with four digits and 100-Hz resolution, as shown in the block diagram of Fig. 2. The incoming signal is first divided by ten, and the basic count interval increased to 100 ms, to eliminate the flicker in the last digit.

After some thought, I realized that mixing the vfo signal to produce the 0-500-kHz signal represented unneeded complexity. Measurement of the vfo

signal could be done directly by simply down-counting or subtracting, rather than counting upward in the counters. To accomplish this, presettable down-counters (74192s) are used and preset to 455.0. When the signal from the vfo at 5455.0 is subtracted from this count, the correct reading of 000.0 is displayed in the lower four digits. The most significant digit is dropped. When the vfo is tuned to 4955.0, the display will show 500.0 kHz. To display readings corresponding to 500.0 to 999.9, the preset count is changed to 955.0. Circuitry for the counter and display is shown in Fig. 3.

Using the presettable down-counters also solves the problem of how to calibrate the readout. Instead of presetting the two low-order digits to fixed values, the preset values are determined by the contents of two additional decade counters (7490s). The contents of these two counters may be altered by simply pulsing their inputs until the preset is correct to calibrate the counter. The preset value in these two digits ranges from 0.0 to 9.9, corresponding to an adjustment range of −5 kHz and +4.9 kHz about the nominal frequency. This range represents a sufficient adjustment range for the crystals used in the receiver and corresponds to approximately a 0.01% or greater tolerance on the mixer crystals used in the R4B receiver. In the digital readout for the R4B, the third digit is always preset to the value 5. The fourth digit is preset to either 4 or 9, depending upon which 500-kHz segment is being used, and is selected by a front panel switch.

The vfo range and preset number are also shown in Table 1 for other rigs which were available to me. The

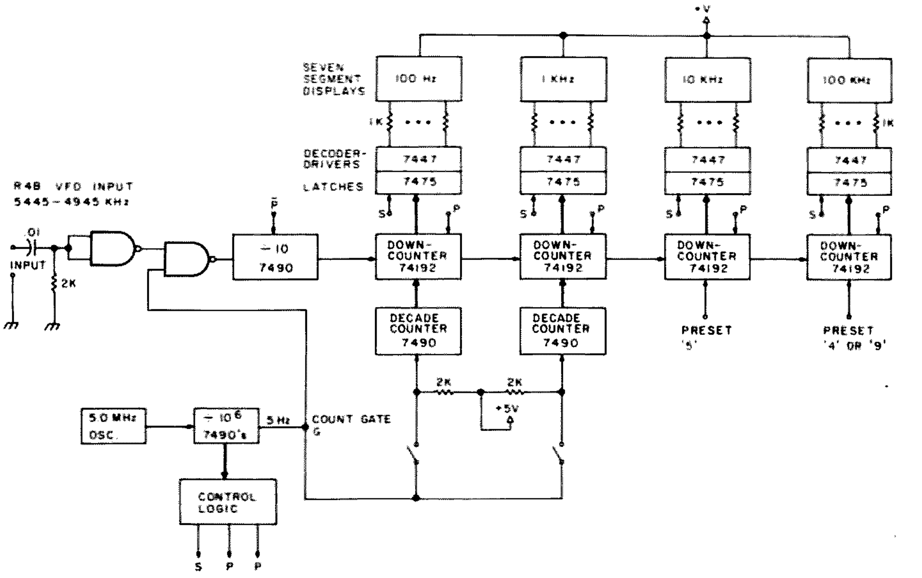

Fig. 2. Block diagram of an improved digital readout. G = count gate; S = strobe for 7475; P = preset for counters.

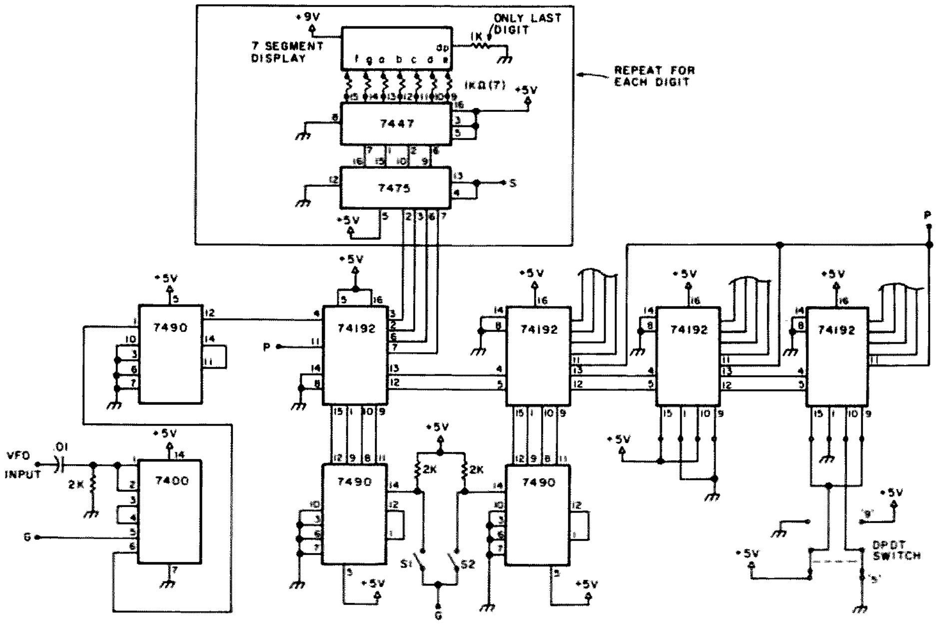

Fig. 3. Counter, display, and display drivers.

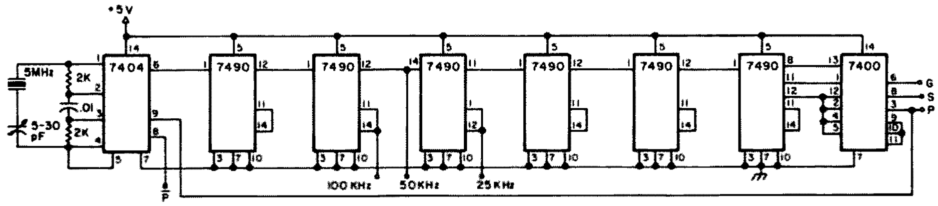

Fig. 4. Timebase and control signal generator.

Heath line of vfos do not have the convenient 5-kHz offset. However, switch-selectable preset can easily be added to the third digit of the counter. It should also be possible to shift the heterodyne oscillator crystals with a capacitor, in order to ensure that an offset always exists. A third alternative is to replace the oscillator crystals with new ones offset by 5 kHz.

The timebase circuitry (Fig. 4) is of straightforward design. A counter chain

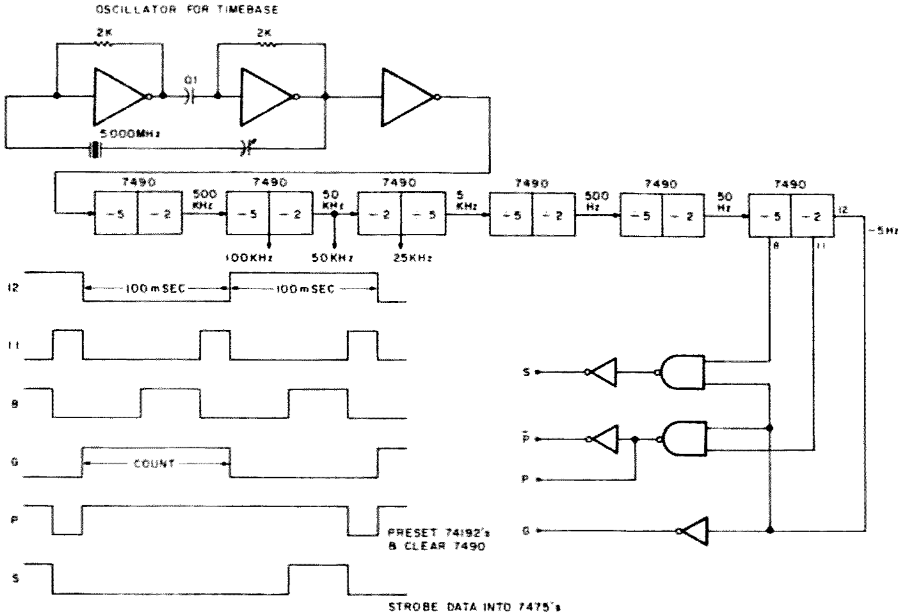

Fig. 5. Timebase and control logic for the digital readout.

divides the output of a 5-MHz oscillator down to 5 Hz. One intermediate divider stage is wired in divide-by-two, divide-by-five fashion, so that 100-kHz, 50-kHz, and 25-kHz outputs are available and may be switch-selected for calibrator purposes, if desired.

The control signals were designed to be of minimum complexity. As shown in Fig. 5, the timebase output is a signal with a 200-ms period. During one 100-ms period, the contents of the counter are gated to the display latches, and continuously displayed on the seven-segment displays. The preset values are then gated into the counters, and the counter is ready to measure the input signal. During the next 100-ms period, the counters are decremented by the input signal, and the cycle then repeats itself.

The vfo signal from the R4B is obtained at the output of the low-pass filter (C132, L6, C149) which is connected to the output of the vfo unit as shown in Fig. 6. The signal is tapped off at the junction of C149 and L6 through a .01-uF capacitor. An attachment is made to the circuit board mounted directly behind the af gain control, and the wire is routed along the side of the chassis to a phono socket installed in the spare position on the back of the R4B.

The digital readout was packaged with its power supply in a small cabinet. The power supply (Fig. 7) uses a full-wave bridge rectifier with a capacitive filter, followed by an LM309 5-volt regulator. The seven-segment displays do not require regulated voltage, and the display drivers (7447) can use a segment supply of up to 15 volts. Power for the seven-segment displays is therefore tapped off ahead of the regulator, in order to minimize dissipation in the regulator. The filter capacitors were chosen to maximize the ripple at the regulator input, while ensuring that the regulator does not drop out of regulation. This can be done easily using an oscilloscope, and also minimizes regulator dissipation. The displays are mounted in a socket assembly and bezel unit which adds immeasurably to the overall appearance of the display.

A toggle switch selects either a 0-500.0 or 500.0-999.9 display. Two pushbuttons are used to calibrate the two low-order digits of the display. Calibration is accomplished by first adjusting the receiver to zero-beat with the calibrator signal. This can be done quite accurately by watching the S-meter as the receiver is adjusted to zero-beat. At zero-beat, the S-meter needle will waver back and forth at a low frequency. After the receiver is adjusted to zero-beat, the two buttons on the readout are depressed until the readout displays the correct frequency. One will get the hang of this adjustment after a little practice. The calibration obtained is well within the 100-Hz resolution of the readout, and the display accurately reads out the frequency to which the receiver is tuned to within 100 Hz. The stability of the timebase in the counter has been found to be more than adequate for this resolution. Drift of the timebase has been measured to be less than 100 Hz from a cold start.

This version of the readout has been in use now for approximately two years, and has proved to be a useful addition to the shack. The display permits an accurate QSY, allowing one to return to the exact frequency of a desired station during contests or when chasing DX. The calibration feature also allows the offset associated with CW reception (100-1000-Hz) to be removed, so that the display indicates the frequency of the received signal directly.■

High-Performance Receiver Add-Ons

—aren't ICs wonderful?

New circuits and ICs improve performance.

Howard J. Sartori W5DA
PO Box 2085
Richardson TX 75080

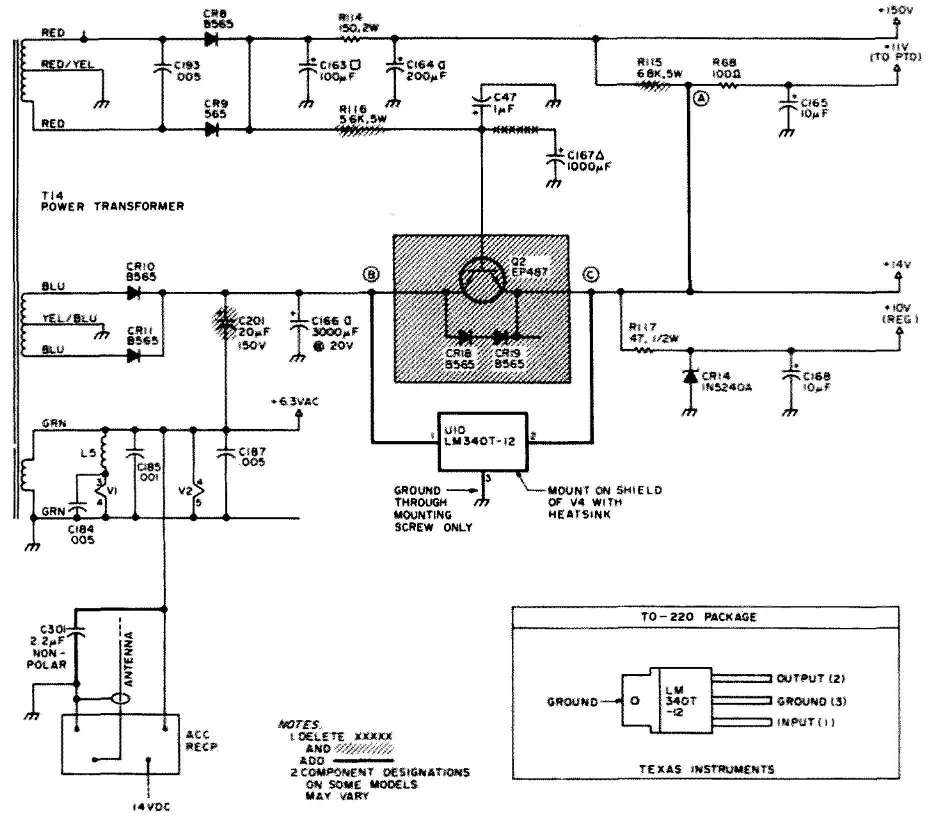

Fig. 1. A simple three-terminal integrated circuit regulator can easily be added to almost any receiver low-voltage supply to improve hum, ripple, and circuit decoupling. The example circuit is taken from the Drake R-4C.

Modern receiver equipment designs often become obsolete before they can be manufactured, tested, and sold. Unfortunately, highly-reliable printed circuit boards almost freeze the performance design of many solid-state receivers. Some of the more exotic, sophisticated technologies are difficult to add to miniaturized solid-state receivers or transceivers. Marketing policies don't make a printed circuit board substitution upgrade possible. But, within the decade, the increasing costs of receivers will make this a very profitable market either for original manufacturers or for small specialty-electronics firms. One of the really big advantages of vacuum-tube equipment is that usually the normally spacious layout permits easy maintenance as well as "graceful" upgrading in the ham shack.

Several field changes that utilize new high-performance components and circuit concepts are described in this article.

Some of them are not even standard equipment in the latest off-the-shelf solid-state receivers. For example, a high-performance, wide dynamic range, doubly-balanced modulator with all of the adjustments factory-set within the device can be added very easily to almost any receiver. The popular Drake R-4B and R-4C radio receivers are used as typical examples of how older receiver performance can be upgraded by simple field changes. Greater local oscillator suppression, better crystal filter floors, and a wide dynamic range product detector are among the easy-to-make changes that produce a big difference in performance. None of the field-change improvements takes over 45 minutes to incorporate.

Low-voltage Power Supply

A miniature, 3-terminal, integrated circuit, 12-volt regulator can replace the high-voltage (150 V dc) drop-down sources while greatly improving the hum and rectifier hash noise. The lower source impedance of an electronic regulator can improve distortion problems. A big improvement for Drake equipment is the removal of the drop-down resistors and transformer which produce 15 Watts of heat. This improvement will increase the component reliability of the receiver, and will also reduce vfo drift.

Presently, the 11 volts is obtained through a power-dropping resistor from the 150-volt line. A reference source for the 14-volt line is obtained through another power-dropping resistor from the 150 volts. A capacitance-multiplying transistor circuit smooths the 14 volts, but the ripple output is still greater than 50 millivolts on many power supplies.

The three-terminal voltage regulator reduces the ripple and hash to less than 2 millivolts.

At a cost of less than $3, the change takes only 45 minutes to make. Refer to Fig. 1. Here are the procedures:

1. Install the 3-terminal LM340T-12 voltage regulator (manufactured by either TI or National) on the third mixer, V4 (6EJ7), shield just above and on the same side as pin 9 of the tube socket. Use a small general-purpose finned heat sink mounted under the integrated circuit tab. Drill a 9/32" hole and use 6-32 hardware.

2. Remove these parts:
Q2—EP-487, regulator transistor;
CR18/19—B565, rectifiers;
C201—20 uF, electrolytic capacitor;
R115—6,800 Ohm, 5-Watt resistor;
R116—5,600 Ohm, 5-Watt resistor. Note the location of the bottom hole (chassis end) where the resistor is removed, labeled point "A" in Fig. 1; you'll need it later.
The wire to C167Δ, 1000-uF electrolytic capacitor (marked C166 on some schematics).

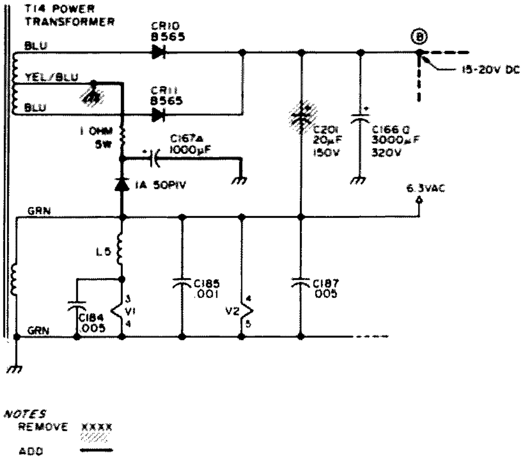

Fig. 2. If the low-voltage winding doesn't provide enough voltage to the integrated circuit voltage regulator, the 6.3 V ac filament winding can be used with a simple half-wave rectifier to boost the voltage.

Caution: Stay away from the upper holes where the power resistors were removed. Accidental connection to this 150-volt line can cause damage!

3. Wire point "B" at the dc input of the old Q2 regulator to the new regulator input, pin 1.

4. Wire point "C" at the dc output of the old Q2 regulator to the new regulator output, pin 2. (Ground is made through the integrated circuit tab.)

5. Jumper wire from the marked bottom hole of the old power resistor, R115 (6,800 Ohm), point "A" to the "+14 V" (now +12 V) bus point where all of the red wires are terminated. This step connects the 11 V line to the new +12 V line. The circuit impedance is now low enough to prevent any interaction.

6. Add a 2.2 uF non-polarized capacitor (25-volt minimum) across the filament socket as shown in Fig. 1.

7. Check the voltages listed in Table 1 after visually confirming the wiring.

If the existing low-

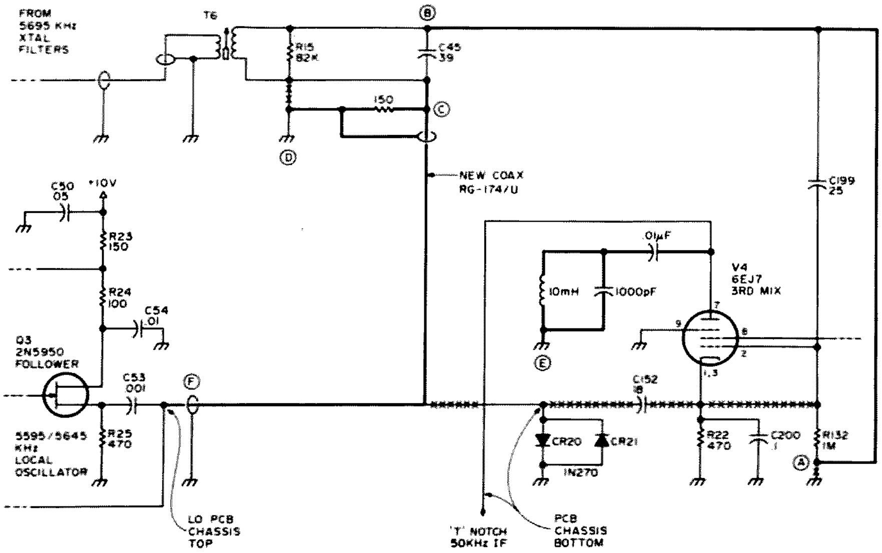

Fig. 3. Proper signal and LO feed and termination techniques are applied to the Drake R-4C receiver third mixer.

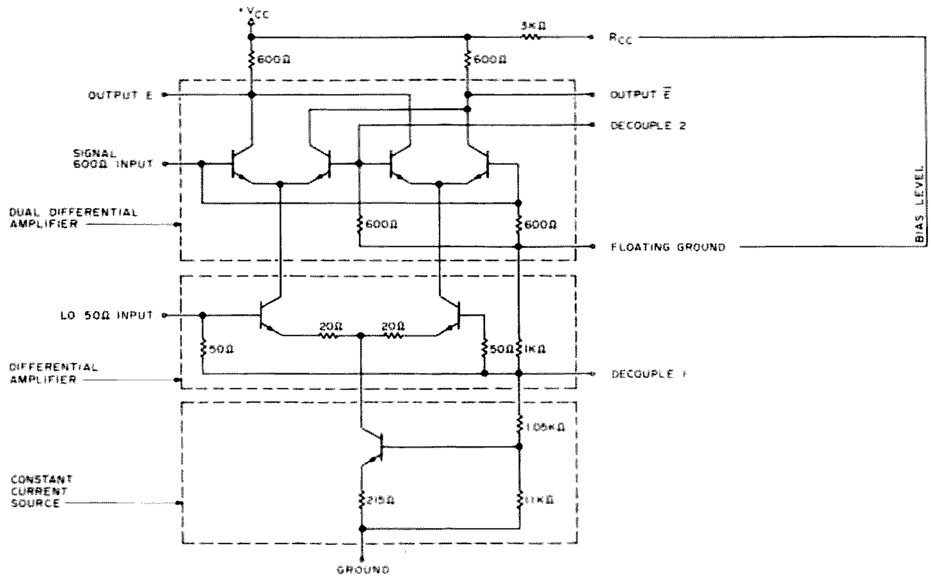

Fig. 4. Diagram of the ready-to-use TL442 doubly-balanced mixer/modulator shows the internal functions which require no external controls or additional circuitry.

voltage transformer winding doesn't provide at least 15 volts, then the 6.3 V ac section of the filament winding can be used to boost the voltage to the regulator. Fig. 2 shows how to bootstrap the 6.3 V ac filament line to the center tap of the low-voltage winding through the use of a simple half-wave rectifier. The unused C167Δ, 1000-uF filter capacitor provides sufficient filtering. The integrated circuit does the rest. If the voltage input to the regulator is too high, additional heat sinking may be required.

Mixer LO and Signal Feeding

Mixers are the first place where receiver performance falls short of our expectations. If the mixer is ahead of the filters, then third-order interference is created within the amateur bands. Specified as "dynamic range," this is probably the most stringent receiver specification. If the mixer is after the filters, then problems can still arise due to the same causes, except for one: The LO is not radiated back through the rf amplifier to the antenna to interfere with other radio services. And, if an audio filter is used for CW, then the dynamic range of the last mixer is not too important. However, when the LO is radiated back into the i-f or amplified without attenuation at the mixer output, then the probability that spurious responses in the receiver will be generated greatly increases. The same principles apply to the i-f signal driving the mixer, as far as reducing the output of this signal at the mixer output.

A modern solution available is to use doubly-balanced modulators to attenuate each signal at any input or output, with only the conversion signal appearing at the output. However, in practice, the bipolar balanced mixers I measured offer about 10-dB poorer dynamic range performance than MOSFETs and vacuum tubes under optimum circuit conditions. Then the only really strong case for a balanced mixer is where the signal or LO are so close in frequency to each other in the mixer output that a tuned circuit cannot discriminate against the amplified LO and signal input.

Balanced mixers do solve the spurious signal problem. However, many tests that I conducted with single versus dual-input circuits (such as a dual-gate MOSFET) have shown that the noise figure and dynamic range performance are about the same either way.

The primary factor in good mixer performance is a strong LO signal on the order of 250 mV for either a vacuum tube or a dual-gate MOSFET, fed either singly or with dual inputs. The dynamic range tends to be proportional to the gain of the particular device. Beyond these good design practices, an order-

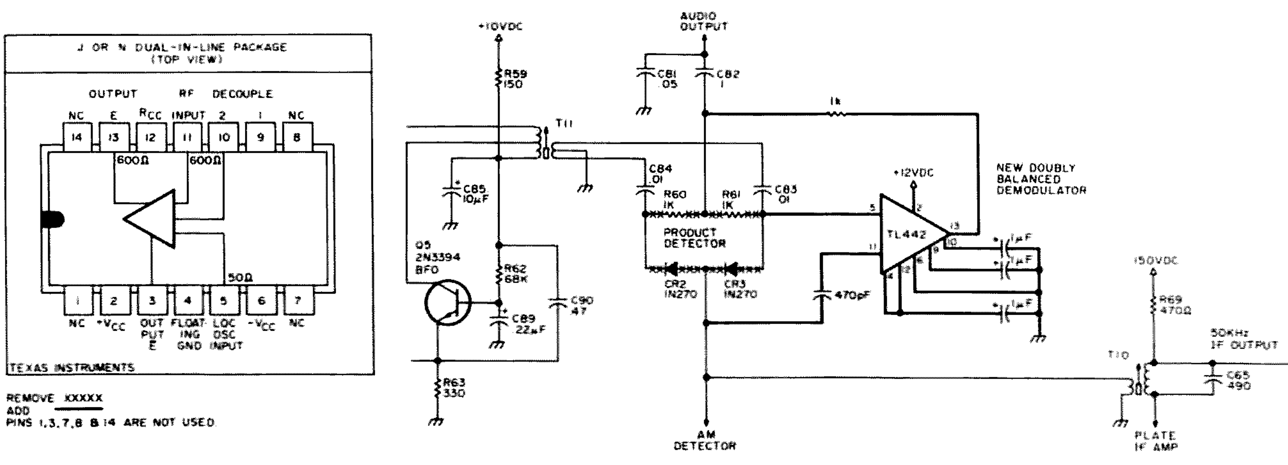

Fig. 5. A communications doubly-balanced modulator/demodulator is applied to the Drake R-4C receiver with a minimum of additional parts. No printed circuit board is needed.

of-magnitude increase in sophistication of circuitry is required.

The third mixer in the Drake R-4C was chosen to demonstrate how to apply proper feed and termination principles to a mixer. As a result, the LO and signal radiation was reduced. And, the crystal-filter rejection floor was lowered by reducing ground loop radiation. Fig. 3 shows the circuit before and after the improvements. Note that the original circuit provided a capacitive divider voltage step-up from the LO output at point "F" to the crystal-filter transformer at point "B" to enhance undesired radiation. Both the signal and the LO signals are terminated in several ground returns at the transformer, T6, grid-leak resistor R132, and limiting diodes CR20/21.

Good principles of mixer feeding were applied. First, the signal was fed with the grid-leak resistor in parallel with the coupling capacitor, thus eliminating this ground loop. Then the LO was fed in series with the signal transformer, T6. Therefore, the LO signal could not be increased, and, furthermore, the LO signal is not impressed across the secondary of the signal transformer, T6.

A 150-Ohm resistor is used to terminate and limit the LO voltage output while not enhancing harmonic generation. Finally, a tuned circuit is connected to the output of the mixer to reduce the LO and input signal by about 20 dB. As a result, the signal rejection floor of the crystal filter is reduced by more than 15 dB, and the broadband white noise is greatly reduced in the SSB mode while only slightly degrading the narrow-band CW mode of operation. Here is the procedure for incorporating this field change:

1. Disconnect the 1-megohm grid-leak resistor, R132, from ground at point "A". Bend it over and reconnect to the output terminal of the i-f transformer, T6, at point "B". It will be in parallel with the 25-pF coupling capacitor, C199.
2. Remove the 18-pF LO coupling capacitor, C52, from the printed circuit board on the bottom near the chassis to the grid at pin 2 of V4, the 6EJ7 mixer.
3. Remove the LO coax from point "F" on the LO printed circuit board on the top side of the chassis to the printed circuit board on the bottom of the chassis.
4. Separate the ground lug at point "D" from the bottom end of the i-f transformer, T6, pin by about 3/8 of an inch.
5. Connect the LO from point "F" (where the coax was just removed) with miniature coax through the same chassis hole, routing along the output (power transformer side) of the tube socket to the i-f transformer, T6. Connect the center conductor to the bottom terminal at point "C" of the transformer, T6. Connect the shield to the ground lug at point "D".
6. Install a new 150-Ohm resistor from the bottom end of the i-f transformer, T6, at point "C", to the ground lug at point "D".
7. Install the 50-kHz parallel-tuned circuit (10-mH miniature molded choke in parallel with a 1000-pF mica capacitor) in series with a 0.01-uF 500-volt disc coupling capacitor from the mixer, V4, plate, pin 7, to the ground lug (next to pin 9) below the power transformer at point "E".
8. Turn on the set after visually confirming the circuit wiring. Tune in a signal to zero beat and retune the i-f transformer, T6, for maximum signal.

Doubly-balanced Demodulator

Finally, a very high-performance communications doubly-balanced modulator is easily substituted for the dual-diode detector. The TL442 was specifically designed for communications applications by providing factory-preset null adjustments internal to the integrated circuit. Signal and LO balanced nulls are greater than 30 dB. In some of the R-4C receivers, the LO input to the first audio amplifier at the top of the volume potentiometer was about 100 millivolts compared with an audio component of just several millivolts. Fig. 4 shows a diagram of the Texas Instruments TL442 (old designation SN76514) integrated circuit. Design features:

1. factory-tuned null adjustments for both signal and local oscillator;
2. noise figure of approximately 6 dB;
3. typical conversion gain of 14 dB;
4. low standard-communication circuit input/output impedances with virtually no reactive components at HF frequencies; and
5. flat frequency response to 100 MHz, with tuning usable to 300 MHz; C_{in} = 3-5 pF and C_{out} = 10 pF.

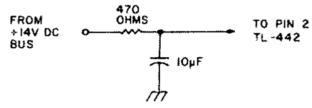

Fig. 6. Decoupling circuit required when 3-terminal regulator is not used.

UHF transistor chips are matched and the resistors are etch-trimmed in the manufacturing process to achieve balanced circuits. The IC actually consists of two cross-coupled differential amplifiers whose emitters are driven by a third differential amplifier. A constant-current source is connected to the bottom

Voltage	Location	Value before	Value after
Dc input	Regulator input, pin 1	17 V dc, 300 mV ac	16 V dc, 200 mV ac
Dc output	Regulator output, pin 2 and output bus	15 V dc, 42 mV ac	12 V dc, <1 mV ac

Table 1.

(third) differential amplifier. This device works best with 200-300 mV local oscillator injection, and performs without significant overloading up to about 500 mV of i-f signal input. Hence, the signal handling characteristics of the TL442 are as good as or better than most vacuum-tube converters in current receiver designs.

For example, a two-tone test with 20-kHz separation showed that the third-order intermodulation products 20 kHz above the upper frequency signal (or 20 kHz below the lower frequency signal) were more than 75 dB below the two-tone signal level. Since the tests were conducted at 6 MHz, the performance would be expected to be somewhat better at the 50-kHz i-f frequency. Normally, the dynamic range of the audio detector is not too important as long as distortion is reasonably low, but, when audio CW filters are used, dynamic range becomes important again.

An excellent description of the TL442 is also available from Texas Instruments.[1] Cost of the doubly-balanced mixer is about $3.00, an excellent trade-off when you consider that no external tuning or bias components are required for this application.

The application of the doubly-balanced demodulator to a receiver is shown in Fig. 5. When a 3-terminal voltage regulator is not used, the decoupling circuit shown in Fig. 6 may be required. Therefore, the load on the last i-f transformer is still maintained at about 4000 Ohms and the avc action is not affected. Normal i-f input to the IC with the avc "on" is about 10 to 30 mV. The LO is connected to the 50-Ohm IC input to reduce loading on the 50-kHz local oscillator. About 125 mV are available at the IC input. The procedures for installation of the doubly-balanced demodulator are:

12 V dc regulator
LM340T-12
Heat sink, Calectro CAT No. J4-866
Hookup wire
6/32 x 1/2 screw
6/32 lock washer
6/32 nut
2.2-uF, non-polarized capacitor
Note: for early R-4C receivers, 1 Amp 50 piv diode (not supplied)

Third mixer
10-mH choke
0.01-uF disc capacitor
1000-pF silver mica capacitor
150-Ohm resistor
12" RG-174/U coax

Doubly-balanced demodulator (product detector)
TL442
3 1.0-uF, 25 V dc tantalum capacitors
1000-Ohm resistor
470-pF disc capacitor
Hookup wire

Audio distortion correction
(thanks to R. J. Sherwood, *Ham Radio*, Dec., 1977)
0.0015-uF disc capacitor
4700-Ohm resistor

Cost: $15.00. Add 5% tax in Texas: 0.75. Shipping/handling: 0.60. Total ____. Mail check or money order to: Sartori Associates, W5DA, PO Box 2085, Richardson TX 75080.

Table 2. As many parts are hard to obtain, the author will supply parts as listed here.

1. Mount the IC "dead-bug"-style (leads up with double-stick tape) on the chassis between the bfo transformer, T11, and the bfo tuning capacitor. An alternative mounting location is the back side of the bfo capacitor. Then simply wire in the leads to the printed circuit board.

2. Connect bias pins 4 and 12 together.

3. Connect pin 6 to a ground point. Then wire all three of the bypass capacitors from pins 4 and 12, 9, and 10 to the same ground point. The values of the 1.0 uF capacitors are not critical, but must bypass both audio and i-f signal components. Miniature ceramic or tantalum electrolytics with at least 10 V dc breakdown are adequate. Connect pin 2, the 12-volt input, to the 14 V dc bus line.

4. To connect the LO input, first lift the 1000-Ohm product detector resistors (R60, R61) off the printed circuit board. Then, connect a wire from one of the C84/R60 or C83/R61 junctions to the LO input of the IC at pin 5.

5. To connect the i-f input, lift the product detector diodes (CR2, CR3) off the printed circuit board at the i-f input junction point. Connect a 470-pF decoupling capacitor from this junction point to the IC i-f input, pin 11.

6. Connect output, pin 13, to the junction of old R60/R61 resistors. The result of the doubly-balanced demodulator addition is cleaner audio over a much larger signal range, particularly in the avc "off" position. Further, the frequency tuning tolerance for SSB signals is wider. Audio output is increased about 5 dB as a by-product. The low output impedance of the integrated circuit makes the audio amplifier less susceptible to hum and other spurious pickup.

Acknowledgements

Assistance and suggestions in applying and evaluating the performance of these receiver improvements are gratefully accorded to Jack Whitaker W5HEZ, Rob Sherwood WBØJGP, and the several members of the Richardson Wireless Klub. I can supply a parts kit for these changes at a cost of $15.60 postage paid.■

The audio improvement offered by reference 3 is most important. However, in many receivers, parasitic oscillations occur in the several-hundred-Hertz range, and the addition of a 0.0015 uF capacitor across *resistor* R83 *in* the audio amplifier did not entirely eliminate them. To completely correct the phase error in the feedback circuit, eliminate an undesirable peak in the audio frequency response, and eliminate the spurious oscillations, a 4700-Ohm resistor needs to be added in series with the 0.0015 uF capacitor across resistor R83.

A Solution to the Home-Brew Housing Shortage

—building a box for your next project

Custom configurations are no problem.

Weldon I. Hogie W0IHI
615 E. 7th Street
Northfield MN 55057

One of the problems encountered by the home-brew addict is how to package his latest project. With a well-stocked junk box, he may find that the cabinet he prefers costs more than all the parts put into it. Also, even if cost is not a concern, the closest-size commercial cabinet may not have exactly the most desirable configuration.

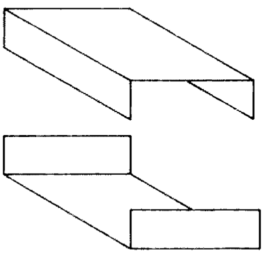

Fig. 1.

It is not too difficult to bend up your own simple cabinet with two U-shaped pieces (double clamshell rotated 90°) as shown in Fig. 1, but there is a limit to accessibility once everything is installed. If a printed circuit board is mounted above the inside of the bottom clamshell, for instance, the board must be removed or tilted away to get at the trace side. Also, unless heavy-duty bending equipment is available so that you can use quite thick material, rigidity leaves much to be desired. This article proposes a method of custom-building your own enclosure in any dimension or configuration desired. The main features are complete accessibility to the interior, excellent rigidity when the covers are removed, and reasonable cost.

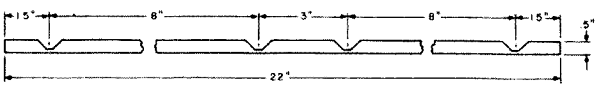

Fig. 2.

Let's Build One

To use an example: Let's build an enclosure 3″ high by 6″ wide and 8″ deep, suitable for an electronic counter, for instance. Obtain a 5- or 6-foot length of aluminum angle material which is 1/2″ on a side and 1/16″ thick. This aluminum angle is generally available in hardware or building supply stores in a display containing various types of aluminum rods, straps, tubes, angles, and decorative sheets.

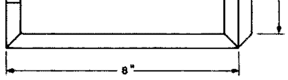

Fig. 3.

Cut two pieces, each 22″ long. Scribe and cut four 90° notches in one side of each of the 22″ lengths, as shown in Fig. 2. Use a hacksaw to cut and a file to smooth up the notches. Now, carefully bend 90° at each notch so you end up with two identical rectangular pieces like the one shown in Fig. 3. These are the side rails. You can bend this material only once, so do it right the first time. You may want to practice on some short lengths of angle before starting on the 22″ lengths.

Cut two pieces of .06″ aluminum sheet 3″ by 6″ for the front and back panels. (Or cut 3-1/16″ by 6″—see *Note* in the section "Cover It Up" below). You could use .05″ sheet, but .06″ is surprisingly more sturdy and not that much more difficult to work with. Fasten the 3″ by 6″ plates to the side rails as shown in Fig. 4 and you

have a very sturdy enclosure ready for stuffing.

The leftover lengths of aluminum angle can now be used to make mounting surfaces inside the enclosure by attaching to the side rails and front and back panels. By cutting off short 1/2" lengths of the angle material, handy little mounting angles can be made to help in fastening the mounting surfaces. When fastening to the rails, use 4/40 or 4/36 flathead screws, countersunk, in order to retain the flat outer surfaces of the rails to help in fitting covers. (Handy hint! Obtain a 1/4" machinist's center drill used by metal lathe operators. It will drill a no. 4 clearance hole and countersink it in one operation. I always keep one handy on the bench, mounted in a handle, for quick deburring and countersinking.)

Larger Enclosures

Look for 3/4" by 1/16" or 1" by 1/16" angle material. Larger enclosures can be fabricated using this wider stock, and good rigidity will still be maintained. The 3/4" by 1/8" angle should also be considered if an exceptionally strong enclosure is desired. While the 1/8" angle is too thick to notch and bend as with the 1/16", suitable lengths can be cut to 45° on each end and fastened together with 90° angle plates or brackets placed inside the rails as shown in Fig. 5. I suppose, for very large enclosures, the rails could be welded up using steel angle material of suitable width and thickness.

Sloping Front Panel

By reducing the angle of one front notch and increasing the angle of the other, rails for a sloping front panel can be made. Caution! The rails will no longer be identical; you must make a right and a left rail. The dimensions and angle of notches can be determined mathematically, but it is simpler to draw out the side profile of the proposed rail and take the dimensions and angles from the drawing as shown in Fig. 6. Don't forget that now you must make the front panel larger than the back panel, to cover the longer sloped distance at the front.

Card Rack Enclosures

By using the fabricated rectangles as front and back rails instead of side rails and supporting them with side panels as in Fig. 7, an enclosure can be made with the top, bottom, front, and back accessible. By hinging the front and back panels, you have access to remove cards from the front and to service socket bus lines from the back of the enclosure. Piano hinges, which are available in different lengths, can be cut to size and are very sturdy. An enclosure for an S-100 bus system could be made up using a hinged top cover.

By now you can see the possibilities are virtually unlimited.

Cover It Up

A simple way to make a cover for the 3" x 6" x 8" enclosure described earlier would be to first make a bottom cover. Make sure this bottom plate is flush all the way around and fasten it to the rails with tapped or self-tapping screws pushed through rubber mounting feet. Or you can fasten the plate normally and use the self-stick feet that are available. *Note: If you make the front and back panels 1/16" higher than the 3" required, they can be offset down, when fastened, to cover the edges of the bottom plate when installed, to give a cleaner look.*

Bend up a clamshell to cover the top and sides as shown in Fig. 8. Don't be afraid of bending aluminum or light steel if you don't have a metal brake. A 4-foot length of 1-1/2" steel angle obtained at a junk yard, cut in half and held in a bench vise, works fine. A plastic-tipped hammer helps to sharpen the bends without denting the material. (A regular hammer and a wood block will do the same.) If you should want a semi-rounded look, the side rails can be rounded slightly with a file to soften the sharp edges. When bending wide surfaces with your homemade brake, use the vise in the middle and C-clamps at the ends to hold the angle pieces together. When making bends too deep for the vise, use an angled C-clamp at one end and the vise at the other.

If inadequate ventilation could be a problem, here is one approach. Drill holes in the bottom plate to let cool air enter. Make the clamshell cover about 1/8" or so higher than needed and fasten it up on the side rails so there is a gap between the top of the front and back panels and the cover. Warm air can escape through these gaps Make the cover 3/4" longer than the rails and overlap 1/4" at the rear and 1/2" at the front. The air gaps will not be noticed. Angle the edges of the cover at the front so it extends 1/2" at the top and is almost flush at the bottom. This gives it an attractive light-shield effect.

Concerning ventilation, if you have hesitated to drill holes in covers because you can't do it cleanly, read on. First determine the size hole and the spacing between holes which look attractive to you. Drilling out small scrap pieces of material on a trial basis might help you to decide. Carefully measure and draw out on the cover a grid of squares to locate the holes. Start from the center and work out so symmetry is retained. Use a center punch to make a

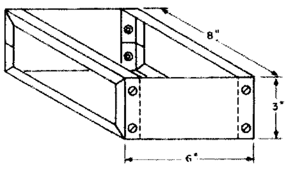

Fig. 4.

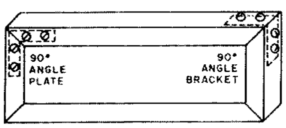

Fig. 5.

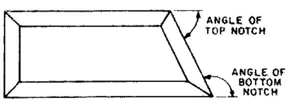

Fig. 6.

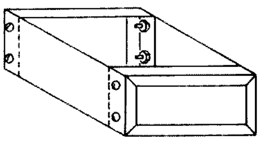

Fig. 7.

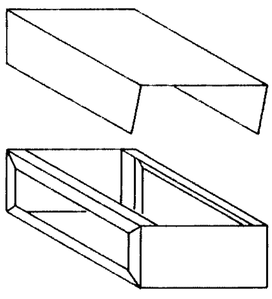

Fig. 8.

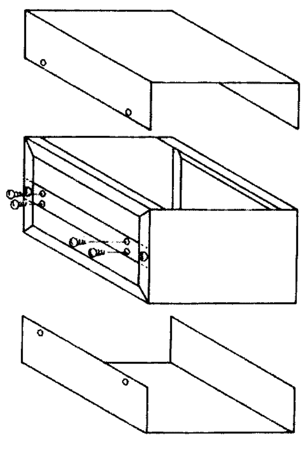

Fig. 9.

mark at the intersection of the squares of the grid. Use a small drill bit, 1/16" or so, to drill a pilot hole at each punch mark. The care with which you mark and drill the pilot holes determines the professional appearance of the end result.

Drill out the pilot holes with a drill the next size smaller than the drill you selected for the final hole size, then drill to final hole size. Keep this last drill handy. Sand down the burrs on the holes using the sturdiest sanding material you can find. The cloth-backed sanding belts from a small belt sander are perfect. Use a wood block to back up the sanding material. As the burrs are sanded down, push the drill bit through the holes to clean out the residue and sand some more. When the burrs are gone, use a finer grade of sanding material until the surface is smooth. Always use a backing block when sanding or the holes will be dished out. Keep pushing the drill through as you proceed to clean out the holes. You will end up with holes with perfectly clean edges, looking as though they were punched out.

A final word on covers: A double clamshell is a little more difficult to fit, but, as shown in Fig. 9, it may be more commercial looking. A piece of angle or strap material is fastened in the middle of the rail as shown and the two halves fastened to this when assembled. The popular bail-type handle also can be attached at the point of balance, if desired.

Dress It Up

Consider the use of a false front panel or escutcheon. When you mount the regular front plate to the side rails, use countersunk flat-head screws. If any other mountings or partitions are fastened to the front plate, countersink these also. A false-front panel will now cover up all the screw heads. This panel can be made of very thin material, painted attractively, or covered with one of the many self-stick vinyl products now available, such as wood grain. You may want to use the old trick of etching aluminum in a lye and water solution to produce a soft, satiny look. Use rub-on lettering for a professional appearance. If there are not enough switches or controls to hold the false front in place, use double sticky tape or dabs of silicone sealer (RTV).

If you are photographically inclined, you could draw up the panel, letter it, and photograph it. The lettering could be rub-on letters, carefully printed hand-lettering, or the product of a LeRoy lettering set or a Selectric typewriter. Make a print the proper size and fasten it to the false front with rubber cement. If your drawing is made on a black surface with white lettering, the print can be purposely underexposed to a medium grey and then toned to almost any color. (Ask at a photo store for toner of the color desired.) Spray lacquer applied to the print will keep it protected and looking new.

Several years ago I built my own electronic counter and used this type of enclosure. Since then I have made many changes and additions to the counter in order to keep up with the state of the art, and it has been a real pleasure to work on it. I can poke into it from all angles and add or remove boards at will. I can highly recommend that you try this method of enclosure construction for your next project.■

How Do You Use ICs?

—part XI

Battery power amps.

The article on linear preamps probably left a lot of battery-power freaks with their tongues hanging out. It bothered me, too. There was a nice simple way to get the preamps to work below nine volts with good margin, but only one power amplifier would go as low as nine volts—the LM380CN mini-DIP—and it was going to be critical at that.

There had to be a way; there's too much of a gap there. A little more digging in the linear book came up with a real humdinger.

I think you are going to like the LM386. It has a rated output of about 500 mW—which may not seem like much, considering what I said about the LM380CN. It, too, is in a mini-DIP package, but there are a few things that this one does that really make a difference. To start with, the IC works over a range of 4-12 volts. That takes care of your nine-volt battery just fine, and it can't be matched at all by the LM380CN or its big brother, and more than makes up for the slight output.

Even this should not be downgraded. The IC will handle a 4- to 16-Ohm speaker or set of phones, and, with phones, that 500 mW will pierce your ears for you.

There is, of course, one little drawback; there had to be. This is the maximum supply voltage. You can't exceed 15 volts source. This is rather close to the 13.8 volts on which your car or truck is supposed to run. It is possible that a surge might exceed that much, or some trouble might result in more voltage than the device can handle. It would appear a simple design problem, however, to include a zener to limit the voltage swing or a regulator circuit to handle it. This would be needed only for mobile use or where there was some possibility of voltage surges which could cause trouble. I don't see it as a serious problem if you take basic precautions.

Fig. 1 shows the device and its pinout.[1] This looks a whole heap like all the other amplifier ICs, but there are some differences.

Fig. 2 gives the hookup, another minimal-part circuit. There were a few subtle differences noticed with this IC compared with the others. The 0.05-uF cap and the 10-Ohm resistor do the same job as with the others. They suppress a high-frequency oscillation which may come. The output cap value is not critical. The larger value passes

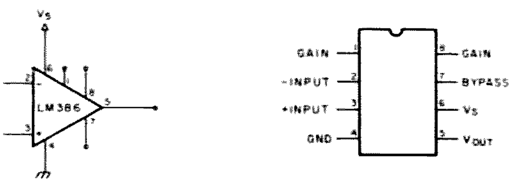

Fig. 1. LM386 low-voltage audio power amplifier.

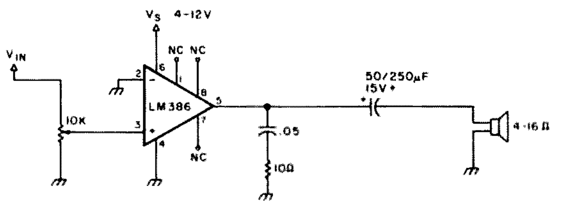

Fig. 2. Basic LM386 audio amplifier circuit.

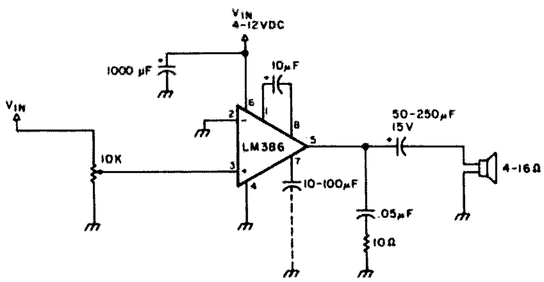

Fig. 3. LM386 high-gain circuit.

the low tones, and smaller value will cut them off, which is acceptable for communications use. The 10k volume control is not a critical value, but there should be something there, even a fixed value. With some configurations, there will be instability without an input resistor. The pin seven bypass may help in some applications, but I did not notice any gain in circuit performance with or without it.

Up to this point, we just about have a repeat of the LM380 series of amplifiers except for the voltage rating, but the LM386 has one more important trick up its sleeve. Notice that there are two pins labeled gain: pins one and eight. The circuit given here has a nominal gain of 20, which is about the same as the LM380 series. Using the gain pins can give you gain up to 200. The hookup is shown in Fig. 3. The 10-uF capacitor bypasses an internal resistor which limited the gain. With the 10 uF you get the full 200 or so gain. With a resistor in series, you can set the gain where you want it.

Fig. 4 shows that part of the circuit. The 1.2k value was shown in the application notes as giving a gain of about 50.[1] By ear, a 2200-Ohm resistor will give about the same gain as no RC network at all. The nearest variable you could use should be a 2.5k- or 5k-linear taper potentiometer. This would give you an adjustable gain option to play with. Remember that the pot gets hooked up backwards. To increase the gain, you decrease the resistance in the circuit.

Using this high-gain option has its price, too. That 1000-uF Vcc bypass is something new. I found that with this IC, a lot of supply bypassing is needed to avoid stray oscillation.

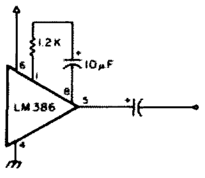

Fig. 4. 50-gain circuit.

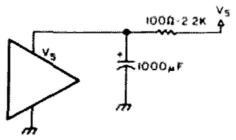

Fig. 5. Brute force bypassing for preamps or amps.

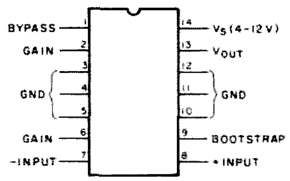

Fig. 6. LM388 1.5-Watt audio power amplifier.

This may be due to using the long power leads and test leads, but this is a high-gain IC. Even in the low-gain configuration, you may need this much supply bypassing as well as the input resistance.

Once the circuit is tame, the results are worth the effort; for sheer performance it is hard to beat. It combines in one package an effective audio-power amplifier with the sensitivity of the audio preamps. The circuit is simpler than the two separate stages would be and works just as well.

There was a bit too much measuring with the audio preamps, so this time let's stick to how it sounds. The power amplifier part actually sounds the same as the other power amplifiers, in its low-gain setup. It has a nice hefty output to your ear and should do any communications job easily. The sensitivity of the stage at low gain is about the same, too. This, by itself, is really quite sensitive. Using the mike, I was getting just about the same usable input to my ear as with the preamps and the high impedance phones of that test setup. When I went to the high-gain setup, things really got to be interesting. Once the circuit got tamed, it really took off in performance. That high-gain setup is *really* sensitive. I had no problem picking up background noise to my heart's content, but a nearby sound would scramble my brains. That thing is *loud*.

It has reinforced my feeling that there is little need for the separate preamp for most ham use. This one

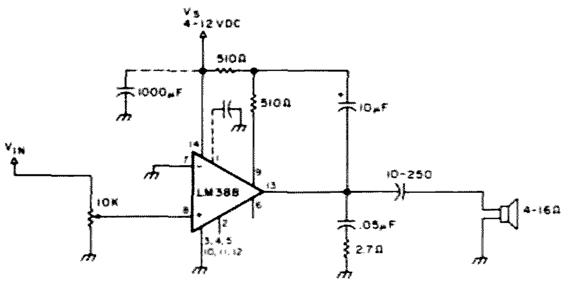

Fig. 7. LM388 basic circuit.

IC can perform the function—if needed at all—and much easier, by itself. It did bring up one serious hindsight view, however. When I did the preamp series, I used the bypass values on hand to tame the circuits. Beyond a certain point, they did not work. They were fairly low values reflecting what the application notes showed. At that time, I did not have any 1000-uF capacitors on hand. It may be that some of those high-gain stages which I found to be too unstable can be tamed with brute force bypassing.

Since the preamp current is slight, there is little chance of serious voltage drop, so you also can try *adding* a series resistor in the V_S lead shown in Fig. 5. A value of 1k or 2.2k might be a good starting point. This might tame some of those wilder circuits for serious use. I still don't think you will need all that gain, but if you do, it might be worth a try.

The LM386 appeared—by ear—to give the same functional sensitivity as the best of the preamp circuits given. They were in the 40-dB class. A gain of 200 is 46 dB.

There is one other IC in this family to watch for, the LM388, which is the big brother of the LM386. It is a 1.5-Watt, 14-pin IC power amplifier. (See Fig. 6.[2]) It is slightly more complicated to put together. The basic hookup is shown in Fig. 7. Notice the two 510-Ohm resistors and the 10-uF bypass. The high-frequency bypass circuit uses the values given also for the LM380—0.05 uF and 2.7 Ohms. Unfortunately, I was not able to get this IC from my dealers. I have never seen it or the LM386 listed, so you will have to write and see. The LM386 is available from James Electronics for $1.10.

Ordinarily I do not like to show a circuit without having tested it, but the power amps have worked so well that I think it is safe to do so. It gives you the basic information about it,

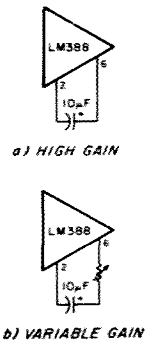

Fig. 8. LM388 gain control.

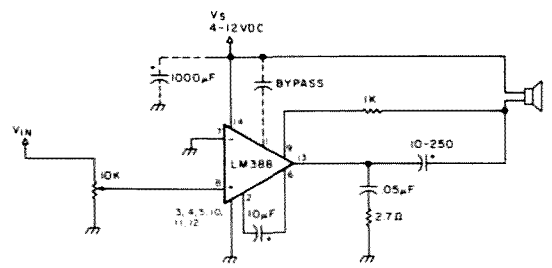

Fig. 9. LM388 load returned to V_S (gain 200).

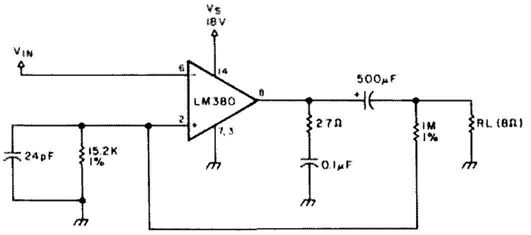

Fig. 10. LM380 high-gain circuit (not recommended!).

should they become available. The 510-Ohm resistors should be thought of as specific values in this case. They also are easily available from Jameco and other sources. The 10-uF value also is common.

This is the basic low-gain hookup—the same as the other, except for the power. I do not see a need for this for most purposes. If you are running on batteries, it means quite a bit more drain even at rest. This was a new IC, as of 1975 when my manual was printed, and there was little information included with it. I do not have the exact specs. It also has the high-gain configuration available with the addition of the capacitor between pins 2 and 6. There should be no reason why this should not be made variable as was the other. (See Fig. 8.)

There was one other circuit shown which was different from most presented. This was a high-gain circuit, but the load was returned to the V_S pin. (See Fig. 9.) I can't think of any reason why this should be a particularly desirable feature. It looks as if it might be possible for dc current to flow through the speaker winding, which might not be good for it. The manual did not say why this feature was included. My feeling would be to stay away from this circuit unless you know why you wanted it.

These ICs seem to be two-up on the LM380 series of amplifiers. They are low voltage and can be made higher gain. There is a way shown to turn the LM380 into a high-gain circuit. The specs say that, in theory, you can have gain up to 300, but they say this is hard to do and still keep it stable. The basic hookup is in Fig. 10.[3] Notice some extra parts in the basic LM380 circuit. The tip-off should be obvious. Those are one-percent resistors. I don't like one-percent resistors. Fortunately, I did not have any to try. I used a pair of resistance substitution boxes and clicked away. Very quickly, the circuit's capability showed up. For experimental use or breadboarding, it looks like a real bummer.

Without the extras, it is quite sensitive, but with them, the hum gets worse. I would assume it is the test leads. Even not counting the hum, however, the circuit didn't add anything. There was no noticeable increase in usable gain when tried with the mike input hookup. In fact, the sensitivity seemed to go down, and that's not counting the times it went into oscillation or just cut off. Even the addition of the big bypass capacitor did nothing to help.

Another bad feature of this circuit is that as you apply positive feedback to try to boost the gain, you also draw more current with the IC. This is not the healthiest thing for an IC to do. I don't think I permanently damaged any, but I wouldn't bet on it since some of them got hot to the touch. It is supposed to have built-in thermal shutdown, but why go asking for troubles like that? Stay away from this one.

I don't know why the circuit did not appear to work with any range of values tried, but that should be an indication that it is not suited to the reliable breadboard category that this series is based upon. Still, we have added one more reliable IC to the bag of solid-state tricks that are available: the LM386. It has its own strengths and weaknesses, but the battery-power option and the extra sensitivity if you need it make it a strong choice when you are planning a circuit.

Among all the linear ICs given so far, you should have something that will fit the requirements for almost any of the common audio amplifier uses. The tested circuits may not be the optimum achievable, but they should cut down on the amount of cut-and-try needed to get something that works for you. ■

Customize Your HT144B

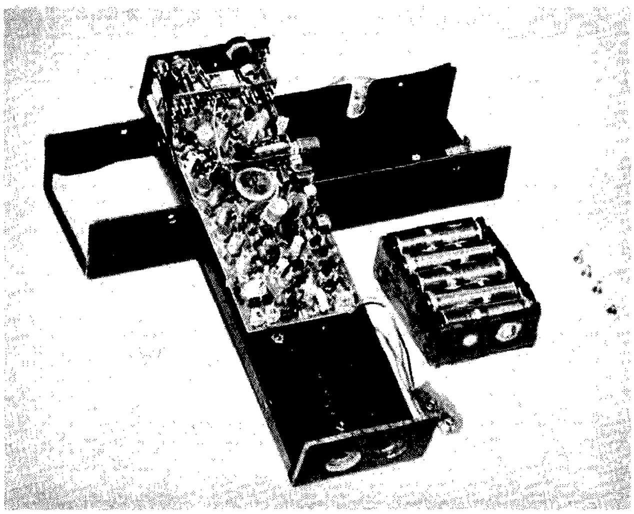
—some nifty mods

Total enjoyment of 2m.

L. Z. Sajor W2KGV
767 Lomas St.
Port St. Lucie FL 33452

Many hams have built the VHF Engineering 2 meter HT144B kit, which has proven itself an excellent handie-talkie. Here are modifications that will make it easier to service and use, therefore enlarging your total enjoyment of 2m FM. Described will be how to:

1. Modify for simplicity of crystal changing and repairs.
2. Add a "drop-in" battery charging facility.
3. Provide for an external microphone and earphone.
4. Replace the antenna with a rubber ducky.
5. Add a touchtone™ pad.



The HT144B open for inspection.

Difficulty in changing crystals is probably the only drawback of an otherwise well-designed handie-talkie, so I will start with that modification. First, disassemble your unit, removing the antenna, the printed circuit chassis, and the four standoff spacers, disconnecting any impeding wires as you go. File down the sides of two of the spacers, as shown in Fig. 1. Mount these two spacers, orienting the filed surface outward, directly to the PC board's top two holes, using lock washers and some nail polish as cement to hold the spacer securely. Mount the remaining spacers in the other two holes of the chassis in the same manner. Now, future removal of the chassis to change the crystals will only require removing the screws from the front of the case and sliding the chassis back, eliminating the twisting, clumsy maneuver previously required due to the interference of the threaded studs mounted on the side flange of the case front. Do not reassemble the unit as yet.

Now let's get to the "drop-in" battery charging feature. First, determine if you have at least a 3/16-inch space between the bottom inside of the HT and your battery pack. If not, then obtain a battery carrier that will allow you the space. Disassemble those parts of your unit still remaining that would interfere with unobstruct-

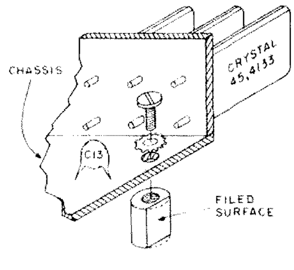


Fig. 1. How mounting studs are filed and oriented.

ed drilling of the case. Drill or punch out two ¾-inch holes as shown in Fig. 2. Next, fashion a piece of 1/16-inch-thick insulating material to fit the entire bottom inside of the case. Place it in the bottom and scribe thereon the location and outline of the holes you just made. Drill a 3/8-inch hole in the center of each scribed area. Secure this piece in place with cement or thin double-faced adhesive.

Next, we modify the battery holder. For this, you can etch a piece of one-sided copperclad PC board in the pattern and dimensions of Fig. 3 or cut out the design from thin copper sheeting.

Now, lightly "flow-tin" some solder onto the copper to provide better corrosion resistance (silver plating would be nice, if you have the facility). Affix the PC board or strips to the battery holder with cement or double-faced adhesive (to the side nearest to the snap connectors). Solder wire leads from the strips to the connectors, using care not to defeat the snap action and, more so, not to melt the plastic of the battery holder. Since this plastic melts easily, a dish of cold water for dunking immediately after soldering is a helpful precaution.

You should now have a snug-fitting battery pack when the HT is reassem-

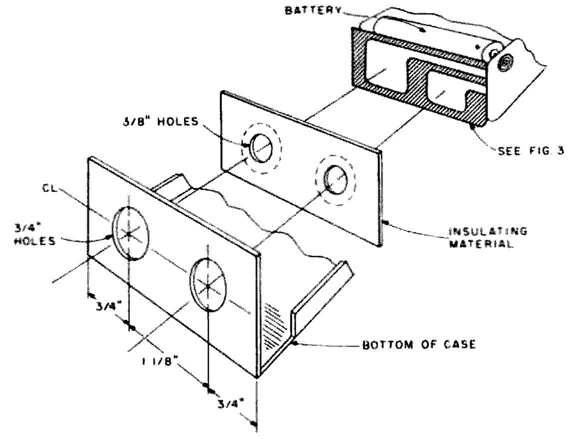

Fig. 2. "Drop-in" battery charging assembly detail.

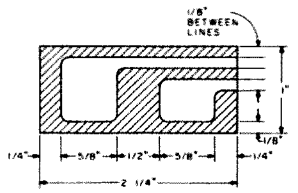

Fig. 3. Battery charging contact strip.

bled. If not, a simple cardboard shim between the battery pack and the circuit board is called for. Looking at the bottom of the HT, you should be able to see the contact strip material through the holes on the insulating board, which will be insulating them from the case by a circular area at least 1/8 of an inch wide. Paint the positive contact insulated area with red nail polish for identification.

Since it will no longer be needed, the charging socket at the top of the HT is removed and the holes used for the external mike and earphone jacks and, as a bonus, for a small LED to indicate a power-"on" condition (see Fig. 4 for layout). The LED is especially valuable, as the switch on the volume control can easily come on without enough audio being present to warn you that the battery is draining. The LED drain is minimal. Solder a "U"-shaped piece of solid #22 wire to the cathode of the LED and a 330-Ohm resistor to the anode (see Fig. 4 for configuration). Solder the other end of the "U"-shaped wire to the metal frame of the channel switch in a position that will allow the LED to slide easily into the hole left by the battery charging jack holding screw. Now, route the resistor up over and down toward the on/off switch and solder it to the proper contact so that, when the switch goes on, the LED will light.

At this point, install the microphone and earphone jacks, using closed-circuit types. Use a miniature phone jack for the microphone and a subminiature one for the earphone. Use shielded wire for the connections, as shown in Fig. 5. Wiring it in the manner shown will enable you to use the internal speaker-mike as usual, but have the convenience of using an external microphone-earphone assembly if you wish (see photo).

The Rubber Ducky

The installation of the rubber ducky is simplicity itself. Most easily obtainable and priced right is the Radio Shack #20-178 VHF. If you opt for this antenna, you can use either a subminiature phone jack or an old-fashioned pin jack. Be sure that the center contact of the jack is insulated from the case. Use shoulder washers if necessary.

Now, dig into your junk box for an old 7- or 9-pin tube socket and cannibalize it for one of the pins. It should be one that will serve as a single-pin socket for a number 16 or 18 solid, tinned copper wire. This pin is then soldered to the proper contact of the antenna jack. A 2-inch length of the solid wire mentioned above is now inserted into the pin. Slide a piece of insulating tubing about 1¼ inches long over the wire. The wire is routed straight down to the push-to-talk switch and then at right angles to the switch's

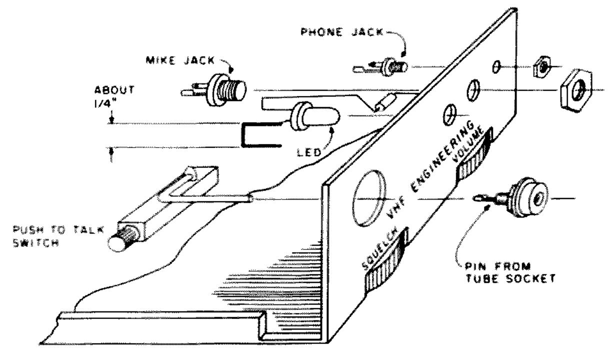

Fig. 4. Antenna and microphone plus speaker jack assembly detail.

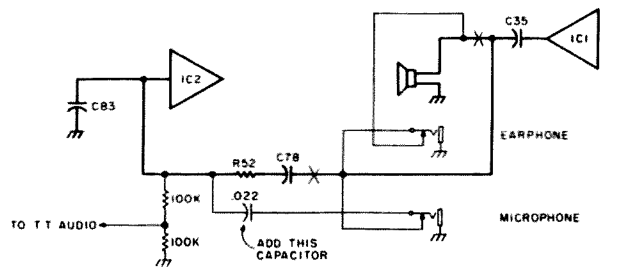

Fig. 5. Original circuit of HT 144B is in heavy lines; the modification is in light lines.

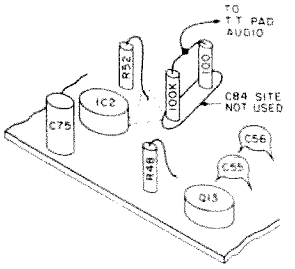

Fig. 6. Touchtone connection point showing resistor network positioning in C84 position.

antenna change-over contact. Solder it to the contact. This lead dress is important to prevent feedback. You now can avoid the chore of unsoldering the antenna connection every time the chassis is removed for crystal changes or repairs. See Fig. 4 for details.

The Touchtone Connection

By using one of the slim touchtone pads, such as one made by Barber Corp., the pad can be mounted on the outside of the HT without really adding to the bulk. If you cement the pad to the HT, you then need only one hole for the wires. Alternately, you can bolt it to the HT using small screws, but be careful that they do not intrude upon the space available for the battery carrier. The audio from the pad will need to be attenuated by a resistor network of 100 and 100k Ohms. There is a tailor-made place for the network on the chassis in the place left vacant by the unused capacitor, C84 (see Figs. 5 and 6 for circuit and layout).

Final Touches

Before buttoning up your HT, make the hole used for the push-to-talk button into a slot by cutting away the material between the hole and the edge. A nibbler does this more neatly than a hacksaw. In either case, smooth the edges, round them off slightly, and touch up the bright aluminum with flat black paint. You will now be able to remove the cover of the HT without needing to remove the push-button, which often becomes loose from frequent removals (see Fig. 4).

As a final touch and to give a nicer feel to the HT, I applied an imitation leather material to the back of it. I did not slot the push-to-talk button hole in the material, but punched out the hole and cut a slit from the edge to the hole. The stiffness of most materials will yield enough to permit passage of the button on removal or installation and yet maintain a closure at other times to give a neat appearance.

With the foregoing features installed on my HT, I use it in comfort every evening on the commuter train by holding the HT on the windowsill. With the external Plantronics headset which requires very low voice levels, there is no disturbance to fellow passengers, but it does generate a great deal of interest among them. During the several transit delays due to weather, fire, and accidents, it was comforting and useful to have the HT to advise the XYL of my homeward progress or lack of it. Autopatch or the good offices of fellow hams on the repeaters in the area provided the link. In fact, the XYL monitors the repeater for the 20 minutes prior to our usual arrival time, and, by dropping the right cue words in our QSOs, such as "This is W2KGV mobile 2 on the ConRail at White Plains station," she knows when to leave for my station to pick me up. Very convenient. ■

Ultra-Simple CMOS Logic Probe

—a single IC does it all

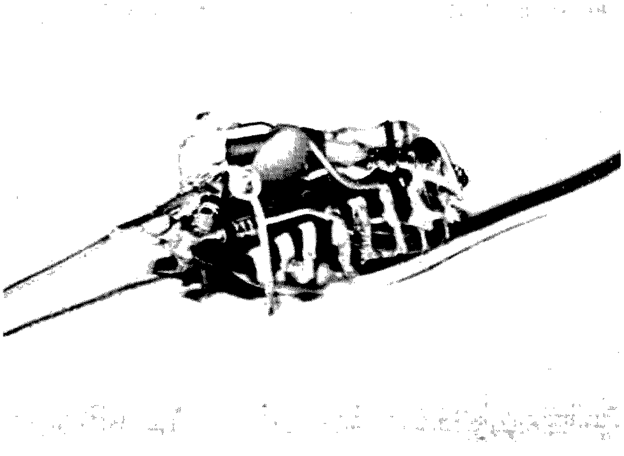
Make sure your troubleshooting is on target.

When it comes to troubleshooting digital IC projects, a logic probe is indispensable, and, with so many construction projects employing digital technology, almost anyone can use one. Most commercial probes represent two problems in the eyes of hams and hobbyists: Commercial probes cost from $25 upward; and a given probe generally works with only one type of logic (TTL or CMOS). This article describes a design for a logic probe which meets all requirements for troubleshooting digital circuits, and solves the two problems mentioned.

The circuit shown in the schematic (Fig. 1) is fairly simple. The gates are CMOS, which has several advantages in this application:

1. CMOS gates have a very high input impedance and will not load the circuit being observed.
2. CMOS may be powered from 3 through 15 volts, so that the probe may be used in both CMOS and TTL circuits.
3. The supply current for CMOS ICs is extremely small, so the probe may be powered parasitically from the circuit under test—even from low-powered battery circuits.
4. CMOS gates are easily made into "one-shots" (which lengthen out pulses to make them visible).
5. CMOS has self-limiting current sourcing and sinking, which allows LEDs to be driven without the use of series resistors.

The circuit is built using five inverters, a NOR gate, a resistor, three capacitors, and three LEDs. This configuration brings another advantage. Motorola has



This is a closer view of the probe showing the method of using the IC as the component base. The capacitor lead is used for the probe tip.

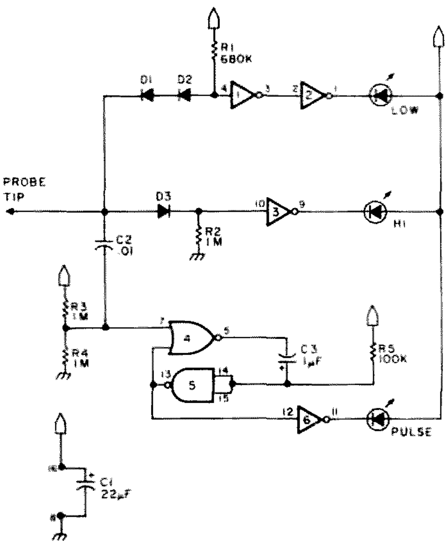


Fig. 1. Single IC logic probe.

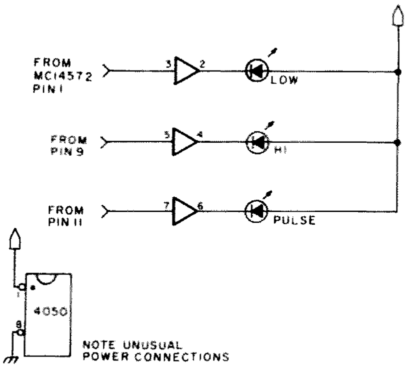

Fig. 2. Using a 4050 for extra drive.

produced a CMOS package, appropriately called a HEX gate, which contains 4 inverters, a NAND gate, and a NOR gate, which sells for about 50¢.[1]

Operation

The operation of the circuit is as simple as the circuit itself. If the probe tip is touched to an active high (or "1") signal, inverter 3 turns on the high LED, while inverters 1 and 2 keep the low LED off. When a low (logical "0") is identified by the probe tip, inverters 1 and 2 cause the low LED to turn on, and inverter 3 keeps the high LED off. The two inverters on the low line are there for buffering purposes.

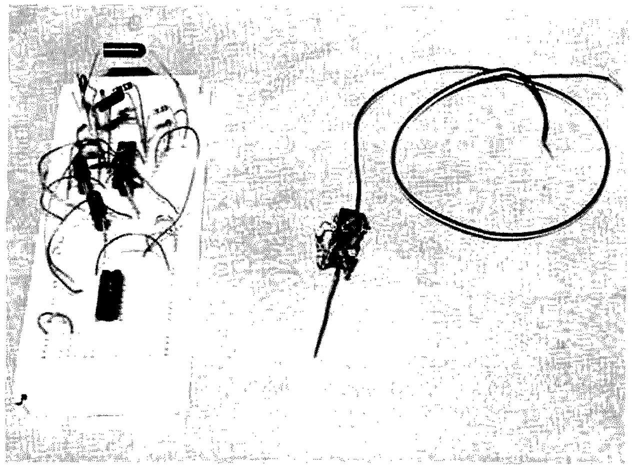
When idle, the 1 meg resistors split the supply voltage, letting R5 pull the output to a high state. This charges up the capacitor, C3, which then applies a high to the NAND (being used as an inverter), which holds the inputs to the NOR and inverter 6 low. When a negative edge of a pulse occurs, it is slowed up by the R1-C2 time constant (since the capacitor voltage cannot change instantaneously). This lengthened pulse changes the NOR output to high. Again, the pulse is lengthened by the time constant of C3 and the pull-up resistor, R5. The input to the NAND slowly changes (compared to the input pulse!) from high to low. The gate characteristics cause more of a "snap-action" than the rise and fall of the capacitor voltage. This is further squared off by inverter 6. The high signal is fed back to the NOR, which brings the output low again. (This is the "one-shot" effect.) When inverter 6 receives the lengthened pulse, it illuminates the pulse LED for the duration of the pulse.

CMOS can exhibit some memory action when the input is removed from a signal source and left floating. The diodes and pull-up and pull-down resistors eliminate this memory problem to ensure normal operation of the probe. The resistor values are fairly critical. With the values shown, the probe operates well from 0-9 volts. At more than 9 volts, some leakage current will cause the high LED to light dimly. This is easily distinguishable from a true high, however, and it will go out on a low.

Construction

If it is desired, a printed circuit board can be made. However, the author and several other builders found it easier to trim leads short and either solder or wire-wrap directly to the IC. This provides an extremely compact circuit.

The probe, when built as described above, can be mounted in about anything that is convenient.

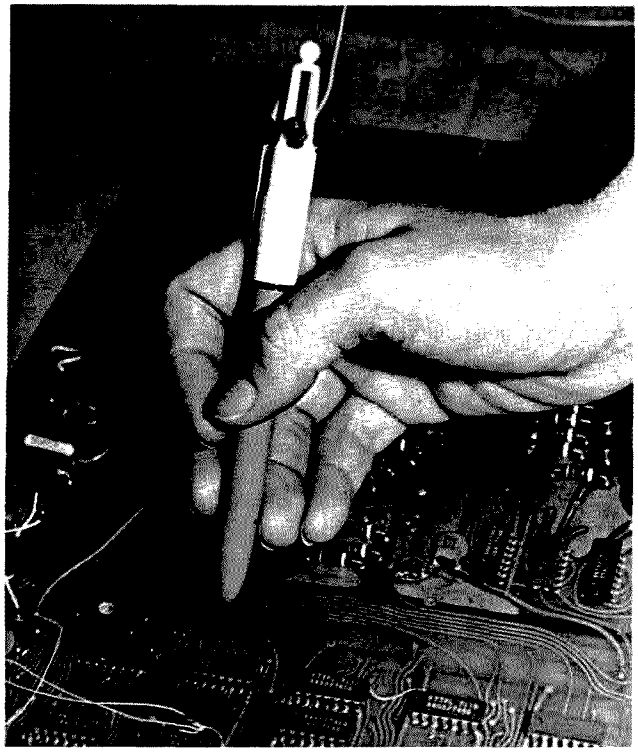


Here are two different prototypes. All the components in the left-hand version are in the right-hand version, except for the 4050 at the bottom of the protoboard. Also, smaller LEDs were used.

My model was mounted in the casing of a Bic 4-color pen. This provides extreme portability, with the pocket clip allowing the probe to be carried around.

If desired, the LED outputs could be used to produce high and low tones, using 555s for an audio logic probe.

I have two final construction notes. The 22-uF



This is the final assembled version. A Bic 4-color pen was used as the case. The LEDs and power leads can be seen at the top, and the tip is probing an IC at the bottom. Practically anything can be used as a case, such as a cigar tube or cylindrical plastic mailing tube. You could even leave it in the "rodent" form!

Parts List

IC 1	Motorola MC 14572 CMOS integrated circuit
D1-D3	Small signal diodes, 1N914 or similar
R1	680k, ¼-Watt
R2-R4	1 meg ¼-Watt
R5	100k ¼-Watt
C1	2.2 uF tantalum (see text)
C2	.01 uF ceramic disc
C3	1 uF tantalum
LED1-LED3	miniature LEDs—color reader's choice
Optional	
IC 2	4050 CMOS hex buffer (non-inverting)

tantalum capacitor between Vcc and ground is to provide additional filtering. This value is not too critical, and the circuit may work on a good power supply without it. Also, while the LEDs are not too bright, they are sufficiently bright for normal work. For a few cents more and an additional IC package, a 4050 CMOS hex buffer can be used, if desired, to provide added drive, as shown in Fig. 2. For ultra-simplicity and small size, however, the single IC version is recommended.

Conclusion

While a logic probe may be the most useful tool in a ham shack, commercial models can be fairly expensive. This probe can be built even on a poor man's budget, and, for anyone working with digital circuitry, a cheap logic probe is practically a must. ■

"The Voice of Wolf Creek"

—the KGCX story

How to operate a radio station without a license.

Dr. William C. Hess W6CK
PO Box 19M
Pasadena CA 91102

Beginning in 1924, the late Joe Jacobs 7TF operated an unlicensed broadcasting station on his ranch in the wilds of Montana. In late 1925, this station was moved to the tiny village of Vida, Montana, where its illegal operation was continued by the local banker, E. E. Krebsbach. The following transcript of a 1930 speech given by Krebsbach to the Lions Club of nearby Wolf Point, was recently presented by the Krebsbach family to their long-time friend, Dr. Hess, because of his abiding interest in the history of KGCX. It details the trials and tribulations involved in operating this clandestine radio station until it was licensed and the services of a licensed operator were secured.—Ed.

Five years ago, in 1925, when I returned to Wolf Point after undergoing surgery at the Mayo Clinic, some of the local radio enthusiasts told me of hearing "The Voice of Cow Creek" on their radios. Of course, I knew at once that it must be the work of Joe Jacobs, eastern Montana's radio wizard. And it was.

At that time, Joe had a license only for operating an *amateur* station, but he was going on the air with musical programs on a wavelength of over 200 meters, which was strictly forbidden by the Department of Commerce.

Being interested in seeing a real broadcasting station which could transmit voices and music, I went down to the Jacobs Ranch as soon as the condition of the roads permitted. Joe had the transmitter sitting on a small table, and while it was not the neatest piece of construction I have ever seen, it did the work that any transmitter is capable of doing, and it did mighty well, as you all remember.

Instead of using high-priced meters such as we are using now, which cost anywhere from twelve to twenty-five dollars each, he was using old discarded seventy-five cent voltmeters. The panel was only two-feet square.

He had a hand-held microphone which had to be carried around the room to pick up organ music, phonograph, or whatever type of music they could get at their ranch home. The microphone had to be held up to the organ frame so the vibrations could be picked up; the same was the case with the phonograph music. The mike had to be attached to the phonograph cabinet, otherwise the volume of pickup would not be sufficient for broadcasts.

We all got a great deal of pleasure out of it, and I suggested that I bring the Vida Syncopators Orchestra down to the ranch and broadcast our music. Mr. Jacobs suggested that the set be taken to Vida instead, as we had more room there to broadcast from the Community Hall.

So, it was not long before Vida had a direct connection with the outside world—a pure and simple bootleg, wildcatting radio station. We operated Sunday afternoons only, and from the number of letters we received, we had a great many listeners to the foolishness we put out. I believe that at first we tried to make ourselves as foolish as possible.

In a very short time, Mr. Jacobs perfected what is known as the electrical phonograph pickup. Whether it was an innovation on his part, I don't know (he used a headphone to make it), but I do know that it was the very first time phonograph music was broadcast in the entire middlewest by the now-common electrical pickup process. Other stations at that time were broadcasting phonograph music by the now entirely obsolete system of merely placing the microphone in front of their phonographs. With that system, the quality, of course, was not nearly as good as with the electrical pickup process. It was at least a year before other stations started using our

system. This is one thing in the broadcasting game in which we were absolutely the pioneers.

We became so interested in the novelty of broadcasting that we applied to the Department of Commerce for a broadcast license for Vida—a town of twenty-five inhabitants. Of course, we assumed they would forget to look up the population of the fair city. We received a reply stating that a ban had been placed on all further radio station construction, and that the number of radio stations was to be reduced, not increased.

Still, we kept on broadcasting, not knowing the penalty. The penalty for operating a radio station without a license was $500 and six months in the coop. We did not know this, but *did* know that the practice was not exactly according to Hoyle.

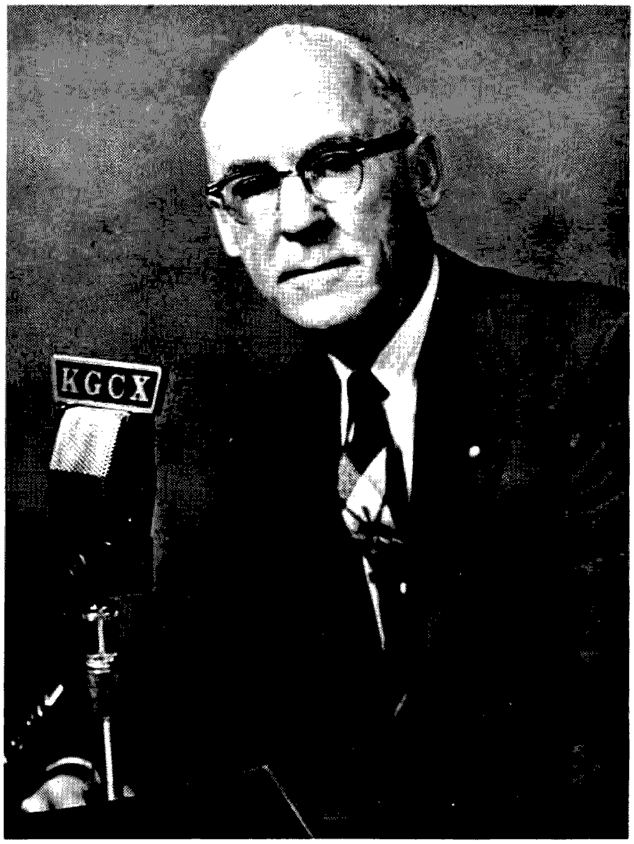
This shows Mr. Krebsbach operating the original KGCX transmitter at Vida, Montana, in 1926. Note the crank of a hand-wound phonograph at the left edge of the picture.

We started reaching out quite a distance with our broadcasts, and, finally, a bit too far, as we were heard at Froid, Montana. A certain gentleman there (this is not the term we applied to him at that time), who did not approve of Vida having a radio station when Froid could not have one, immediately sent in a complaint to the radio inspector at Seattle stating that an illegal broadcasting station was operating at Vida under the name of "The Voice of Wolf Creek."

We had changed the title of the station to this appelation when we moved it to Vida, since Vida was near Wolf Creek. Naturally, the radio inspector knew who to write to at Vida since we had submitted our application for a broadcast station to him. We knew that the applicant for a station had to be a reliable person or firm, so we had used the name of the bank where I was the cashier. So, the inspector wrote a letter at once to the First State Bank at Vida, asking the name of the owner and operator of the station at Vida—not licensed by the government—so that he could commence prosecution at once.

All was not so good around Vida (especially in the bank) for a week or two! Paul (my brother) would come in every now and then, saying, "I told you so" and "now don't get me into it"—all nice, cheery remarks, you know. The final outcome was that Mr. Jacobs lost his amateur license, and nothing further was done.

I asked a number of my friends in the surrounding towns to write to the inspector telling him that Joe was brokenhearted and felt terrible over the abrupt ending of his chosen career. About two weeks later, Joe received a letter from the Department of Commerce asking whether he wished to be reinstated



This is a picture of Mr. Krebsbach in the 1950s, at the KGCX microphone.

—and Joe was soon restored to the status of being a full-fledged amateur operator, *but* he refused to have any further connection with the bootleg radio station.

Naturally, we thought that that was the end of our broadcasting career, as we surely now had a black mark with the Department of Commerce about a foot wide. In the meantime, I got in touch with Mr. Willson of the Fobes Radio Supply, at Butte. Mr. Willson happened to be a close friend of Mr. Redfern, who was the supervisor of this 7th Radio District. I don't know what Mr. Willson did, but I do know that he was instrumental in getting our first license with the call letters KGCX. We started unlicensed broadcasting at Vida on October 1, 1925, and received our license at Vida on October 6, 1926.

At first, we started on a one-day schedule per week, broadcasting only on Sunday afternoons, as we had done without a license. However, now that we were a legitimate station, we increased the broadcasting schedule to Monday, Wednesday, and Saturday during the noon hour, and very shortly went on a daily schedule from 12:15 to 1:15 pm.

To show you how much nerve we had (that is not the exact word, but will do), we did not have a resident licensed operator as required by the government. Since we badly needed someone with a First Class radio operator's license, we decided to go to Butte on the day the assistant radio inspector was scheduled to be there giving radio examinations, so that Joe could take the First Class operator's exam.

On the designated morning, we walked over from our hotel to the Post Office building where the examination was to be held. Joe sat down, waiting for the test to start, and I went back to our hotel, about as nervous as I have been here with this station at times. I phoned Mr. Willson and told him Joe had started the examination. "Well," he said, "if he is not back at the hotel in an hour, he will have passed his code test, and then everything will be hotsy totsy."

I sat in the lobby of the hotel with my back to the door and watched the clock. For the first fifteen minutes, I was slightly nervous, and before the hour had expired, I was a nervous wreck. Each time the door to the lobby opened, I would think it was Joe coming back. The hour passed and Joe did not come; another hour passed and finally it was lunch time. I asked Mr. Willson to lunch, and we both went up to see Joe. He said he had failed the first two code tests, but that Mr. Clark, the examiner, was very nice to him and allowed him a third try at the code test, which he passed.

I thought that that was all there was to it, as surely Joe could not fail the technical part of the examination. In those examinations, you are required to know the construction of a ship transmitter, a land transmitter, and the construction and maintenance of storage batteries. You must be able to draw a complete diagram of a transmitter, and you must know ten of the radio laws. You must know what the source of the trouble is when a milliammeter, voltmeter, radio-frequency ammeter, or other meters fail to respond. And this is about half of the work in the examination, which ordinarily takes a full day to complete.

Joe finished his examination at 3 o'clock, and we went to a movie to relieve the strain. We were both happy, to say the least. We had finally conquered!

We stopped at a nearby drugstore, and phoned the radio inspector and asked for results. Joe had *flunked* by a mere three points. It was just a small matter of forgetting to connect the motor generator to the transmitter, in the diagram which Joe had drawn.

Right there and then, all of the joy went out of our lives completely. We were homesick, sick at heart, and what not. We went back to our hotel room, and Joe paced the floor on one side of the room and I on the other side. We phoned Mr. Willson and he asked us to come down to his office, which we did, and he asked us out to his home for dinner. On the way out, I remarked with a good-sized lump in my throat, "Well, that's the end of KGCX."

Mr. Willson said, "Why?"

"Well," I said, "I can't operate the station any longer without a licensed operator and risk being caught—I'll be fined $500 and spend six months in the hoosegow."

He said the $500 fine and six months in jail did not apply to operating a station without having a licensed operator, but rather to operating a station without a license.

He also said that the penalty for operating without a licensed operator was merely revocation of the station license, and that if you quit broadcasting now, you will have to surrender your KGCX station license, and then you will be through as far as getting another station license at Vida is concerned.

He further said that if you continue broadcasting without a licensed operator and get caught, the worst that can happen is that your station license will be revoked, and even if that happens you won't be any worse off than if you quit now.

He continued, "but if you continue broadcasting, Joe can take the operator's examination again in three months and will surely pass then."

Right at this point is where Wolf Point nearly never would have had a broadcasting station as, if we had followed our dictates and stopped broadcasting then at Vida, Wolf Point would not have a radio station today. The much-coveted license would have been gone forever.

We returned to Wolf Point, and it was pitiful to see Joe so nervous and disappointed over his failure. I should say at this point, that there is absolutely no disgrace in one's inability to pass the First Class operator's examination on the first attempt. I know that I would not attempt to take it at this time.

We continued to operate the Vida station, and everything went smoothly until the following June when we received word on a Friday evening that the radio inspector would arrive at Wolf Point on the following Monday morning to inspect KGCX at Vida.

The first thing to do was to hotfoot it to Wolf Point and get in touch with Mr. Johnson, at Havre, who was the holder of a First Class operator's license. He agreed to come to Wolf Point on the Sunday morning train, but he did not show up. I wired him, and he phoned back advising that he had missed the train, but that he would come on Number 4, that evening, for sure.

He did, and we spent all night rehearsing the manner of operation of our transmitter, its construction, our broadcasting schedules, etc., so that he would be fully informed and be able to deceive the radio inspector into think-

ing that he, Johnson, was actually the licensed operator of KGCX. Actually, Johnson had only been at Vida on one other occasion, when he visited there briefly just to satisfy his curiosity about our transmitter. As you know, there was only one other radio station in the whole state of Montana at that time, besides ours.

Next morning, Mr. Clark, the assistant radio inspector, was to arrive from Seattle. I had arranged that Mr. Johnson would be taken to Vida that morning on the first ferry crossing over the Missouri River. I had also arranged to have Joe Jacobs on hand early in the morning at Vida, so that he could give Johnson a final "brush-up" on our transmitter, so that we would be sure to deceive Mr. Clark about Johnson being our licensed operator.

Naturally, Johnson knew very little about our transmitter, having seen it only once before. My brother, Paul, was in a terrible sweat, and later told me this was quite sufficient for him, and that he did not want to be "in" on any radio station venture of mine, ever.

Mr. Clark arrived on Number 2, Monday morning as scheduled, and I stalled around Wolf Point as long as I could in order to give Joe as much time as possible to "clue in" Johnson about our station at Vida.

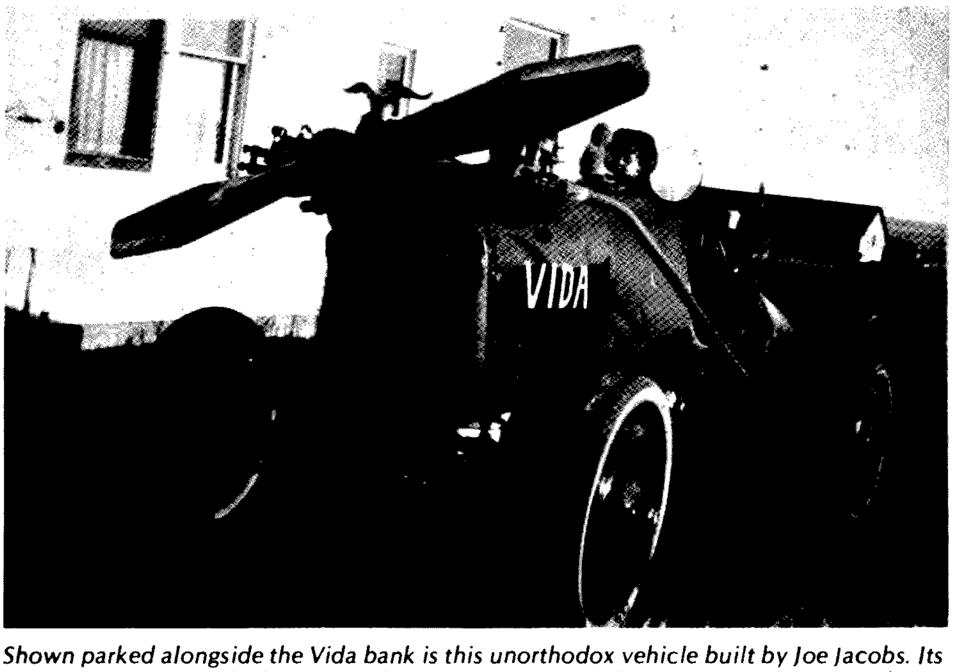
During the trip to Vida, I was preparing Mr. Clark for the shock he might get when he first viewed our transmitter at Vida, as it was just a cheaply assembled set. To all this, he said, "Well, don't worry about how the set looks as long as your broadcasts go out all right."

When we reached Vida, Joe Jacobs was sitting leisurely on the front steps of the bank, apparently unconcerned about the approaching dignitary from Seattle.

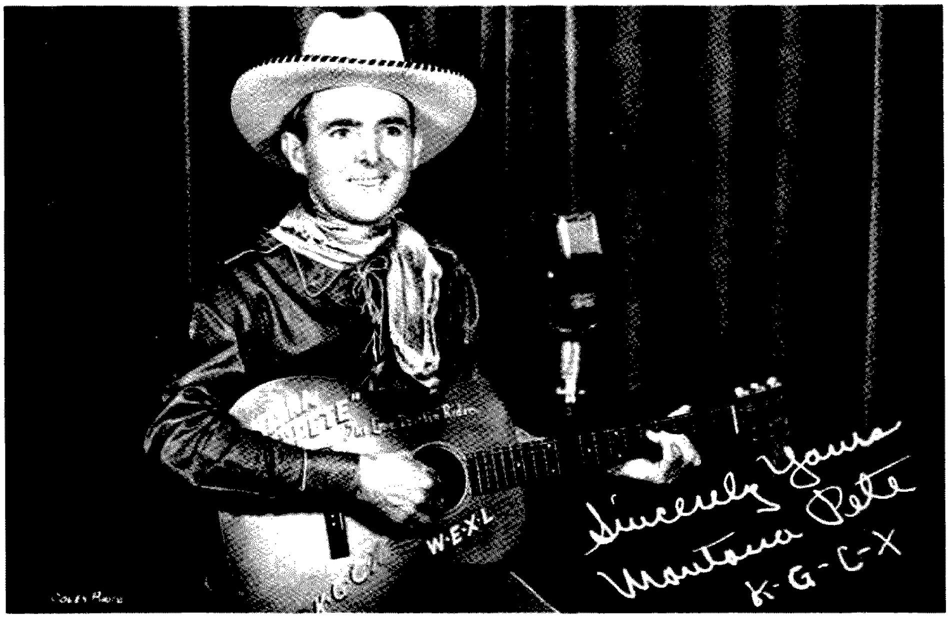
In the event that the radio inspector might happen to go into the village general store and Post Office, for any reason, and to help give the impression that Johnson was indeed a resident of Vida, who worked at the store when he was not on duty as the licensed operator of KGCX, a bit of flummery was arranged. So, when we arrived at Vida, Johnson was already in back of the counter at the store with his coat off, busily selling butter and eggs, and posing as a clerk in a store which he had just entered for the first time in his life. Obviously, the storekeeper was a part of the conspiracy to deceive the Department of Commerce, since he wanted Vida to be able to keep the radio station, as did everyone in the surrounding community.

Joe stepped into the bank with Mr. Clark and started his First Class operator's examination. I went over to the store and asked Johnson to come over to the bank. During Joe's examination, Mr. Clark inspected everything about our transmitter, the antenna system, etc., and asked Johnson to turn on the transmitter and transmit a phonograph record. This came through nicely, and the inspector then asked for an announcement through the micro-

Marcellus Jacobs poses to give prospective customers an indication of the size of the Jacobs wind electric plant.



Shown parked alongside the Vida bank is this unorthodox vehicle built by Joe Jacobs. Its airplane motor would whiz it over the prairies at 40 mph. In winter, it was equipped with skis. Note the antenna insulators and ground system of KGCX at the left. Seated in the vehicle is young Clair Krebsbach, now General Manager of 50-kW KERR.



Montana Pete performed for years on KGCX. When he departed for greener pastures, KGCX held a farewell party for him in the form of a barn dance, with live coverage of the affair provided by the station. Mr. Krebsbach, acting as master of ceremonies, intended to say into the mike, "We shall certainly miss Pete." Unfortunately, he transposed the first letters of the last two words. His profuse apologies to the hundreds of KGCX listeners, and to those present at the party, only made the situation worse.

phone. Johnson talked into the mike, but the inspector, who was listening on a radio in another room, said nothing came through. We were then using a desk-stand telephone as a microphone. Jacobs looked up from his exam papers and saw the telephone receiver hanging on the hook (which short-circuited the mike), and quietly told Johnson to take the receiver off the hook, which brought a faint smile to the face of Mr. Clark.

At dinner that evening in our living quarters in the bank, with Mr. Clark as a dinner guest, my young son had to help things along by telling his mother, "*Mama, Mr. Johnson is here again, isn't he?*"

It may be that Mr. Clark sensed that something was, indeed, amiss, but he said nothing. In any event, he was very nice to us, and Joe had passed his examination and all was well.

I was startled again at the ferry when we were returning to Wolf Point. Johnson, of course, had to return to Havre. Mr. Clark was going east. As I was starting home, Mr. Clark bid me goodbye *and on came Johnson to also bid me goodbye.* Rather strange for my operator to bid me goodbye.

I am sure that because of the remark my young son had made, and because Johnson bid me goodbye, there was little doubt in the mind of Mr. Clark that I had been operating KGCX without the services of a licensed operator. However, he said nothing.

We operated KGCX at Vida until February 1, 1929. At that time, I took over the Westland Oil Company agency at Wolf Point. I thought it would be very nice if we could continue operating a radio station in this area, so I applied to the Federal Radio Commission for permission to transfer the Vida station to Wolf Point. They replied that they would approve the transfer, but that they would not allow us to use the small 7½-Watt transmitter we had used at Vida. They told us we must use either 100 Watts or 250 Watts up to sunset, and 100 Watts after sunset. We first planned on 100 Watts, but Mr. Hooper, of Regina, informed us that a 250-Watt set would cost but little more, so we made application for that power.

We had no knowledge whatsoever as to what information we should put in the application relative to the rating of the tubes, the type of transmitter, and other such items, and this necessitated a trip to Regina to get the required information from Mr. Hooper, who was chief engineer of radio station CKCK, up there in Regina, Canada, about 175 miles north of Wolf Point. We made the trip via airplane, as the roads were impassible, and after going through some hair-raising experiences on the trip (two forced landings with a dead motor), we brought the necessary information back to Wolf Point and submitted our application to the Government.

We thought that we would have our construction permit in two or three weeks, but six weeks went by with no word from the Commission. I telegraphed Senator Walsh and Congressman Leavitt, in Washington, and within twelve hours I had a telegram from Mr. Leavitt advising me that the permit had just been granted and that we were assured a 250-Watt station in Wolf Point. ■

Author's note: The foregoing speech was never given a title by Mr. Krebsbach. It occurs to me that the name of a popular magazine would be an apt and accurate title for the subject speech, viz: *True Confessions.*

The village of Oberammergau, in Germany, is famous for its Passion Play, and the town of Hemet is well known in California for its annual outdoor Ramona Pageant, but for sheer audacity and raw courage on the part of its actors, the tableau just described, which was presented at Vida by Mr. Krebsbach, First Class Operator Johnson, the village storekeeper, et al, in attempting to deceive the Department of Commerce of the United States government, has no equal.

Joe Jacobs and his brother, Marcellus, did a great deal of experimenting with wind chargers on their ranch. Later, they established a large factory in Minneapolis and were able, through their 260 dealers, to sell twenty million dollars worth of wind chargers to farmers, airports and railroads throughout the world, an impressive accomplishment all stemming from the electrical tinkering of two young men on a Montana ranch.

Joe Jacobs passed away in 1962. In 1933, Marcellus invented the cathodic pipeline device which has saved pipeline companies millions of dollars. He still carries on electrical experiments in a large laboratory near Fort Myers, Florida, where another electrical tinkerer, Thomas A. Edison, developed many of his patents.

CB to 10

—part XIX: Lafayette SSB rigs

They work like champs.

Fred H. Gerken WB0LLP/5
7009 Knight
Lewisville TX 75056

Recently, due to the extinction of 23-channel CB radios, several amateurs have converted SSB CB rigs to ten meters with great success. The fun of QRP operating, and the band openings lately, have contributed to their present popularity. The following information is a basic description of how to convert two of Lafayette's 23-channel SSB radios to ten.

The first step in any conversion is to decide on a frequency scheme. Since most SSB activity on ten seems to be around 28.6 MHz, and since the phone

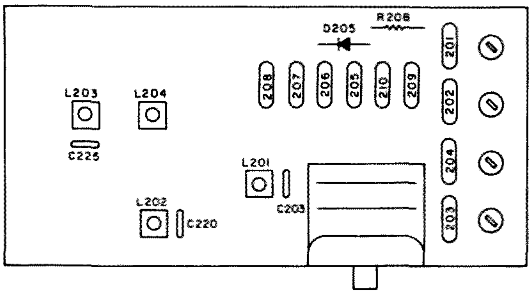


Fig. 1. Xtal-plexer.

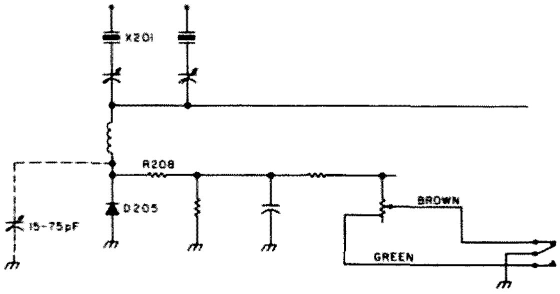

Fig. 2.

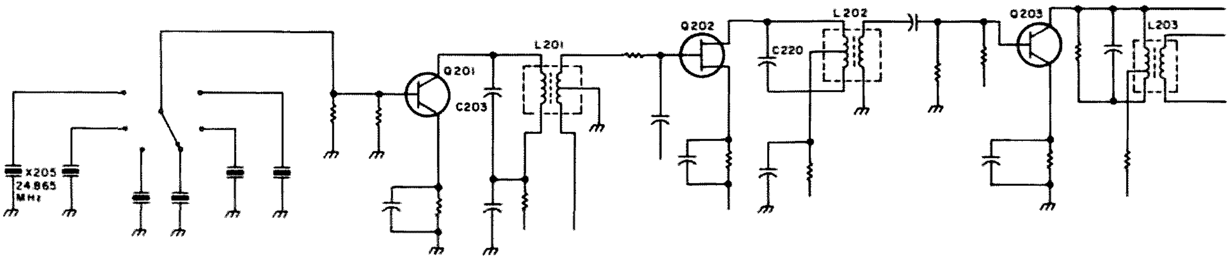

Fig. 3.

band begins at 28.5 MHz, I used the frequency/channel scheme shown in Table 1.

In order to produce the frequencies shown in Table 1, new xtals must be purchased and substituted for xtals x-205 through x-210. Table 2 shows the new xtals that must be installed.

The new xtals can be of the third-overtone type, which is less expensive than a fundamental type. Note that any one xtal will give you four channels, so if you need only 40 kHz of the band, only one xtal needs to be installed.

Installing the New Xtals

First, remove the old xtals directly behind the channel selector. I recommend the use of a solder wick, as the circuit board is very easily ruined by excessive heat. Next, install the new xtals in the proper locations. Note that the xtals are not in order. Locate C203, an 86-pF capacitor, remove it and in its place put a 68-pF mica capacitor. Locate C220, a 15-pF capacitor, remove it and in its place put a 10-pF mica capacitor. (See Fig. 1.)

Tuning Up the Xtal-plexer

Place the channel selector to channel 1. This switches x-205 and x-201 into the xtal-plexer's circuits. If x-205 is a 24.865 MHz xtal as specified, then tune L201 to resonance at that frequency. Measure the frequency and signal amplitude at the gate of Q207. Note that a 14.910 MHz signal is also present at the gate of Q207. If the 14.910 MHz signal prevents you from tuning the 24.865 MHz stage, then ground the source end of C219 (10 pF). Once L201 is tuned, begin tuning L202. (Remove the ground from C219 if you grounded it in the previous step.) The L202 stage should tune to resonance near 39.775 MHz. Measure frequency and signal amplitude at the collector of Q202. Next tune coil L203 for peak output, and measure signal amplitude at the cold end of C227 (1 pF).

Channel	Frequency
1	28.500 MHz
2	28.510
3	28.520
4	28.540
5	28.550
6	28.560
7	28.570
8	28.590
9	28.600
10	28.610
11	28.620
12	28.640
13	28.650
14	28.660
15	28.670
16	28.690
17	28.700
18	28.710
19	28.720
20	28.750
21	28.760
22	28.770
23	28.800

Table 1.

Xtal #	Old Xtal	New Xtal
x-205	23.330 MHz	24.865 MHz
x-206	23.380	24.915
x-207	23.430	24.965
x-208	23.480	25.015
x-209	23.530	25.065
x-210	23.580	25.115

Table 2.

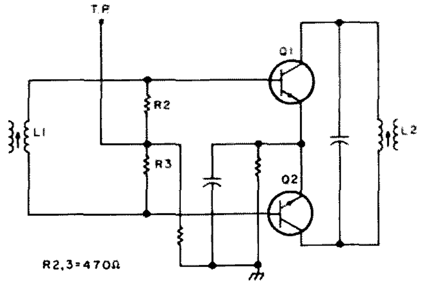

Fig. 4.

Next, tune L204 for peak output, and measure signal amplitude at the base of Q17. Then go back and tweak L202 and L201 for maximum signal at the base of Q17 with the channel selector switched to channel 11 or at the center of your frequency scheme. Tweak L203 again for maximum output.

Receiver Tune-Up

Select channel 1. Inject a modulated signal at 28.5 MHz at the antenna connector or, if a signal generator is not available, connect a 10 meter antenna. Place the mode switch to AM and tune L18 and L19 for maximum audio output or maximum band noise. The S-meter can be used as a tuning indicator. Slowly decrease the injected signal strength, and tune L18 and L19 for maximum receiver sensitivity. This completes receiver conversion. Switch the mode switch to USB and run through the channels; if the band is open, and an antenna is connected, signals should be heard.

Fine Tuning Modification

There are two proven modifications to the fine tuning. One uses the original varactor diode circuit, the other requires that a variable capacitor be added.

Modification 1 is the easiest and requires only that the green wire on the fine-tune pot be moved from the tap to the wiper. The brown and green wires are both on the wiper after modification. This allows the transmit and receive frequencies to track together ± 600 Hz.

Modification 2 requires that a 15-75-pF variable be mounted in place of the fine-tune pot, and that D205 and R208 be removed from the xtal-plexer board. (See Fig. 1.) A wire from the variable capacitor is connected to the circuit board where the cathode of D205 was originally. This modification allows the transmit and receive frequencies to track ±2.5 kHz. (See Fig. 2.)

Transmitter Tune-Up—USB and AM

Place the mode selector

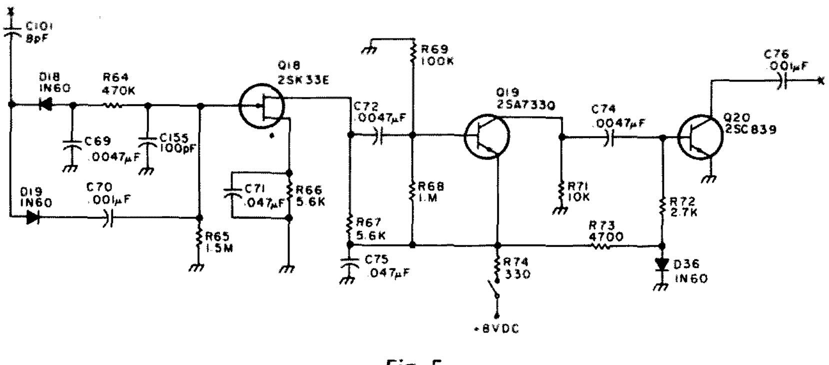

Fig. 5.

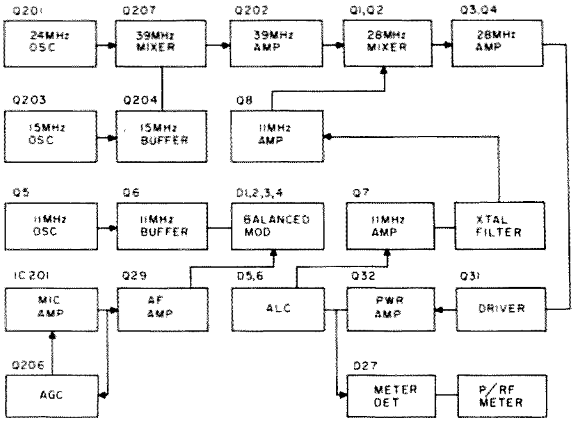

Fig. 6. Transmit USB.

switch in the AM position. Connect a dummy load to the antenna connector through a power indicator. Now, while keying the mike, adjust L2 for maximum output of rf. This will be fairly low, perhaps less than 1 Watt. Next, in order, tune coils L3, L4, L5, L7, and L6 for maximum rf output. In the AM mode, full output power is about 3.8 Watts with 13.8 V dc supplied. Switch the mode switch to USB and whistle into the mike. About twice the rf should be indicated on the output. Remember to check the frequency of the rf at the antenna. Remember also that 28.5 MHz USB is very close to the phone band's edge!

Transmitter Tune-Up—LSB

This part of the conversion is optional. If LSB is desired, follow the next few steps. Change C131 to 36 pF and change C91 to 36 pF; put the removed C91 (39 pF) in place of C94 (47 pF). Place the mode selector in the LSB position. Key the mike, remembering to use a 50-Ohm dummy load on the antenna. Tune L15 for maximum rf. The frequency should be about 17 MHz, depending on the channel you have selected. Tune L16 and L17 for maximum rf while monitoring at the junction of R2 and R3. (See Fig. 4.) Now modulate the rig. An LSB signal should be present at the antenna. Check the receiver for good sensitivity. It may be necessary to retweak L15, L16, and L17 for best results.

Noise Blanker

Lastly, I noted that the SSB-75 does not incorporate a noise blanker circuit, although the SSB-100 does. Actually, the foil pattern for the blanker is on the SSB-75 circuit board, and the components can be added for less than $10.

A schematic of the blanker used in the SSB-100 is shown in Fig. 5. Components are common, but substitution of semiconductors is not recommended. These exact semiconductors are available from Fugi Svea Electronics.

Summary

This collection of notes is provided for your information, and may not work in all SSB-series radios. However, two SSB-75s are now on the air at this QTH and working like champs. Good luck! If you run into trouble during this conversion, drop me a line, and maybe I can help. 73.■

At Last! A Really Simple Speech Processor

—5 dB for $10

Add some punch to your signal.

Jeff Stadelman W9UT
Bob Steingart WB9OEC
Box 38
Pound WI 54161

Amateurs are always looking for ways to add a little extra punch to their signals. I guess it's just a natural inborn ham instinct to want to be louder than the other guy. And, of course, one of the most popular methods to get just a little bit more out of that transmitter is through speech processing.

There have been countless articles written on this type of signal enhancement, but many are very complex and present problems to the casual builder. This processor, however, while very simple and inexpensive, is highly effective. The builder can expect to see a 2-5-dB improvement in signal strength. The total cost of this project should be no more than ten dollars, using all new components.

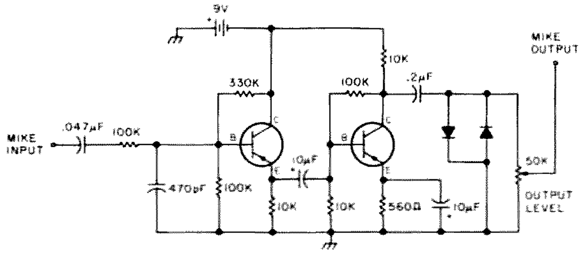

Fig. 1. The processor circuit. Transistors are 2N408, GE2, or Radio Shack RS2004. Diodes are any germanium diodes, such as 1N270.

The processor is constructed on perfboard, wired point-to-point, and enclosed in a metal box. The individual builder, however, may wish to design and etch a circuit board, or incorporate the unit directly into the transmitter. The input, output, and voltage-switching circuits have been left unfinished. The builder may want to incorporate a switching network of his own design.

The authors have used this processor in many contest and DX situations, and have received nothing but glowing reports from listeners. This simple, inexpensive processor should make a worthwhile addition to nearly any station. ■

New Life for Tube-Type Dippers

—simple circuit reads out on your frequency counter

From tube to transistor—without tears.

Randy Prewitt K4LJA
2013 Sherwood Ave.
Monroe LA 71201

Don't misunderstand me. There's nothing technically wrong with the old Knightkit grid-dip meter. It's just that whenever I wanted to measure the frequency of a coil, the ac line cord was too short or I would invariably drape the power cord across a simmering soldering iron, nearly electrocuting myself.

So, something had to give, hopefully the line cord. And it did, but not as quickly as initially planned. About a year ago, I started noticing an abundance of articles proclaiming the miracles of field-effect transistors (FET) and bipolars replacing tubes in many simple circuits. Then the light dawned and I planned my attack. After all, I needed a portable, cordless gdo to take to my beam antenna for measurements, and to get into tight spots in other electronic projects.

Needless to say, not all attacks are successful, and my first few weren't. Oh, I managed to transistorize the beast alright, but ended up with numerous false dips and erratic meter readings. Plus, the dial left much to be desired as far as accuracy goes. Since I had just completed a frequency counter, more lights began dawning.

About the same time that I was mentally abusing myself for being so stupid as to louse up a perfectly good tube gdo just because it had an ac line cord, Fred Teague W4RHJ showed me a breadboard gdo circuit he was playing with. I tried it, making a few modifications for my particular needs, and, amazingly, it worked the first time.

Since I had already stripped the bulky tube components from my

Top view of gdo, showing vertical mounting of perfboard transistor circuit and main tuning.

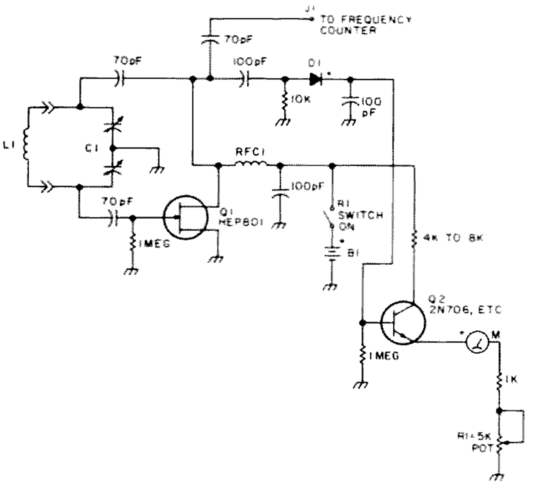

Fig. 1.

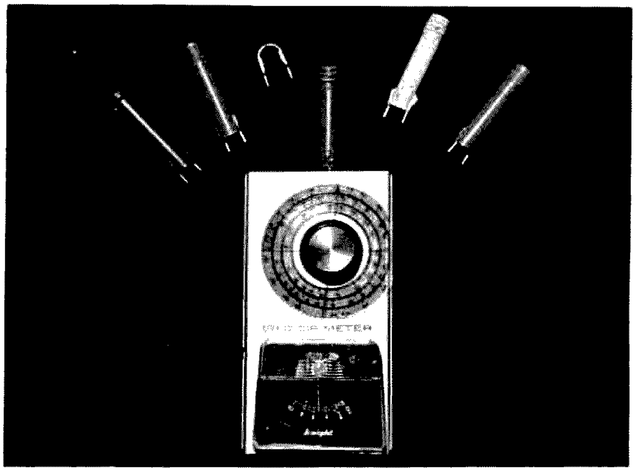


View of converted tube gdo, showing normal selection of coils.

Knightkit, it was a simple matter to clean up the breadboard version and install the small perfboard circuit vertically in the Knight case. About all I kept from the original were the case, coils, variable capacitor, meter, and the combination switchpot.

You'll find the new circuit to be simple, noncritical concerning parts, and reliable if good, sensible rf wiring is followed.

One of the novel features is the placement of diode D1. Through the pick-off capacitor, it rectifies a small amount of rf and drives the meter amp. Many circuits have it reversed, but this method allows using a less expensive transistor since we're dealing with dc and not rf. It makes the circuit less critical, too. Another feature is an rf pick-off used to feed a frequency counter. This allows you to read the dip from the meter and glance over at the frequency counter for the numbers. Super accuracy. Of course, you should retain the existing Knight dial for those times when you're hanging off the tower trying to get a dip on your new beam's frequency. At times like that, you sure don't need another piece of equipment like a frequency counter bonking you in the head as you dangle from the tower.

If you wind your own coils and build the unit from scratch, use ½-inch forms with an RCA pin plug on the bottom and a mating plug on the gdo. The lower frequency coils use thin Litz wire and the higher frequency jobs use #24 wire, progressing to #22 wire for the highest range coil. Using a frequency counter, you can calibrate the dial right on the money.

Personally, I couldn't get along without mine now. And by the way, this tale does have a moral. Actually, it has two. First: Don't throw anything away which can be converted. Second: If the conversion doesn't work, don't despair. A better circuit will come along in the future. Welcome to the future; here's your better circuit. ■

Parts List

L1-L6—Existing coils from Knight grid-dip meter, or custom-wound coils can be wound on ½-inch forms
C1—Dual 50-pF variable, retained from original circuit
D1—1N914, or similar
Q1—ECG 132 Sylvania, or similar HEP
Q2—NPN garden variety
B1—Nine volt battery
RFC—1 mH
All resistors 1/8 Watt, capacitors in pF (mmf) unless specified
M1—Existing meter in Knightkit, or 1 mA basic dc movement
J1—Pin jack

Coil Information

1.5-3.5 MHz	75 turns, pi-wound Litz, three pis
3.0-8.5 MHz	30 turns, 3-pis Litz wire
8.5-20 MHz	30 turns, #24 close wound, ½-inch form
19-45 MHz	12 turns, #24 close wound, ½-inch form
45-115 MHz	4 turns, #22, spaced over 1 inch, ½-inch form

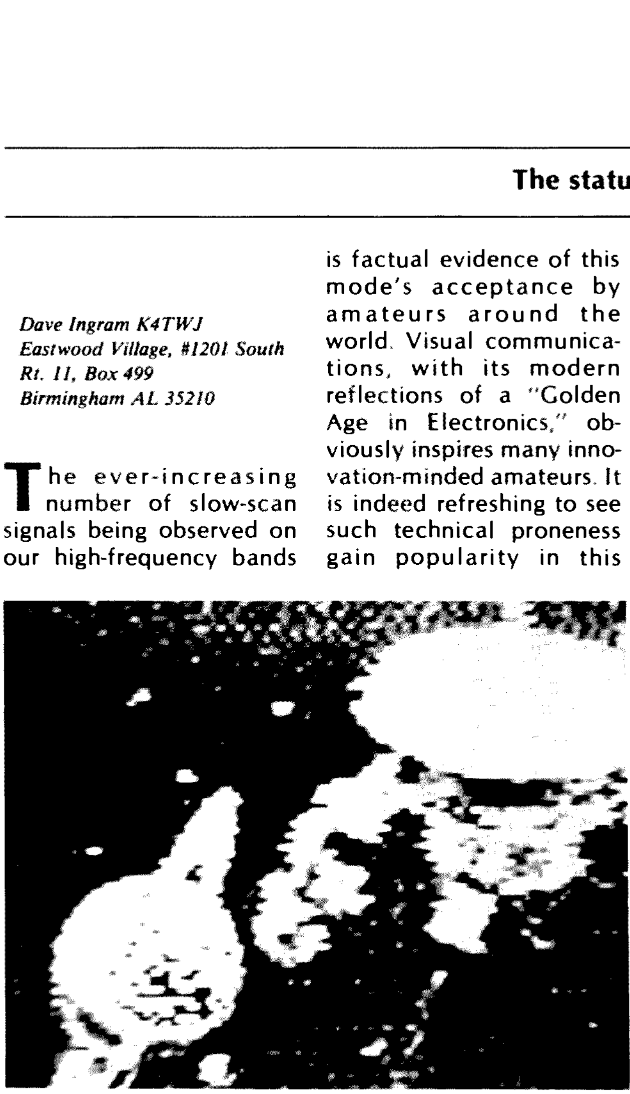
You Ought To Be in Pictures

—here's what the guys on 14,230 are doing

The status of SSTV.

Dave Ingram K4TWJ
Eastwood Village, #1201 South
Rt. 11, Box 499
Birmingham AL 35210

The ever-increasing number of slow-scan signals being observed on our high-frequency bands is factual evidence of this mode's acceptance by amateurs around the world. Visual communications, with its modern reflections of a "Golden Age in Electronics," obviously inspires many innovation-minded amateurs. It is indeed refreshing to see such technical proneness gain popularity in this modern computer age. Many technical and operational expansions have favorably affected the world of SSTV recently. This article is presented as an "update account" of these expansions. Some of the more prominent technical innovations will be considered first, then I will discuss the operational and future aspects of slow-scan TV.



This SSTV picture, which was received from Dick K6SVP, shows the Voyager spacecraft approaching the planet Saturn. The large white object in the top right-hand corner of the picture is a parabolic dish on the spacecraft. The "gear"-looking item on the left of the Voyager is part of the unit's probe. The "snow" at the top of the picture was due to noise on 20 meters.

Digital-Scan Conversion

The unlimited expansions associated with digital scan conversion have definitely established this method as the ultimate technique for serious SSTV work. Home-brew scan converters, however, are becoming somewhat scarce in the US since Robot's Model 400 gained popularity. This is simply because one cannot build a slow-to-fast-scan converter (with its associated 65K of memory) for less money. Building a digital scan converter without the use of prefabricated PC boards is also a hair-pulling experience.

Robot's 400 is perfectly suited for technical expansions, the most promising one presently being dual 65K memories. This approximately $180 addition can be used for implementing real-time color, restricted motion, and special processing of interference-ridden pictures. Dr. Don Miller W9NTP and Dr. Robert Suding WØLMD are presently the leading pioneers in these areas. (W9NTP may still have these "second memories" available. If interested, send Don a large SASE for full details.)

Medium-Scan TV

One of the most outstanding new concepts to affect our world of visual communications recently is the evolution of the medium-scan TV system. This super-expansion of SSTV combines the best features of both the fast-scan and slow-scan worlds and results in a high resolution-motion TV system capable of international communications. The prime instigators of this system are W9NTP, W3EFG, WB8DQT, W6MXV, and WØLMD. Additionally, W9NTP has demonstrated this system to several European amateurs interested in operating

medium scan from their areas. The prime objective of this amateur "special interest group" is to be the first to effect transatlantic communications with live, motion TV.

Technically speaking, medium-scan TV is a 128 horizontal line by 128 vertical pixel double-interlaced system with a 35-kHz bandwidth. There are 7.5 fields transmitted each second, and a 4-bit sync code is used to designate the specific fields. Color may be employed with this system by properly encoding each field with red and green signals while also integrating the black and white components to produce the "Y" signal. Special Temporary Authorization from the FCC has been granted to the previously-mentioned amateurs to permit transmissions of these wideband signals on the high end of 10 meters.

A simplified block diagram of medium-scan TV is shown in Fig. 1. Since narrowband FM is employed in this system, some easily assembled circuits and an ordinary FM receiver replace the station's regular high-frequency transceiver. A Robot 400 or similar scan converter with dual 65K memories is used to decode and reconstruct the received pictures and present them to a conventional fast-scan television.

Simultaneous Audio and Video

Several techniques for multiplexing sound and SSTV have been investigated, but this form of communication hasn't yet gained widespread acceptance. The simplest and least expensive method of multiplexing audio and video involves using a Motorola MC1596 in its conventional AM modulator/demodulator configuration. These circuits are included in recent issues of Motorola's applications notebooks.

Single-Memory, Compatible-Color SSTV

Mike Tallent W6MXV has been developing a single-memory color system which has substantial promise for SSTV use. This system, which is fully compatible with our existing black and white SSTV system, employs slight modifications of the R-Y, B-Y parameters used in conventional fast-scan TV concepts.

Initially, a 737.5-Hz color subcarrier is modulated in quadrature (in phase and 90 degrees out of phase) with color-difference information, while luminance SSTV modulates the regular 1500- to 2300-Hz bandwidth. At the receiving end, a continuously-transmitted color pilot signal is processed and used to reproduce the color-burst phase reference and control clocking of the D-to-A converter. Basically, this concept permits the interlaced and phase-shifted color information to be loaded in main memory along with the regular SSTV. Next, this information is accelerated to fast-scan rates, removed, and used to construct R-Y, B-Y, and Y signals which drive a conventional fast-scan TV.

While Mike's system suffers the same problems associated with our present NTSC (fast-scan) system (high black and white resolution but poor color resolution), it has the definite advantage of low-cost compatible color. This experimental concept may well prove to be tomorrow's accepted method for real-time color SSTV.

This is an SSTV picture of a human eye operation. The operation jig which holds the probe is fitted to the eye during such operations as cutting the pupil area and inserting a new lens. The picture was the first of a series received from Dave W5DUU.

The Software Situation

There is a natural tendency for specialized modes of communication such as SSTV to attract a larger number of technically-oriented amateurs than on-the-air operating enthusiasts. As a result, SSTV developments have outpaced meaningful on-the-air usages. Naturally, we would like to encourage more "applications-oriented" video enthusiasts to join our ranks. If you have ideas or are involved with activities which can be shared with others through visual communications, the world of SSTV is a haven for endless opportunities. Possibly the following brief discussion of some recent amateur accomplishments with SSTV will help spur your thoughts along these lines.

N6V and the gang at the Jet Propulsion Labs were true pacesetters of SSTV programming with their on-the-spot reports and views of Mars during 1977. The JPL gang is continuing these activities during 1979 with SSTV retransmissions from the *Voyager* spacecraft on a mission to Jupiter, Saturn, and Uranus.

Dave W5DUU, an accomplished eye surgeon in Texas, frequently transmits pictures of human eye operations which are fascinating to view. Dave's accompanying explanations

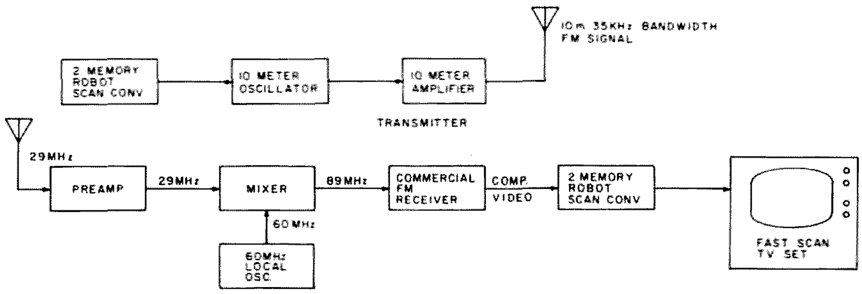


Fig. 1. W9NTP medium-scan TV system which may be used on the high end of 10 meters.

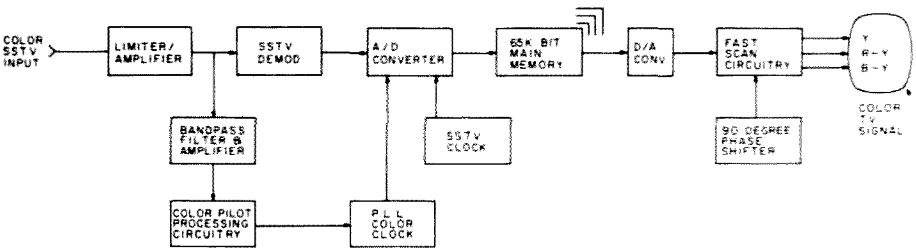

Fig. 2. Simplified block diagram of W6MXV single-memory color SSTV system.

of these operations provide a detailed account of modern optical techniques.

Meanwhile, W1BGW continues retransmitting SSTV pictures received from our weather satellites, W6KZL shows his hydroponic greenhousing, and XE1JOF describes the Mexican pyramids and points of interest in his area.

These examples of SSTV applications illustrate many aspects which are possible when our mode is effectively put to use. We need to see more transmissions of this nature on the HF bands.

ISSS

During early 1978, I began planning to form an International Slow-Scan Society. The prime objective of this organization will be to affect SSTV expansion and acceptance from both technical and operational standpoints on a worldwide basis. Thus far, a number of slow scanners have joined in this effort (providing whatever services are consistent with their interest and ability), and we have established liaison with countries in four of the six continental areas. Eventually, we plan to sponsor our own contests and activities, provide an SSTV "newcomer assistance" service, establish hardware and software library services (which will function like QSL bureau systems), produce a quarterly SSTV newsletter, and much more. Naturally, we need the support of all active slow scanners to ensure that these plans succeed. If you are interested in supporting ISSS, send me one or two SASEs and a brief note describing your particular areas of interest. Your first SASE will be returned when the next ISSS newsletter is produced, and the other SASE will be held until a subsequent newsletter (or specifically requested information) is available.

I would like to hear particularly from amateurs interested in joining my ISSS plans to assist some poverty-stricken areas in our "third world." Some countries are not self-sufficient because their yearly rainfall will not support the needs of their populations. Missionaries and engineers try to teach the inhabitants modern techniques of water engineering—irrigation, contour farming, and so on, but their success is somewhat restricted by a lack of native acceptance. This is an ideal chance for SSTV to prove its merit while also helping mankind!

Getting Started in SSTV

I hope that many non-slow scanners are reading this article out of curiosity, and I would like to encourage you to investigate the fascinating world of SSTV. An "arm and leg" investment isn't necessary for one to equip his station with slow-scan capability. The W6MXV monitor, for example, performs very well and costs approximately $100 to build.

Another great home-brew unit is the WØLMD video-sampling monitor. Larry Prior WA9MFF sells PC boards for this outstanding P-7-type unit. Amateurs interested in "going first class" can purchase a Robot 400 for approximately $700 and be set for any innovations that may evolve in the foreseeable future. If you don't care to purchase a commercial video monitor to use with the 400, Robot's optional VHF oscillator will allow this scan converter to drive your regular TV set via its antenna terminals. I've used this method for several months with my 400 and Sony TV, and it works great.

Summary

The world of SSTV continues to be a wide-open field for amateurs interested in enjoying new modes of communication. It has reached a high degree of technical advancement and become an accepted mode of long-distance visual communication. We are now interested in using this mode to its fullest capability and sharing our world with others.

Whether you are a technical innovator or operating enthusiast, consider this article an open invitation to join our ranks. If you need additional information or assistance, simply contact our SSTV net which meets each Saturday at 1800 GMT on 14,230 kHz . . . or ask any SSTVer. ■

Belleair Bluffs FL 33540

How to Toot Your Own Horn

—and stay on key

Try out this simple pitch generator.

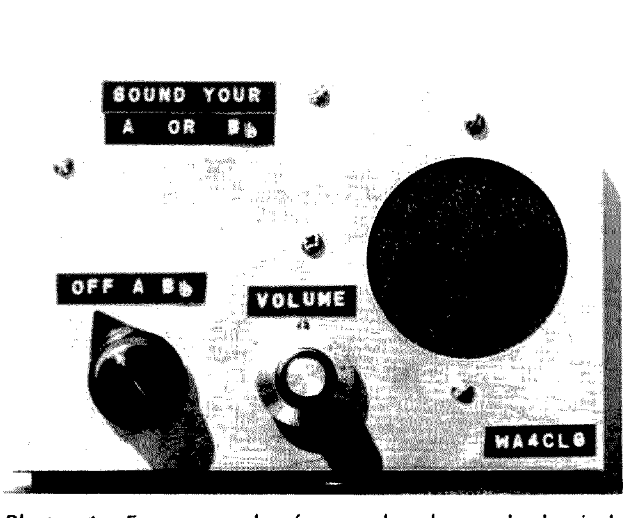

Photo 1. Front panel of completed standard pitch generator.

Chances are that if you are not a musician, then you probably have a "harmonic" who is. But if not, you just gotta have musical relatives or friends! So, you are bound to find some use for a simple electronic circuit which produces an accurate "A" or "Bb" for tuning orchestra or band instruments.

Construction is easy, and will not take much time to complete. See Fig. 1. The oscillator is quite standard; it is one shown by Jan Crystals on their catalog sheet. The oscillator produces 4400 kHz or 4662 kHz.

Through the use of four 7490 ICs, a dividing circuit is set up whereby the oscillator frequency is divided by 10,000. This gives you 440 Hz and 466 Hz. These are, of course, in the audible range and are the musical tones "A" and "Bb"—tuning frequencies used by band and orchestra instruments.

The photos and drawings are self-explanatory. You should have no problem putting the components on the .1" x .1" perfboard (Fig. 2). Also, a drilled PC board is available for $5.18 postpaid from Rick Allran, PO Box 974, Waynesville NC 28786.

I used sockets for ICs and the transistor. It is recommended that you use wire-wrap IC sockets since the extra length of the terminals allows easier solder attachment of the wires. Of course, you can wirewrap if you like. An octal

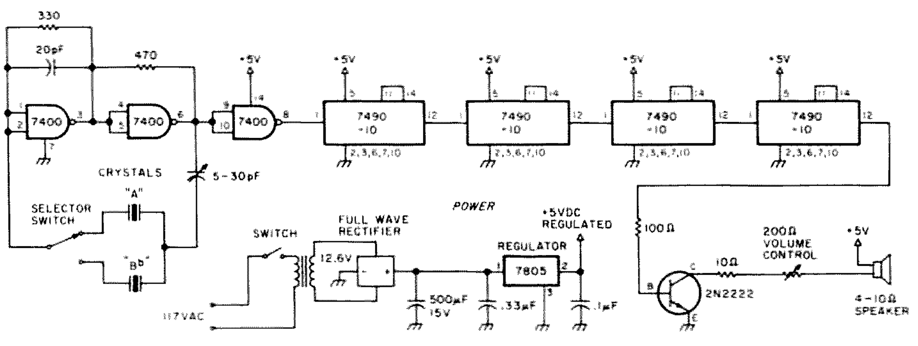

Fig. 1. Schematic of pitch generator and power supply.

socket is used for mounting the two crystals. I removed the unused socket terminals. Proper drilling of the perfboard allows you to mount the octal socket by bending the terminals.

The crystals I used were not expensive specials—simply .005% accuracy. They are in the $2 class.

When the perfboard is completed, you can mount it and the other components in any suitable cabinet. The power supply is my version of a compact "Japanese" assembly, mounted on a 3-lug terminal strip. Photo 2 and Fig. 3 show this neat setup. The voltage regulator socket (a transistor socket), filter capacitor, rectifier, and bypass capacitors, are all mounted together. The cabinet acts as the heat sink for the voltage regulator.

If you have trouble finding a cabinet, as I did, the Radio Shack chassis in the parts list is an economical substitute. I closed the back of the chassis cabinet with a piece of perfboard. You can add a ¼-Amp fuse to the 120-volt ac power input. For true portability, the unit could be powered with batteries, in which case you should use the alternate ICs listed—the 74C00 and 74C90s—because their current drain is less.

I selected the volume control value to allow some audio to be heard even when set at minimum. This helps you to remember to turn off the unit.

When you have the project buttoned up, you are ready to sound a near-perfect "A" or "B♭". You can be sure you're in tune when you match this tuner.■

A Junk-Box HT Charger

—power to the portables

Very nice at a $5 price.

Sunny Mitchell WB9JLY
Box 438
Sparta WI 54656

Wouldn't it be nice to have a charger for the Wilson HT on the bedside stand, in the living room, garage, or wherever else you might like to monitor? This would allow you to listen and still keep your batteries charged so you could pick it up and go.

I decided that I would like one, so I checked the spare parts department (junk box) for necessaries and home brewed a cheap charger that works as well or better than the factory model.

Its features include:

Constant charge rate in both high and low mode;

Low charge rate adjustable so batteries will stay charged while monitoring;

Use of voltmeters and milliammeters if desired and available, but they are not necessary (more on this later).

Construction

Any small box will hold the parts; I prefer the 5¼"× 6" × 3" box from Radio Shack. The transformer should deliver about 25 volts at the secondary. I found one with 48 volts center-tapped and used one side for 24 volts. A bridge rectifier is used. The capacitor value is not critical; in fact, you can even leave the capacitor out and the charger will work. I measured the current drain of my Wilson (in standby) and found it to be 25 mA instead of the 14 mA stated in the specs, so I adjusted resistance to give 30 mA on low charge and 55 mA on high charge. This is about the correct rate (50-60 mA) for slow-charging AA nicads. You could fast-charge at 150-200 mA without any problems, but I think it is easier on the cells to use the slow rate of about one-tenth the Amp-hour capacity.

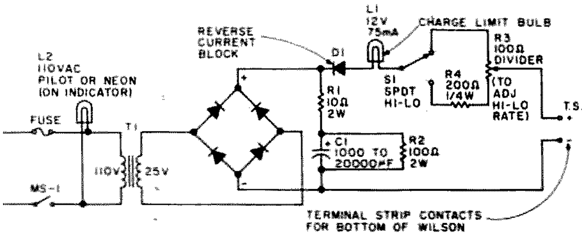

Fig. 1.

A 0-15-volt dc meter is a helpful option across the output terminals to determine the condition of the cells. At full charge, the meter will show approximately 14 volts with the HT in the charger. Also, the condition of the cells is determined by the voltage drop observed by transmitting with the Wilson in the charger. If the cells are good, a 2½-Watt HT will cause a voltage drop of ½ to 1 volt. If the voltage drop is much greater, it is probably caused by a weak or dead cell. A milliammeter is an option, but one should be used to adjust the values of resistance to set the proper charge rate when constructing the charger.

The problem of contacts for the charge terminals on the bottom of the Wilson is solved by using a barrier terminal strip and spade lugs bent to 90 degrees with a short length of #12 solid copper wire soldered into the spade lugs. The hole in the top of the case is cut with tin snips and the edges are smoothed and covered with rubber molding or tape. Pop rivets are handy for mounting the barrier strip and transformer, and a hot-melt glue gun can be used to hold some small parts. The 100-Ohm voltage divider makes adjustment of high-low charge rates simpler. Be careful to handle the 110-volt primary side of the circuit with care. I advise grounded plug and chassis, a fuse at one Amp, and the use of a microswitch to turn the primary on/off when the charger is in or out of use.

It is also a good idea to insulate or cover all 110-volt connections inside the case. Don't forget the rubber grommet to protect the power cord and to provide some sort of strain relief (a knot will do).

Summary

The fourth charger I built was completed in about two hours from mostly junk parts, and it works like a charm. So get busy and have some fun building one or more. They are not critical; just watch the milliamp charge rate. Considering that the commercial version is about $40, these are very nice at about $5, depending on what you find in your junk box. I found the box, which I bought, to be the most costly item at about $4. ■

Protect Your Home-Brew Panels

—no more spraying

The slick way to slick fronts.

Michael Black VE2BVW
16 Anwoth Road
Montreal, Quebec
Canada H3Y 2E7

So you've finished your latest project. Now you're ready to label it. A popular way to do this is to use rub-on lettering, such as Letraset. This gives a professional look to your work, something which is impossible with label-makers. But with Letraset, your project will soon look awful if you don't protect the lettering from scratches. To overcome this problem, many builders spray their panels with Krylon or some equivalent. This is the method I used until I came across one which I believe to be better.

The method I use now is to cover the panel completely with the material which is used to cover identification cards and other things. Basically, this stuff is clear plastic with an adhesive backing. While more expensive than using clear spray, the method does have the advantage that only a very sharp instrument can scratch either the lettering or the panel.

The material I used is called "Protecta." It costs me $2.50 for a sheet 18 by 72 inches. This, or another brand, should be available just about anywhere. Just go to your local stationary store and ask for that adhesive plastic stuff which is used to cover ID cards and books.

Now for some info on using this panel-protecting method. First, be sure that the panel is clean and that all the holes have been deburred. Is the lettering just as you want it? Adhesive plastic is fairly permanent. If you want to remove it later, you will have to discard it, and you may even pull off some of the lettering.

The next step is to cut the plastic to size, with about ¼ inch extra on each side. Pull the paper backing from the plastic. Apply the plastic to the panel slowly and evenly. Watch out for air bubbles. If you see any of these, pull off the plastic a bit and reapply it with some pressure. With luck, you now have the plastic down with no air bubbles.

Go over the panel, applying pressure all over. Turn the panel over onto a solid surface. Use a sharp knife to cut the excess plastic from the edges of the panel. Once again turn the panel over, so that the plastic is facing you. With the sharp knife, clear out the holes. Use a downward motion and cut the plastic right at the edges of the holes. For the smaller holes, the knife may not work too well, and I'd suggest using a sharp, tapered instrument such as an ice pick. Simply push the implement through the plastic until it fits the hole. Now your panel is ready.■

Now You Can Possess Instant Recall

—don't tell 'em the computer helped

The call is the key.

Ken Winters WB5UTJ/N5AUX
5307 Marshfield Court
Arlington TX 76016

How often have you been driving along monitoring your favorite frequency and heard someone with a familiar callsign, but you just couldn't remember the name that went with it? And if they gave you a call, they always threw your name in along with your call, of course. Sometimes it seems like a deliberate challenge designed to see if you can come back with the right name. Wouldn't it be nice if you could always respond with the name as well as the callsign the first time? Wouldn't it be even better if you could return a comment or ask a question about the fellow's hometown, favorite topic, or some other subject close to his heart?

Those of you with instant and total recall may be excused now. Described in this article is a recipe guaranteed to help the rest of us. Those of us, that is, who have either a computer or at least access to one. The two programs listed here are designed to provide the capability of storing, maintaining, and listing in alphanumeric order by callsign, the call, name, and telephone number (or city) of all the mobile contacts you've made and wish to remember. Along with all that information, there is also room for comments and remarks about anything, such as the special interests of each of those operators (e.g., RDF, DX, computers, flying, sailing, etc.).

The goal is to produce a list of stations worked by a mobile operator in a format that is convenient to use while driving (if that's possible). In order to be convenient, the list must be printed in alphanumeric order by callsign on standard-size paper (8.5 by 11 inches). The alphanumeric sequencing is obviously required if a call is to be found easily in any list. The notebook-size paper lends itself to use on a clipboard, often standard equipment for the mobile operator.

The BASIC programming language was chosen for the simple reason that BASIC is the most machine-independent language commonly used on both commercial and hobby computer systems. The particular version shown here uses video display terminal (VDT) cursor positioning control during the data entry and file maintenance functions. Also, the VDT "control keys" may be used as a shortcut to stopping the program or for bypassing the "change" function. More about these features later. If your system does not support these special features, the appropriate program statements may be easily modified without changing the logical operation of the programs. The only other statements that may need minor changes are the input/output statements (READ, WRITE, and PRINT) where, again, ad-

vantage was taken of the extensions available on my own particular system.

As written, the "file maintenance" program requires about 1K of memory, and the listing program needs about 700 bytes. Each data record consists of from 6 to 58 characters, depending upon how many actual characters were entered for each record. Even on systems that support only fixed-length records, a typical floppy disk will still have enough room to store well over a thousand different contacts. Remember, the idea is to produce a listing for mobile contacts, not your entire log.

The key to the whole operation is using a direct-access (also called a random-access) disk file with the callsign being used as the "key" to each record in the file. The file management part of the operating system software automatically keeps each record in the proper sequence by "sorting" the keys as each new record is added to the file. The keys are kept in one area of the disk and the rest of the data in each record is kept in another area contiguous to the first area. Both areas together comprise the whole data file.

Although there are several techniques used by different systems in handling direct-access data files, the result is basically the same. Each record may be retrieved directly without scanning the entire file looking for the particular record desired. This obviously saves a lot of time getting any specific record. At the same time, the fact that each record has its own unique key eliminates the possibility of duplicate records being stored in the same file. Still another advantage of direct-access files is the fact that no separate sorting of the records is required if the records are to be listed in order by their keys. By starting at the beginning of the file and reading it sequentially without specifying any key, all of the records in the file may be read and printed in alphanumeric order by callsign (key) automatically, since the file management system uses the keys area (usually called the "Directory") of the file to get to the physical records anyway.

File Maintenance

File maintenance simply means adding new records or changing or deleting old records in a data file. Program statements 0010 through 0502 in the file maintenance program define the names of the data items to be used in the program and OPEN the data file where all the records containing the information about the mobile contacts will be stored. Statements 100 through 1050 clear the VDT screen and display the heading information which indicates the name and description of the program being executed as well as the date. Each column of information is labeled with the appropriate name. The two-letter sets enclosed in apostrophes are special print control commands for output devices such as the printer and VDT. The CS means "Clear Screen" and is valid only for the VDT. LF means "Line Feed" and causes a blank line to be printed on the printer or displayed on the VDT.

Many computer terminals have special keys called "function keys" or "control keys." These keys may be used as a shortcut method of indicating specific actions to be taken by a program if that program has the ability to interpret them when they are used by the terminal operator. Since this program allows the operator to use these special keys, the actual functions that some of them are programmed for are also displayed when the program begins.

Program statements 2000 through 2440 handle the actual data entry portion of the file maintenance function. Each of the four data items is entered separately, and each is terminated by pressing the carriage return key (CR). The variable (data item) named "F$" was initially defined in statement 0070 to be a string of 30 characters. A very special character ("Control-Period" on my terminal) was included in the DIMension statement for F$ between the quotation marks following the size specified for that data item. This special character does not exist on the printer used to list the program, but it does appear on the VDT screen and looks like the cursor, which, on my own terminal, is a solid-looking block that entirely fills one character position. Actually, this is an "inverted period," but the dot representing the period is so small, it's almost invisible. Several of these characters displayed together look like one long, continuous cursor. Although entirely unnecessary, this little trick enhances the aesthetic quality of the display and emphasizes the particular data field be-

Fig. 2. Program listing—alphabetical listing.

ing requested by the program.

The first thing the program requests is a callsign. When a call is entered, the program verifies that the call does not exceed six characters in length (the maximum size defined for the keys in the data file). If too many characters are entered, the program rejects the entry and requests the callsign again. Each time a call is requested, the VDT audible "beep" signal is sounded by the RB command included in statement 2100. RB means "Ring Bell," and, even though that name came originally from the older teletypewriters which actually did have a bell inside, the name stuck and is used to indicate the "beep" signal used on most video-type terminals.

I might mention, by the way, that, even though this program is intended for use with a video terminal, it will run on hard-copy terminals if the statements containing "F$" are simply removed.

Automatic Mode Change

When a valid callsign is entered (actually, any six characters will be accepted), the program immediately checks the data file to see if that callsign had been entered previously. If it is a new call, the next data field is "lit up" (or underscored, if your terminal uses the underscore character for a cursor) and a name can be entered. The next field may be used for either a telephone number or city name, and the last field may be used for any comments you may want to remember about that particular operator. Each new line entered remains on the screen until 20 lines have been entered, at which time statement 2020 sends 20 "Line Delete" (LD) commands to the VDT at row 0, line 5, causing the last 20 lines entered on the screen to be "scrolled" up and out of sight. This prevents the heading information at the top of the screen from being lost after the last line on the screen has been used, since most VDTs automatically scroll all the lines up one line each time the last line is used.

The process continues until a call is entered that is already "on file." When this happens, the information previously entered for that operator is displayed under the appropriate column headings. The callsign is then displayed again on the next line down and the program requests something to be entered in the "name" field. If the information displayed on the previous line is correct as is, you can simply press the "Control-II" key, and the computer will leave that record unchanged and request another callsign. If your terminal doesn't have function keys, the program will accept a single asterisk (*) as the indication that the record displayed is not to be changed. If, however, you do wish to change anything in that record, simply reenter each of the three remaining data items as they appear in the line above, making the changes as desired. Upon receipt of the last item, the old record is replaced by the new information and another callsign is requested. Simple.

If you wish to completely delete any particular callsign from the file, just enter the callsign. When that record is found and displayed on the screen, enter the word "DELETE" in the name field. The program will remove that record completely from the data file and display the word "DELETED" by that line on the screen (statements 6000 through 6040), and then request another callsign.

Typing the word "END" (or hitting the "Control-IV" key) when the program is requesting a callsign will terminate the file maintenance program. Before it stops, however, it will ask if you want a new list to be printed immediately. If you enter "YES" or "Y", the second program will be executed automatically, saving you the trouble of having to run it yourself. This allows you to enter several new contacts or make a few changes as convenient, without actually producing a complete new listing each time you run the maintenance program.

Printing the List

The second program may be run separately whenever an updated listing is desired, as well as automatically at the end of the file maintenance pro-

Fig. 3. Sample run of the mobile QSO list.

gram. Having two separate programs keeps the amount of memory required to a minimum. The listing program simply READs the previously described data file sequentially by callsign (key) and prints the information stored in each record in a format I have tried and found to be most convenient to use while operating mobile. As previously mentioned, each record is automatically stored in alphanumeric sequence by the file management system. Thus, no separate sorting of the records is required. Each record is read sequentially and printed in callsign order.

It is possible (and actually quite easy) to have the program rearrange each callsign in such a way that the sorting order is the same as that used in the *Callbook*—that is, all calls in the same call area listed together. However, this method did not seem to have any advantage for the mobile operator who needs to locate a specific call quickly and easily. Although I would not want to see the *Callbook* listed this way, it does speed up the search if you include the call area in the prefix and keep all the Ks, Ws, WBs, etc., together in this kind of list. I also found that printing a space between the prefix and suffix of each callsign greatly improved the readability of the list. Still further improvement was obtained by leaving a blank line between each different prefix group. The listing program simply skips a line whenever there is any difference between the first three characters of the next callsign to be printed and the first three characters of the last callsign printed. The combination of separating the prefixes and the suffixes and leaving a blank line between each different group makes it extremely easy to locate a particular call quickly (assuming, of course, that the call is in the list).

You will probably notice from the prefixes and some of the remarks in the sample listing that it was compiled from contacts in the Dallas-Fort Worth "metroplex" area. Certainly there are no restrictions on how the list is used. If I had been equipped to operate 75 or 40 meter mobile, I think the list would have been even more valuable.

There are always tradeoffs to be considered when writing new programs. One touch of laziness must be admitted here. I did not bother to do any "processing" of the callsigns, except to ensure that none were longer than six characters in length. I also chose to manually enter a blank at the beginning of all 1 × 2 and 1 × 3 calls in order that those would be listed in the "proper" sequence. This could have been taken care of by the program, but the extra program steps did not seem justified based on the fact that it is so simple and easy to just enter the blank when entering such a call.

The listing program prints 50 calls on each page and puts a sequence number on each line down the right-hand side of the listing. Since the printer I use has the ability to produce "Expanded Print" (EP) for any specified line, I used this feature to print the heading line at the top of each page. Each of the four data columns is labeled, of course, and each page is consecutively numbered. If you don't have a separate printer on your system, you can easily change the listing program to print the list on your terminal if it is the hard-copy type. ■

Calcu-Trip

—a program for the open road

Silence those questioners.

"Did you make good time?"

"What route did you come?"

"When did you start?"

"How long did the trip take you?"

"How fast did you drive?"

The first half-dozen questions after every trip home have to do with the trip itself. If this has happened to you, on trips home or anywhere else, you know that most of the curiosity can be satisfied with average miles-per-hour—and then you can get on to less mundane matters.

Here's a simple-minded program for your HP-55 calculator, adaptable to other programmables, which will answer the questions. *RCL 7* provides the last calculated average mph, *RCL 6* provides total accumulated rest stop time, *RCL 1* helps you remember when you started, and *R4 minus R0* tells you the miles you've covered.

The next time you arrive, you can walk in prepared—with calculator in hand. Better yet, hand your HP-55 to the curious and let them figure it out while you wash the trip off your face! ■

Display Line	Code	Key Entry	Comments
00			KEY IN current odometer reading & KEY R/S.
01	33	STO	Stores current odo reading in R4 for use later in
02	04	4	calculation.
03	84	R/S	KEY IN current time in format HH.MMSS.
04	33	STO	Stores current time
05	02	2	in R2.
06	34	RCL	Recalls starting time and subtracts it from
07	01	1	current time to determine time since trip
08	32	g	began, still in format HH.MMSS.
09	41	H.MS-	
10	31	f	Converts time since trip began to
11	01	H←	decimal hours.
12	33	STO	Stores this in R5.
13	05	5	
14	34	RCL	Recalls accumulated time out
15	06	6	from R6,
16	31	f	converts it to decimal hours, and
17	01	H←	subtracts it from time
18	51	-	since trip began.
19	33	STO	Stores active driving time
20	05	5	in R5.
21	34	RCL	Recalls current odo reading from R4
22	04	4	and then
23	34	RCL	recalls beginning odo reading from
24	00	0	R0 and subtracts to get miles traveled.
25	51	-	
26	34	RCL	Recalls active driving time from R5 and
27	05	5	divides it into miles traveled
28	81	÷	to derive mph average.
29	33	STO	This is STOred in R7 for later recall
30	07	7	by hand if desired.
31	24	FIX	Fixes one decimal place (but by modifying
32	01	1	step 32, any number of places can be used).
33	-00	GTO00	Returns program to beginning.

At Start of Trip:
A. STOre starting time in format HH.MMSS in R1.
B. STOre base odometer reading in R0. For cars with a trip odo, this can be left as 00.00, or car's accumulated odo can be used.
During Trip:
C. If you want mph averages based only on driving time, add each rest stop in format HH.MMSS to R6. (RCL 6, KEY IN latest time out, f, H.MS+, STO 6.) Ignore this step if you want overall average mph regardless of stops.
D. To calculate current average mph, KEY IN current odo reading and punch R/S. Then KEY IN current time (HH.MMSS) and punch R/S again. OUTPUT will be average mph attained.

Charging Up the WE-800

—a convenient alternative

External operation, internal charge.

The Wilson WE-800 is a versatile, synthesized two meter FM portable transceiver. It operates from an external 13.8-volt source or internal nicad batteries with the mere flip of a switch on the rear apron. Unfortunately, there is no provision for charging the nicads while operating from external power. Anticipating that this would be a useful feature, I immediately went to the books to find a suitable constant-current charging circuit.

Experiments were run using a series current-limiting resistor while charging the nicads from a 13.8-volt regulated power supply. Various resistances ranging from 10 to 36 Ohms were tried, but in every case the starting current was either much too high (100 mA plus) or it dropped off rapidly to well under 50 mA within the 16-hour charging period. (My GE nicads specify a charging rate of 40-50 mA for 16 hours.) Experiments with various pilot lamps in place of the resistor yielded much less variation between the starting and fully-charged currents. Either a 47 or a 1847 bulb (6.3 V, 150 mA) produced charging currents in the 50-mA range. I found that individual batteries, even new ones of the same make, may affect the charging rate and it is wise, therefore, to substitute batteries and monitor the charging rate during the experimental period.

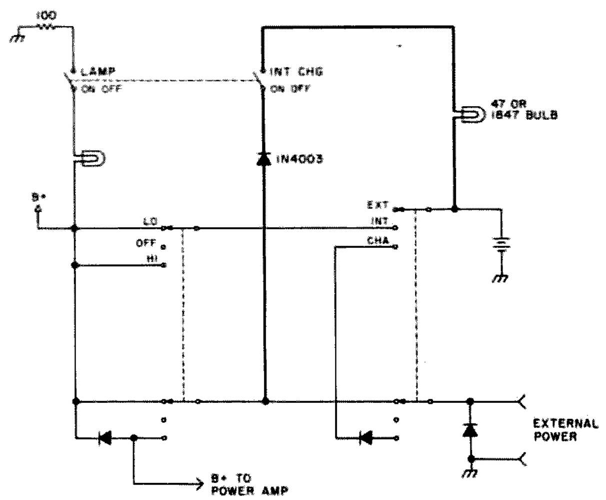

Fig. 1. The new circuit is shown in bold.

Fig. 1 shows the final charging circuit. The 1N4003 diode prevents current flow from the nicads to the external power source. The dial light on-off switch is used also to turn the internal charging circuit on and off. Just remove the existing wires from one side of this switch and use that side to control the charging function. Nicad memory dictates that the batteries should be fully discharged before full recharging, and this switch allows controlled charging. With the circuitry shown, the nicads charge if the charge switch is on, even if the rig's power switch is turned off. When the power switch is turned off, the nicad charging current can be read directly with a milliammeter in line to the external power socket.

The charging current to discharged nicads starts at approximately 75 mA and drops slowly to approximately 50 mA over four hours. This rate holds for the remaining 12 hours. Very similar results are obtained in the car, but there is reduced charging current until the engine and alternator are running. This is because the charging current is determined by the relative voltage of the charger and chargee.

Incidentally, the Wilson WE-800 Owner's Manual does not contain a caution against charging the nicads directly from a regulated power supply, and it probably should. A charging current well in excess of 150 mA was measured with this direct hookup.

With the modified WE-800, I can operate two meters at home or in the car while the nicads are simultaneously charging. With a little imagination, similar circuitry could be installed in almost any nicad-equipped rig. ■

Where Have All the kHz Gone?

—are ham bands an endangered species?

Prophets of doom vs. masters of deceit.

Paradise lost; that could be the story of our beloved old 40 meter band. What fun we had! If we wanted to work Australia, we looked from 8000 to 9000 kHz, Europe was from 6000 to 7000 kHz, and the USA hams had 7000 to 8000 kHz exclusively to roam around in. We never heard of intruders, and all was beer and skittles until the ARRL started to "preserve" our bands.

Let's take a graphic look (Figs. 1 and 2) at our workhorse bands that were admittedly preserved by the ARRL. They very graciously (and with great publicity) provided the sum of $100,000 to protect bands that were worth a king's ransom, bands so valuable even today that you cannot put a price on them.

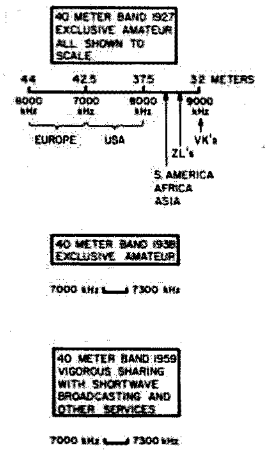

Fig. 1.

Pretty gruesome, isn't it? But that "ain't" the total story. When shortwave stations began to appear in our bands, our vigilant ARRL, with great poise and indignation, coined the word "intruder" and established the intruder watch. The purpose of this is to enable you to let off steam and have you think that something is being done about the problem. This intruder watch is a real exercise in frustration. So you report them, and years later they are still going merrily on their way. You know why? Because no one ever objected at the proper time to their being there. International law says that these frequencies are requested from and assigned in Geneva and, after assignment, other countries have a year to object to the allocation before it is final and the station goes on the air. After the station is on the air, it's too late.

This intruder thing may break our backs at WARC '79. Believe it or not, the dear broadcasters are now looking at *us* as intruders and want to throw *us* out! The extent of the intruders on 40 meters at night is horrendous and is rendering the band useless. Now you are begining to see them appear in daylight. At night, 40 is one mass of heterodynes and signals.

Have you ever wondered just how many stations are in there? *World Radio and TV* lists 414 stations all within 7000 to 7300 kHz. There are powers listed from 10 kW to 250 kW. Ninety percent of the powers are listed as 100 kW, 8% are listed as 250 kW, and 2% are over 50 kW. The Voice of America has 40 stations in this band, with powers of 100 kW to 250 kW. It's no wonder we hear a raft of intruders!

Our USA broadcasters took 100 kHz of our 160 meter band, and recent events indicate that they are going after more of this band. Other bands have gradually disappeared. Ham radio has been, and is, being piecemealed to death. After each WARC (and between some), we lose kilohertz and privileges. We are forced to develop new technology to cram more and more of us into a smaller and smaller space. It won't be long before we will have to develop "negative frequency." It's sad, and a sad commentary on our ability to preserve our bands.

Our dear ARRL writers have labeled men like me "prophets of doom." I have a name for them: "masters of deceit."■

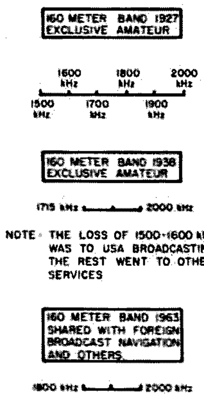

Fig. 2.

June 1979

Novice, QRP, 200 w, deluxe — good, better, best — $299, $369, $399, $699, $869, $899, $1069. TEN-TEC has them all. A choice of seven HF transceiver models — a choice of power levels — a choice of operating features (and accessories) for beginner or old timer. Best of all, there's a wide choice of prices to fit every amateur budget.

TEN-TEC "OMNI" TRANSCEIVERS — REALLY CHOICE.
Top of the line. Deluxe in every respect. Deserving of a place in the finest of operating positions. All solid-state 100% duty cycle 200-watt final amp.; 8-bands (160-10 m plus convertible 10 MHz and "Aux" band positions); broadband design for no tune-up; built-in VOX and PTT; built-in Squelch; 4-position CW-SSB filter and 8-pole crystal filter with separate mode switch to permit using all filters in all modes; 2-speed break-in; 2-range offset tuning; optimized sensitivity from 2 μV on 160 m to 0.3 μV on 10 m; greater dynamic range (typically better than 90 dB) plus PIN diode switched 18 dB attenuator; WWV at 10 MHz; front panel control of linear/antenna bandswitching; phone patch jacks; "timed" crystal calibrator (on "A" model only); zero-beat switch; SWR bridge; adjustable ALC and sidetone; dual speakers; plug-in boards; "clamshell" aluminum case with black vinyl covering plus warm dark metal front panel; full shielding, optimum size for convenient operation: 5¾"h x 14¼"w x 14"d. Model 545 OMNI-A with analog dial, only $899; Model 546 OMNI-D with six 0.43" LED digital readouts, $1069. Model 645 keyer, $85, Model 243 Remote VFO, $139, Model 248 Noise Blanker, $49, Model 252MO AC Power Supply, $119.

TEN-TEC "ARGONAUT" TRANSCEIVER—QRP CHOICE.
The challenge and excitement of working the world on 5 watts. And every feature you need: all solid-state; 5 bands (80-10 m); full amateur band coverage SSB/CW; sensitivity less than 0.5 μV; offset tuning; 4-pole IF crystal filter, 2.5 kHz bandwidth; analog dial; vernier tuning; automatic sideband selection; built-in speaker; 5-watt input to broadband push-pull final amplifier; PTT; full CW break-in; adjustable sidetone volume and pitch; built-in SWR bridge; TVI filter; plug-in boards; small and light weight enough to go anywhere (4½"h x 13"w x7"d and 6 lbs.). World beating price, too: Model 509 only $369; Model 210 AC Power Supply just $34.

TEN-TEC 540/544 TRANSCEIVERS—POWER CHOICE.
200 watts from the bottom of 80 m to the top of 10 m — SSB or CW. No compromise from the leader in solid-state HF technology. Instant band change without tune-up; sensitivity 0.3 μV; offset tuning; 8-pole crystal-lattice filter; WWV at 10 & 15 MHz; push-pull solid-state final amp.; 100% duty cycle; adjustable ALC with LED indicator; built-in SWR bridge; PTT; full CW break-in; adjustable sidetone pitch and vol.; zero-beat switch in Model 544. Choose the value leading Model 540 with analog dial and built-in 25 kHz pulsed calibrator for just $699 or the Model 544 with six 0.43" LED digital readouts for $869. Model 240 160M converter, $110; Model 262M AC Power Supply with VOX, $145; Model 252M AC supply only, $119.

TEN-TEC CW TRANSCEIVERS—BUDGET CHOICE.
The "Century 21" series. Unique. Modern technology with old-fashioned value. Fine performance, reliability, and simplicity of operation, all at low cost. Win raves from novices and confirmed brass pounders alike. All solid-state; 5 bands (80-10 m) full amateur band coverage; receive CW and SSB, transmit CW; sensitivity 1 μV or less; offset tuning; 3-position selectivity (2.5 kHz, 1 kHz, 500 Hz); 70 w input to push-pull Class C final amp.; broadbanded for no tune-up or resonating; full break-in; adjustable side-tone level; built-in AC power supply. Choose Model 570 with analog dial for only $299; Model 574 has a 5 LED digital readouts for only $399.

The choice is all yours when you choose TEN-TEC HF transceivers; see your nearest dealer or write for full details.

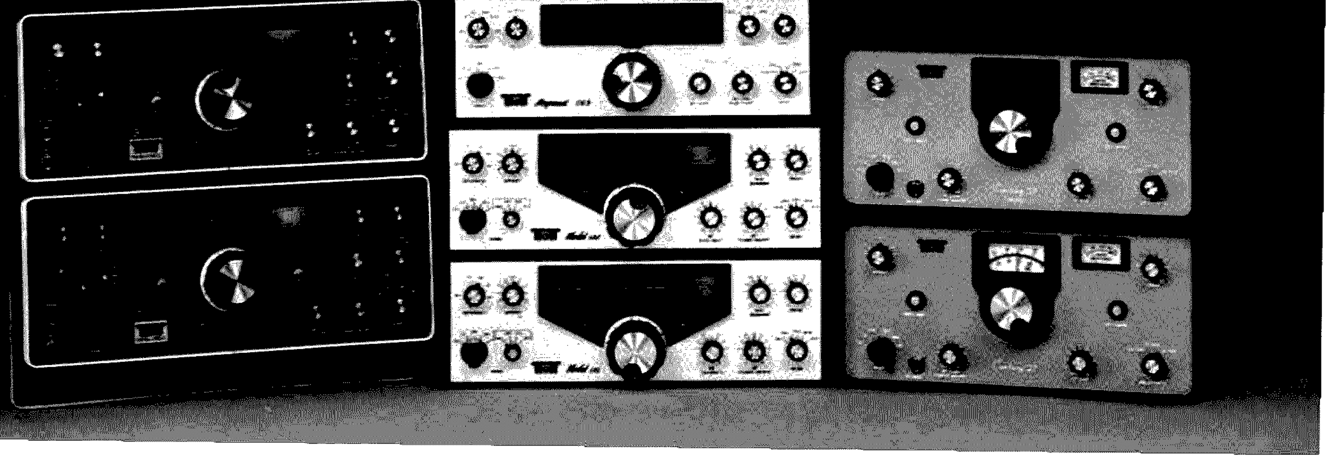
WIDEST CHOICE IN HF TRANSCEIVERS: TEN-TEC



The Ramsey 2m Amp Kit

—has a high Watts-per-dollar ratio

Compete with the big guns.

Tim Daniel N8RK
7 Peabody Drive
Oxford OH 45056

A few weeks of operating a Drake TR-22C convinced me that it was a good rig, but the 1½-Watt output just did not do the job. Unless you live next door to the repeater, your signal needs some kind of boost. For me, this booster had to meet the following requirements:

1) Low cost—leaving me enough money for another project.
2) Easy to construct—no tricky circuits or oddball parts.
3) Portability—usable at home, mobile, and in the field.
4) Adaptability—having other possible applications.

The portability requirement ruled out any antenna scheme. While an amplifier seemed to be the only option left, a quick check of the catalog file showed that such units are available, but the prices just didn't agree with my tight budget, and the fact that my workbench was already cluttered with several unfinished projects ruled out homebrewing.

One day, as I was scanning the ads in my favorite magazine (*73*, of course), I saw it: the Ramsey Electronics PA-1. It's a two meter power amp kit which features 8 Watts out for one in, and as much as thirty out for four Watts in. The best part was the price. At $22.95, it looked like a real bargain. It looked *too* good to be true, however, so instead of running out and buying it, I promptly forgot about it.

A few months later, at the Wheaton, Illinois, hamfest, the Ramsey people had a sample PA-1 on display. At first I thought it wouldn't work—it was just too simple. However, the reduced hamfest price got rid of any fears I had left, and I bought it.

The heart of the amplifier is a Motorola VHF power amplifier transistor. Its hefty construction convinced me it could easily handle the claimed thirty Watts if properly heatsinked. Class C operation is used, so. the unit is suitable for either CW or

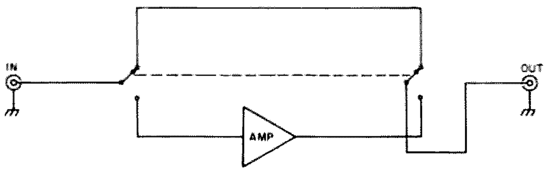


Fig. 1. A DPDT toggle switch or relay (see Fig. 2).

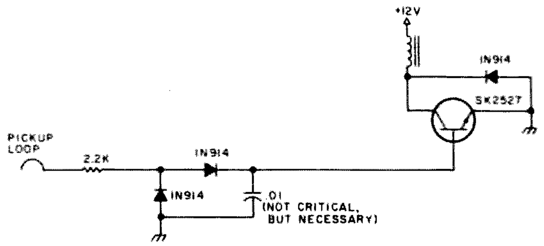

Fig. 2. Rf-sensing, relay-driver circuit.

FM operation. This also allows power consumption to drop to zero when receiving, so that battery life is extended in portable operation. Its wide input-to-output range makes it great for hooking up to rigs with different power output levels. Trimmer capacitors and a choke keep the unit running clean.

The instruction sheet takes only a few minutes to read. It is clear and to the point. Construction took me only two hours, but it could be done easily in half that time by a determined worker. The best part was the coil winding—it was over in less than five minutes. Soldering the transistor is the only critical step, and it is done last, so you have plenty of practice. I used plenty of heat-sink goop and made sure it was securely fastened to the chassis. The circuit board was the best I've seen in any kit; solder flowed on it with no problem. All parts were tack-soldered to one side of the board, so it helped to use plenty of heat.

Tune-up was as easy as construction. A wattmeter or some other measuring device is needed. The trimmers are adjusted for maximum output, and the amplifier is ready to go on the air. A check with a Bird wattmeter showed the amplifier output to be greater than nine Watts when driven by my TR-22C. The gain at that level is 8.9 dB, very close to the transistor spec-sheet 9-dB rating. Current drain was 1.2 Amperes, so efficiency was about 65%.

The kit comes with a circuit board and all the parts that go on it. No hardware, connectors, case, or switching circuitry are included. These can be obtained easily at an electronics supermarket if you don't already have them in your junk box. I bought a 5.25 x 3 x 2-inch aluminum minibox to house the circuit board and act as a heat sink. It is a bit larger than the board, so I have room for a receiver preamplifier or other additions at a later date. SO-239 connectors are mounted on either end of the box. I used the single-mounting-hole type, since they require less hardware and chassis work.

The instruction sheet includes a schematic for a T-R switching circuit. A DPDT relay is driven by a two-transistor sensing circuit. Since my junk box didn't have a relay that works on 12 volts, I decided to use a toggle switch instead. This simple approach, shown in Fig. 1, works well despite the inconvenience of having to flip a switch after every transmission. Later I was able to replace this cheapskate approach with a relay purchased from a surplus vendor. I simplified the suggested rf-sensing and relay-driver circuit by eliminating a transistor, two resistors, and a capacitor. A short length of hookup wire looped around the input line provides plenty of drive. The result, shown in Fig. 2, was wired on a small piece of perfboard which is glued to the relay case.

Someday my PA-1 will serve a second purpose as part of a simple exciter for OSCAR use. The PA-1 is one of several kits by Ramsey which I have built. All of them have met my expectations. The PA-1 has proven to be a real help in bringing up repeaters and in greatly improving my simplex range. Thanks to the PA-1, I can now compete with the big guns.■

An Improved Display for the TR-7400A

—very sensible

Simple, fast, effective!

The Kenwood TR-7400A 2 meter FM transceiver is a fine radio, but it can be improved, operationally speaking, by a simple modification.

This modification:

1. Eliminates out-of-band operation forever;
2. Provides instant monitoring of a repeater input frequency;
3. Costs nothing, requires no parts, and is easily restored.

To proceed, disconnect the power to the radio and remove the bottom cover. Looking at the large receiver board from the front, locate wire-wrap pin "TS" at the left front edge of the board near the relay. Remove the wire end from the pin by unwrapping. Now locate wire-wrap pin "RS" located at the right front of the board somewhat in from the right edge. Remove the wire from the pin by unwrapping. Slip this wire back through the cabling until it will reach pin "TS". Trim off excess bare wire and solder to pin "TS". Finally, splice about three inches of insulated wire to the remaining wire and solder to the "RS" pin.

Voilà! The "TX OFFSET" switch now becomes an "RX OFFSET" switch. The radio will now transmit only the frequency displayed on the LED readout (and the selector switches). No more accidental out-of-band transmitting when operating above 147.400 MHz! The "RX OFFSET" switch now affects only the receiver frequency and provides the +600 and −600 kilohertz offset function as marked. When working through a repeater, the operator may instantly check the input frequency by flipping the switch to "SIMPLEX" to see if the station being worked can be heard directly, indicating that a move to a simplex frequency would be in order. Simplex operation is the same as before modification.

As a final touch, a white decal letter "R" may be applied in place over the "T" above the offset switch and the caption "TRANSMITTER FREQUENCY" can be applied above the LED readout. Shouldn't all transceivers operate this way?

Credits to the Anaheim (CA) Amateur Radio Club and WB6ZFU for providing the information on the "RS" and "TS" functions.■

Inexpensive Scope Tuner

—"budget here is QRP, OM"

Build your own.

After I looked for a long time at the Heathkit SB-614 monitor scope and the Yaesu YO-100, I realized that I had no choice except to build my own tuner for my 3" general-purpose oscilloscope. Building the tuner according to the *Handbook* would cost too much here in Canada, and besides, it lacked the simplicity I wanted.

I built the tuner with parts I had on hand, so I hesitate to place any dollar values on them.

The balun was a kW 50-75 Ohm one. R1 is used to broaden the frequency response of the balun.

C1 and C2 can be changed to suit the power output.

The unit was tested with my Yaesu FT-101B on 10, 15, 20, 40, and 80 meters. Minimum meshing of the tuning capacitor, C2, was required on all bands.

Use RG-58/U or RG-59/U to connect the tuner to the scope.

It is important that the box is rf-leakproof! The Radio Shack metal cabinet I used has vent slots, and when I keyed the rig, my digital clock went into orbit!

My next project will be to reduce the size of the tuner and combine it with an swr bridge in one cabinet in order to eliminate the box and the coaxial jacks.■

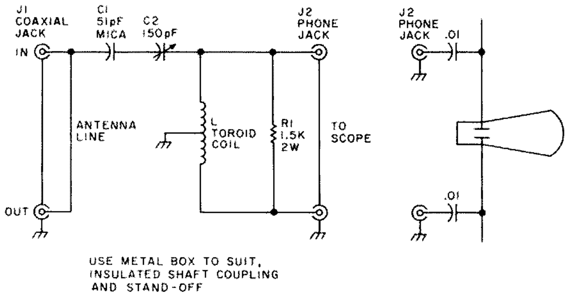

Fig. 1. Modification to a general-purpose oscilloscope to allow direct input to the vertical deflection plate. The capacitors are 1-kV discs.

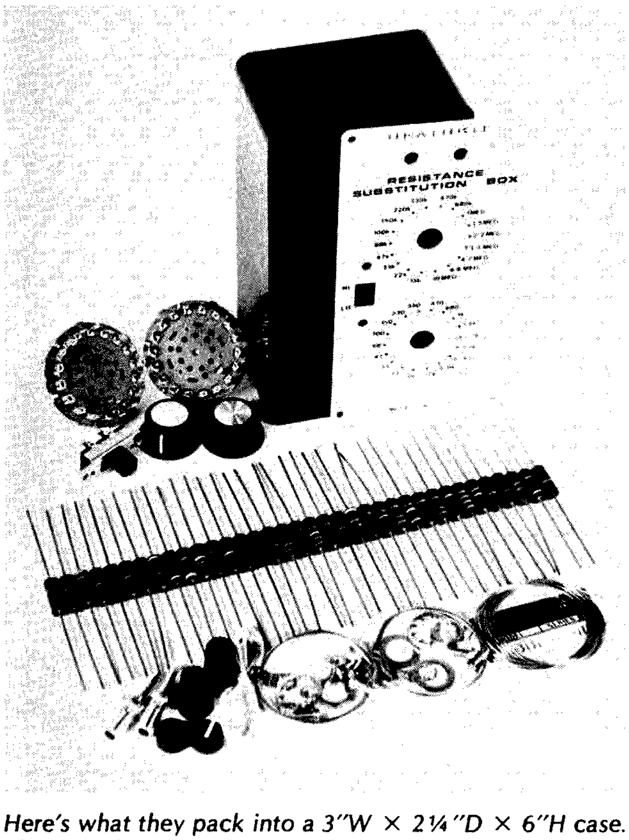
The Resistance Substitution Box

—a ham's forgotten friend

Does a lot for a little.



Here's what they pack into a 3"W × 2¼"D × 6"H case. These are husky parts, too, not flimsy.

In previous articles, I have been known to breezily advise readers to adjust a resistance value. If you are sitting there with a 100k, ¼-Watt carbon film resistor trying to figure out how to adjust it, you are probably thinking about getting me alone in a room for five minutes and adjusting me. That's not fair.

In self-defense, and to help solve the problem, I will tell you about one of the most useful pieces of test equipment and tools available to the experimenter or anyone who repairs equipment.

I have wanted to write this article for a long time, but I kept putting it off, trying to see if it couldn't be presented as a nice easy construction project which would save all sorts of money. What it kept coming down to was that I could save a few dollars rolling my own, but a reader might not be able to duplicate it easily, and the few bucks wasn't worth the irritation.

The tool is a resistance substitution box. A kit version represents one of the best dollar values around. The price for the whole kit is so close to what the parts would cost that it actually represents a greater value. Everything is done for you. You just have to put it together. That's getting most of the hand labor almost free.

I bought the Heathkit model IN-3137 in kit form. The first thing you notice is that you get a husky handful of parts. In spite of the relatively small price, this is a meaty kit.

The Heath instructions are well known and there were only a few sticky places not really pointed out. They are in the area of general construction hints.

When mounting the two binding posts, it helps to put a small nail or something through the little hole so you have a handle to hold the hole in position when you tighten the mounting nut. This way the pieces will be lined up the way you want them rather than just randomly as they happen to hold.

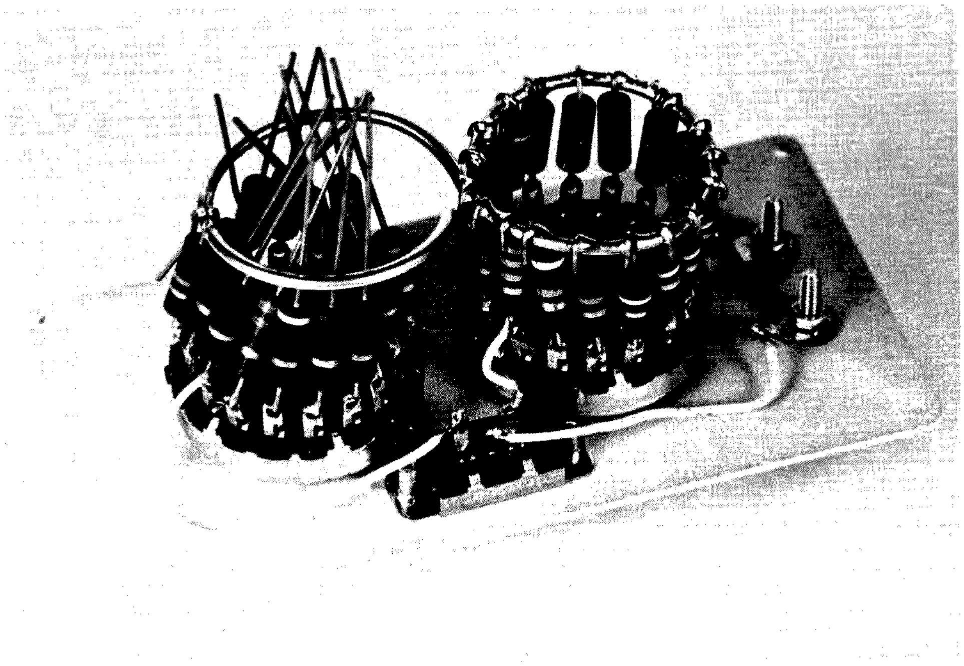
The only fussy job in the kit is soldering the mounting ring that holds the ground end of all the resistors. This shows in the photo. It just takes a little care and forethought. You want to have the resistors mounted evenly and the ring at the correct height so that the finished assembly will fit in the case.

Do the first resistor at the right height as per the instructions, and then choose a resistor at the other end of the ring and do it. If you space about four resistors around the ring, it will let you set the ring at the correct height easily and make a fairly rigid assembly to mount the other resistors to without worrying about the lead length. I did not think of this until after I did the soldering of each resistor in order, so mine looks a bit lopsided.

There really were no problems putting the kit together, and I could only fault it slightly in a few areas.

I would have liked to have color-coded binding posts—one red, one black—to tell which one went to the big lump of metal. It can be marked on the case.

It would have been nice to have a couple of color-coded insulated clip leads supplied. With all the test gear hooked up for testing, that's one thing you may be shy of when you go to use the box. It doesn't cost much to make your own, but you won't think of it until you are working and need them NOW.



The only sticky part is mounting this S-ring full of resistors. The text gives some hints.

There are a few other construction hints to keep in mind. As you put it together, remember that you may have to take it apart.

Unless you just plan to look at it on the bench, you will probably fry a few resistors along the way like the rest of us. They will have to be replaced. Don't wire them in for the ages.

It may still seem a bit exorbitant to spend that much for a box of resistors and a few switches. I got along without one for a while, but, once I had one, I did not want to do without it.

Years ago, I would use clip leads and wire in a resistor near what I wanted from the junk box. I had an assortment of values, none too complete, but it did work. The problem was that it was clumsy and it took far too much time. Also, the box is a lot more precise than you might think.

In Fig. 1, the problem is to determine the resistance value to allow only so much current to the LED. From looking at circuits, you have some idea of the current range most LED circuits take.

Let's fill in some more. You don't know what the junk-box LED is rated at, so you want to go easy. You can tell a bit from the way it lights, assuming you don't blow it right off the bat.

Hook up the VOM to read milliamperes (low range) and the box in place of R1. Start at a high value of resistance—in this case 10k. You might as well get into the habit of starting at the very top. Slowly click your way down range. Watch the meter and the LED carefully. At some point, the LED will just start to light and the meter start to read.

Most LEDs can handle about 10 mils or so. As you watch the LED, watch the meter. The LED will probably light dimly at first and get brighter as you lower the resistance and increase the current.

You may reach a point where an increase in current only makes a slight increase in actual brightness. This is about the maximum current point. For the best results, increase the resistance a notch or so until the LED starts to drop off the other way. Somewhere in that range is where you want to be. Not dim, but not the brightest it will go. That 10-mA figure is a good target for an unknown LED.

This is the best working range for the LED. If you have to save current—perhaps you are running a lot of LEDs from a battery—you might even want a dim light and a smaller current. Here, current would be the main factor.

The point is that, using individual resistors and clip leads, you would have only had time to try one or two in the time it took to read this. Using the box, you would probably have completed the job in that much time and in a far more controlled and safe manner.

Let's take another job. You are working in an audio section. You have a

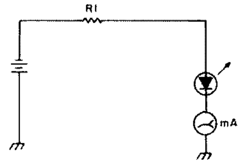


Fig. 1.

dead triode amplifier stage. You look in and find that the plate load resistor is fried to a crispy color. What was it?

You can get a hint from similar circuits or maybe what else is in the set, but, if you want to get it going fast, it's easy.

First check for other damage, like a shorted bypass capacitor that caused the resistor to draw too much current, or any other trouble in the circuit which should be corrected before replacing parts (you don't want to burn up the replacement resistor, particularly the one in your substitution box).

Clip the box into the circuit set at its highest value. Then click down as you monitor the stage. If nothing else is wrong with the stage, it should click in at some point. Play around and choose the best value for operation, then replace the box with the fixed value.

Of course, you can see how handy the box would be for experimental purposes if you were designing a stage. It makes it a breeze to try values and evaluate performance quickly. The nice thing is, the box will work just as well with tube or transistor circuits. The one-Watt values are good for most tube circuits and a higher percentage of transistor work.

The one way you can immediately damage it is to send too much current through one of the resistors. The use of a milliammeter is recommended. Also, the switch is rated at only 500 volts.

A little common sense about what you hook it to can help, too. Before you start clicking, use your pocket calculator to figure Ohm's Law for a few of the values and see what the current and power would be.

The completed box has a nice husky feel to it and won't get lost on your bench.

Most of the time, a little thought will keep you on the safe side of the power ratings. Once in a while, you may hit the box too hard. Get out the iron and welcome to the club.

There is one big thing to watch for. If the circuit calls for a power job, or you see one in there already, keep the box out of there. Even for a short test, it's risky.

Sooner or later you will put too much current through one or more of the resistors. This happens to everybody. It is the fate of the experimenter. A little bit of preventive care and knowledge will go a long way toward helping you over this problem. Besides care in construction, you should have a bit more detailed knowledge of what's in there.

When you build, or buy, your RC box, hook up your best ohmmeter to it. I hope that you have something that is fairly accurate.

I keep a few 1% resistors handy to check mine with. It doesn't have to be a lab meter. Mine is rated a nominal 3%. The box resistors are within 10%.

Go through the whole range of resistances and write down what they all measure when the box is new. File the information with the book that came with it. Then it's easy to go back and check it every now and then or when you think you might have fried something. You will have a known set of standards to compare with.

When you make the chart, do not fuss if they do not seem to be exactly right on the nose. They are only supposed to be within 10%. At 100k, you could read 90k to 110k Ohms.

If you have it wired correctly, they should all be within tolerance. You might possibly have one or two out. It could be a faulty resistor, or maybe it got too much heat. If you have more than that, you had better check your meter out with a friend's before complaining.

To repair the box, just measure the values and replace the ones that got out of tolerance. You can assume that they will age and they will get some current once in a while.

While the values seem far apart when compared to the chart of available resistor values, they are effectively within range of each other. The in-between values will make a difference in actual circuit operation, but the box values will make what might be called a significant difference. It's big enough that the difference will be noticeable, but not so much that it doesn't have a safety margin. With care, you should have plenty of notice that you are getting near a danger point of operation.

While it won't do your fine pruning, it will put you in the range you want to be and should give you an operative circuit value.

One obvious question is, what about all those 1% transistor circuits you seem to have to work with? Well, they would be a problem no matter what you were using. The basic problem is that there really is no such thing as a 1% circuit in electronics. It may be that when it rolls off the assembly line (most aren't), but give it a while and it will be out of tolerance.

For most uses, you have no business making a circuit that is that critical. Most tube and transistor circuits are nominally within ten percent when new.

After regular use, most circuits I've worked with were within 20%. Most

well-designed circuits will work with parts values ±50%.

Often an out-of-tolerance circuit will work just fine and not be the trouble you are looking for. You may also have the problem that it would cost too much to go through the entire equipment and bring everything up to tolerance.

With precision equipment, this is not desirable, but there comes a point where it costs too much. In this case, you don't have to worry so much about tolerance. Does one of the values work? Put in a precision replacement.

If you are designing your own equipment, aim for noncritical design and standard parts values. That little bit of theoretical advantage in optimizing can be quickly offset by normal aging and servicing problems.

Another thing. If you are trying a range of values and the circuit is critical as to value, it may be a strong indication that its design is wrong.

Most functions can be performed by noncritical circuitry. The added stability to be gained thereby can be quite valuable.

Save the critical circuits for where you need them. Even then, it pays to use common sense about values. Is it something you are going to be able to get a replacement for in X amount of time? That's something to think about.

If you repair your own equipment, or if you like to bench-design your own gear, the resistance substitution box is a hard piece of equipment to beat. For the job, its speed, versatility, and low cost make it a real test and tool bargain. ■

Vodka Amongst the Penguins

—hamming with the Russians in Antarctica

Mirnyy, 1961.

"Stew, how would you like to go to Antarctica for a year with the Russians?" Professor Bob Helliwell asked me one morning at Stanford University, California, in November, 1960.

"Sure," I said, "when do I go?"

"Well," said Helliwell, "you'll leave right away. That is, *if* you get the job!"

He explained that the National Bureau of Standards at Boulder, Colorado, under a National Science Foundation grant, was sponsoring a US exchange scientist to go with the sixth Soviet Antarctic expedition to Mirnyy Base, Antarctica. They were interviewing several people at Boulder right then.

"Something happened to the original candidate, and his replacement must be chosen and must leave for Antarctica immediately," Helliwell said. "The candidate will meet the Soviet expedition ship in Capetown if he can get there in time, and the ship has already left Leningrad!"

I was hoping to finish my E. E. degree in a couple of months. I had taken one leave from school already, to work in the Azores Islands and also to study at Edinburgh, Scotland, but this chance was too good to miss. Bob Helliwell knew I was interested in Antarctica, since he was a Scoutmaster and remembered that I had narrowly missed being chosen as the Boy Scout to accompany the USIGY Antarctic Expedition. Also, I was familiar with the research work proposed by the National Bureau of Standards, since I had operated similar equipment during summers when I had worked for the Stanford Research Institute.

Photo A. The diesel ship OB *is wedged in sea ice near Mirnyy, Antarctica.*

Well, I was lucky enough to get the job. I was briefed quickly at NBS and at the National Science Foundation in Washington. I then left New York City in a DC-7 bound for Capetown, accompanied by crates of gear weighing over 12,000 lbs. In Capetown, I met the Soviet ice cargo freighter *OB* (named for a large river in Siberia) and proceeded to Antarctica, where I spent the next 13 months at Mirnyy, the Soviet's largest base. (See Photo A.)

Not only did I do radio-

physics research and meet and get to know many Soviet colleagues, but I also became one of the operators of UA1KAE, which was for some years Antarctica's only active Soviet ham radio station. During my interesting time with the Soviets, I traveled to numerous locations in the Antarctic. These included the Soviet Vostok station at the southern geomagnetic pole, where the world record for minimum temperature was set (−126.9° F., recorded in August, 1960), and the US station at the geographic South Pole.

I spent most of my time at Mirnyy station, located at about 93° E, 67° S, on the coast of eastern Antarctica. (See Photo B.) Mirnyy is situated on continental ice anchored by underlying rock formations near the sea. There is a dangerously steep 50-foot cliff overlooking the sea to the north; two hills protrude from the ice. UA1KAE, the ham station, and the rest of the radio transmitting equipment (shown in Photo C) are located on one of these hills—"Sopka Radio," which means Radio Hill. Mirnyy had a population of about 100 persons in the winter, including 20 assorted geophysicists and meteorologists. (See Photo D.) Most of us lived in separate buildings having from 3 to 12 occupants each, and, when weather permitted, we traveled along "Lenin Avenue" (see Photo E) to a central dining hall for meals, meetings and movies.

My main purpose in going to the Antarctic, besides serving as a guest and exchange scientist with the Russians, was to initiate a program of cosmic radio noise measurements in the Antarctic. To make these radio noise measurements, I brought along two Riometers. The Riometer was first designed to study auroral radio-wave absorption in Alaska, and the name was coined from *R*elative-*I*onospheric-*O*pacity meter. The instrument itself was based on noise-measuring gear developed for radio astronomy. But whereas a radio astronomer would use such a receiver to measure galactic radio noise, I would use stellar radio noise as a signal source to measure the *absorption* of this noise at HF in the ionosphere. The absorption I measured is caused by, or associated with, solar storms, aurorae, and other geophysical events.

Study of the upper ionized layers of the Earth's atmosphere, both from ground level and from rockets and satellites, is important not only for increased knowledge of plasma physics, wave propagation, and geophysics, but also it contributes to our daily efficient use of the radio spectrum for telecommunications. Back in 1925, Merle Tuve and Gregory Breit, at the Carnegie Institution's Department of Terrestrial Magnetism in Washington DC, first studied the ionosphere vertically using a pulsed, vertical-sounding transmitter and receiver—a crude radar. This technique was further developed during the 1930s and during World War II, and the standard instrument which evolved came to be known as the Ionosonde.

This device, often using a delta or half-rhombic antenna aimed at the zenith, sends pulses skyward over a broad range of frequencies from 2 to about 25 MHz. The reflected signals received at the ground allow one to measure the "height" of the ionospheric layers and the electron density at the peak of the reflecting layers. This type of approach has been used even in the polar areas for many years.

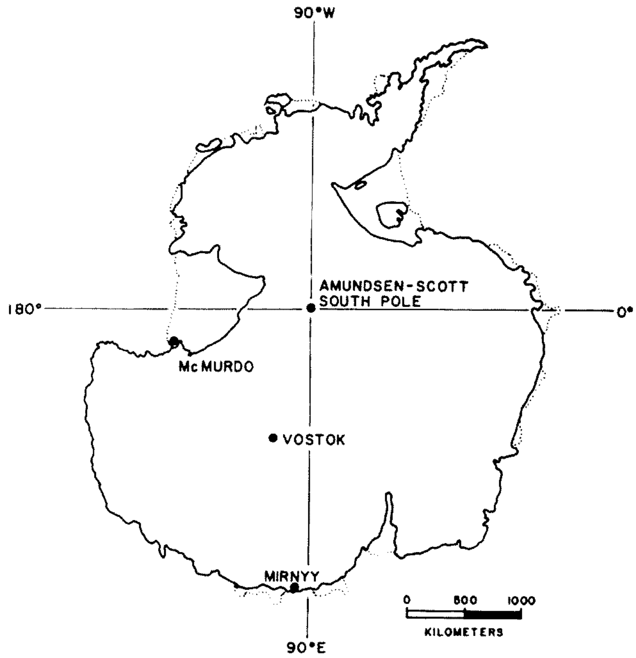

Photo B. This is a picture of a map of Antarctica which was drafted by the author's wife. It shows the location of the four stations.

Lt. Malcolm P. Hanson, of the US Naval Research Laboratory, constructed equipment and made the first such polar measurements while on Byrd's first Antarctic expedition, in 1929-30. Edward V. Appleton, who won the Nobel Prize in physics in 1947 for his ionosphere researches, utilized similar equipment in northern Norway during the 2nd International Polar Year in 1932-33. (The general history of radio research in Antarctica is covered in my essay, "Early History of Upper Atmospheric Physics Research in Antarctica," L. J. Lanzerotti and C. G. Park, editors, in *Upper Atmosphere Research in Antarctica*, American Geophysical Union, Washington DC, 1978.)

The Ionosonde has definite limits to its use in polar regions: The man-made signals have to pass through the ionosphere twice, being absorbed on

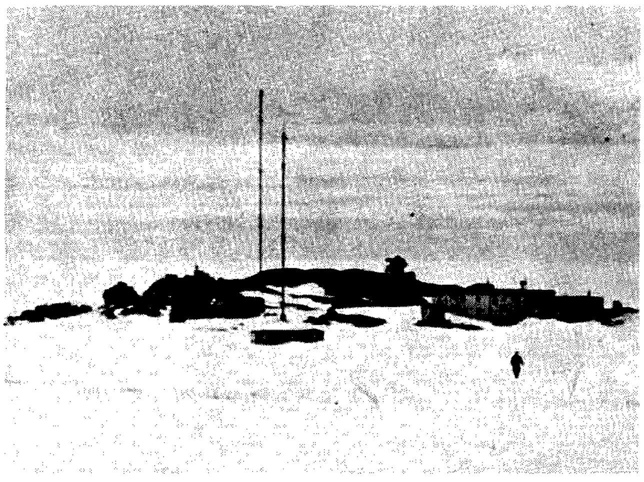

Photo C. "Sopka Radio" (Radio Hill), where the Mirnyy transmitters and UA1KAE were located.

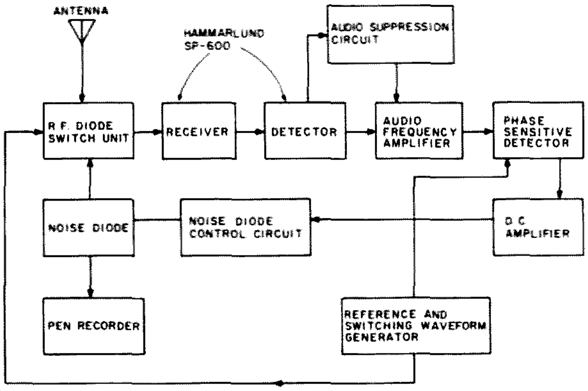

Fig. 1. Block diagram of Riometer.

passing up from the ground and then absorbed again upon returning down towards the receiver. During active auroral events or after solar storms, the absorption of radio waves at MF and HF is frequently so high that no signal is received on the ground, and the ionosphere is said to be in "blackout" condition. It is so-called because the Ionosonde record shows no evidence of returning pulses.

It is just *during* these events, however, that so much of importance happens in radiophysics. C. G. Little and H. Leinbach, the designers of the Riometer (*Proceedings, I. R. E., 47*, p. 315, 1959), realized that if a signal source could be placed outside the Earth's ionosphere, the signal would suffer much less absorption. The device could then report continuously, even during total radio communications blackouts. In addition, the Riometer could measure absorption at frequencies as high as 50, or even 150 MHz, where no vertical pulses under normal conditions would be reflected from the ionosphere.

Of the two Riometers I brought with me, one was for use at 30 MHz as the primary unit and the other was a backup unit which could also be used at 50 MHz. (See Photo F.) Ionospheric absorption usually varies as the inverse square of the frequency; thus the 50-MHz unit could be expected to measure $(30/50)^2$, or about 0.36 as much absorption as the 30-MHz unit. The Riometer needed as its heart a good receiver. We chose the Hammarlund SP-600, since it was capable of operating with a bandwidth of about 13 kHz and covered the HF bands up through 6 meters, thus allowing me to operate either unit on 30 or on 50 MHz.

Photo D. A cold and windy "May Day," 1961, at Mirnyy; the author is third from the left. The power lines are from diesel-powered electric generators and run to the buildings where heat coils feed hot water radiator systems.

Basically, the Riometer is a servo-controlled, self-balancing receiving system designed to measure ionospheric absorption by monitoring "cosmic noise." The block diagram of an early version is shown in Fig. 1. Reference to this diagram will facilitate interpretation of the following description.

The diode switch unit switches between the antenna and the servo noise diode at an audio rate. The resulting signal is fed into a low-noise receiver (the SP-600) whose detected output consists of alternated noise from the antenna and from the servo noise diode. If the two inputs are balanced, the detector output looks like an audio square wave.

The receiver-detector output is fed through an audio suppression circuit and an audio amplifier into a phase-sensitive detector. (The audio suppression circuit breaks the servo loop when a strong interfering signal is present.) The dc output of the phase-sensitive detector depends in amplitude and sign on the unbalance between the noise-diode signal and the antenna signal. The output of the phase-sensitive detector is fed to a dc amplifier whose output constitutes the input signal to the noise-diode control circuit, which functions in such a manner as to bring the noise output of the servo noise diode into equality with the noise signal power from the antenna.

The plate current of the servo noise diode is directly proportional to the input power of the antenna signal and is recorded on a pen recorder. Additional refinements, such as sweeping the local oscillator of the receiver through 100 kHz and using a minimum signal detector, serve to minimize the effects of interference on the Riometer. Solid-state Riometers having digital output and automatic data processing are now in use, but my vacuum tube units at Mirnyy in 1961 were quite similar to the original design of Little and Leinbach. They required daily calibration and adjustment.

The Riometer was a big improvement over merely measuring receiver noise power, since the noise-diode current could be carefully measured each day and receiver-gain changes with tube aging had only a minor effect on the system. We wanted results accurate to one- or two-tenths of a dB over periods of a year. I had a very fancy ac-powered pen recorder, but I found the 50-Hz power at Mirnyy varied by several Hz throughout the day, so I went back to using two old standard spring-wound Esterline-Angus pen recorders which I could adjust to record with an accuracy of about plus or minus a couple of minutes a day.

In addition to the Riometers, I had assorted test gear: two Hewlett-Packard 'scopes, an rf bridge and signal generator, an H-P VTVM, and a Hickok tube-tester. I also had the loan of a fine Collins 51J4 receiver, courtesy of Mike Villard W6QYT of Stanford University. With this, I hoped to monitor shortwave-broadcast-station signal strengths after solar storm events and also try to listen for around-the-world echoes (and maybe long-delay echoes) from Villard's experimental transmissions on 21 MHz. I

never heard any long-delay echoes, but in free hours I did get quite a bit of pleasure from monitoring baseball and football games broadcast over Armed Forces Radio, and I often caught Willis Conover's Voice of America Jazz Show.

For a student research project at Stanford, I had constructed a large, 84-element, 4-boom log periodic antenna array on a rotating 60-foot tower, combined with a 25-to-35-MHz sweep-frequency receiving system for solar and planetary radio astronomy investigations (see *Electrical Engineering, 81*, p. 22, 1962). Of course, I couldn't bring the LPA array with me, but I did bring the receiving system. I hoped to erect a rhombic antenna and continue my measurements at Mirnyy. Although I made a few measurements, my first priority was to the Riometer work, and I didn't do much with the sweep-frequency radio astronomy gear.

In addition to the above, I also brought with me an Ampex tape recorder and a small solid-state (remember, we called them "transistorized" in those days) Develco audio amplifier and loop antenna to record geophysical noises in the VLF range from about 100 Hz to 10 kHz. Bob Helliwell had loaned this equipment to me. VLF recording was becoming of great importance to upper atmospheric and space physics research. Today, VLF research has assumed even greater importance for plasma geophysics *and* telecommunications research. Lightning strokes and other natural phenomena sometimes propagate as radio frequency energy along magnetic field lines from one end of the Earth out thousands of miles and then re-enter the atmosphere at the other end of the field line.

Each different frequency—say, of the lightning stroke—propagates with a different velocity, so that a pulse which sounds initially like a "click" near the source may sound like a long whistle, decreasing in pitch, at the other end of the Earth. As it turned out, a Czech visiting scientist had recorded "whistler" and VLF activity at Mirnyy station for some months before my arrival. Thus I sent the whistler gear on to Vostok station, a unique location with *geomagnetic* coordinates near 90° S—something like Thule, Greenland, in the north. No one then knew what sort of whistler activity would be heard at Vostok, since it was at such a high geomagnetic latitude.

Although modern VLF work in the Antarctic dates from the late 1950s, VLF work in the polar regions was initiated on Byrd's 2nd Antarctic expedition in 1933-34 by John Dyer (now W1BJD). In those days, there were hopes of connecting "whistlers" with meteor sightings. Dyer never published his fascinating VLF observations, but correctly he noted no correlation between whistlers and meteors. My VLF measurements had only limited success, but my Riometer results were first in what has been a continuous and growing use of this radio wave-absorption measuring technique in Antarctica.

When I first arrived at Mirnyy, I wished I had brought an HF transmitter with me for ham radio purposes. I had been licensed first in 1953 as WNØODE, as a high-school freshman in Grandview, Missouri, and I had kept somewhat active as WØODE and at the Stanford student station, W6YX. Looking through my stock of vacuum tubes, I figured that I could build a CW transmitter using a 12AU7 or 6AH6 as a vfo, a 6AG7 driver, and push-pull 6L6s running 75 Watts on 40, 20, and 15 meters. I knew I wouldn't have time to do any rig-building for several months, since we all had so much work to do to get the general aspects of the expedition in order and to get the various scientific experiments working.

For example, the anten-

Photo E. This is "Lenin Avenue," the main drag at Mirnyy. The picture is taken from Radio Hill looking north to the other rocky hill, which is at the edge of the sea ice.

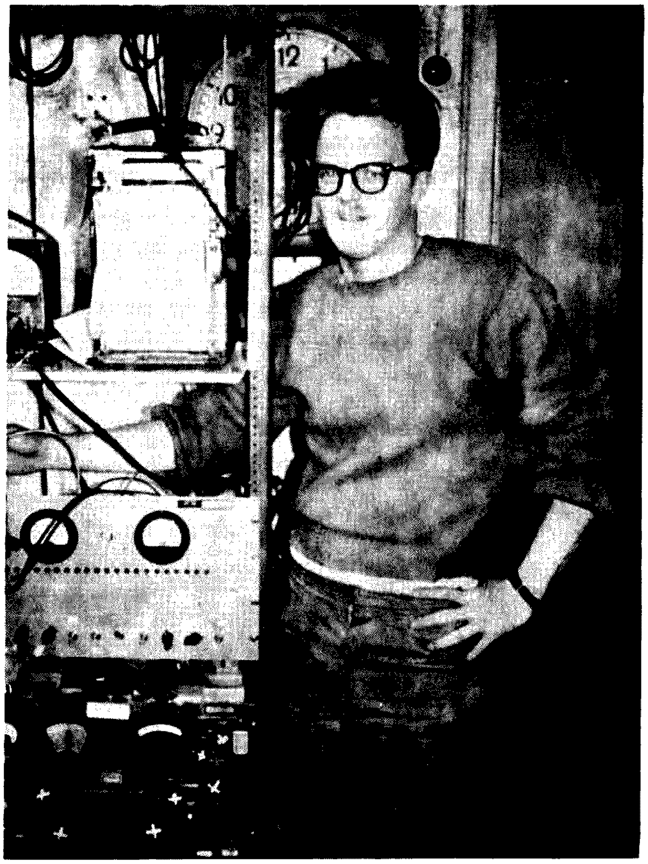

Photo F. The author is standing beside the 30-MHz and 50-MHz Riometers. Also shown are the power supplies, Esterline-Angus chart recorders, test gear, and Hammarlund SP-600 receivers.

nas for my Riometers—see Photo G—were broadband, 4-element yagis—that is, two driven elements, each over a reflector, phased so that the beamwidth would be approximately circular. These elements were of aluminum pipe approximately 3 inches in diameter, placed around very heavy fiberglass poles. Erecting this array took quite a bit of time. Because of local conditions, I eventually replaced this rather elegant design with a simple wire dipole placed over a metal roof as the reflector.

Well, I mused over my proposed 6L6 rig and wrote a letter to the FCC to be mailed to them when the Soviet ship *OB* left the Antarctic to return to Leningrad. I wondered whether or not I should operate as WØODE/KC4. I was on a continent not claimed by the US (or by the USSR, for that matter), and I was not on a US expedition.

In the meantime, I got a chance to visit the radio communications center at the base. This building had a small studio room for broadcasting to Moscow, a room for Teletype™ equipment, and a general operating room containing tape recorders and several MF, HF, and VHF receivers. I learned that the military HF receivers used at Mirnyy covered 1.5 to 25.5 MHz. The transmitters, however, were not in the communications center but were located on Radio Hill, about a half mile away. This was done in an attempt to lessen local QRM when the station was operating simultaneously on several frequencies.

Quite soon thereafter, I wandered up to the transmitter building and spent about an hour listening on 20 meters. I heard good signals from South America and also from several strong ham stations in the US. I also heard KC4USV at McMurdo Sound, Antarctica.

I was told that the transmitter building was, in fact, the location of ham station UA1KAE. (See Photo H.) KAE signified *A*ntarctic *K*ontinental *E*xpedition; the UA1 indicated that the expedition's home base was Leningrad. I was told also that I could be one of the operators of UA1KAE. The station didn't operate during the austral summer since everyone was too busy, but as soon as Antarctic autumn came around in March, I began to go up to the ham station once or twice a week, when weather conditions permitted. We had several transmitters at Mirnyy, some of 5 kW and one or two of 1-to-2k-W input. It was one of these latter transmitters, usually with dipole antennas, that was used for hamming.

UA1KAE had averaged about 1500 QSOs per year since it had been set up in 1957. The transmitter was not capable of SSB operation. I attempted to operate AM, but the rig didn't seem capable of much modulation, so my contacts were nearly all CW, at least one-way. I usually worked 20 meters, although I did get on 15 and 40 meters. I didn't operate UA1KAE as often as I might have wished due to my own work schedule and also due to our weather. It doesn't get very cold at Mirnyy. Unlike Vostok, which regularly runs at about −100° F. in winter, Mirnyy rarely gets below −40° F. On the other hand, Mirnyy has a heck of a wind-chill factor!

Mirnyy is located on the east coast of Antarctica, where the world's worst storms occur. The cold inland bases have no wind to speak of during really cold periods, but winds come down off the 10,000- to 13,000-foot plateaus of east Antarctica, meet much warmer winds off the Indian Ocean, and all hell breaks loose. One time, winds broke two ¾-inch steel cables holding down one of our IL-2 aircraft (a Russian version of the DC-3). The plane took off by itself under wind power and flew about 3 miles out over the sea ice before crashing into an iceberg! Many, many days the weather was such that we could not venture outside and go the 150 yards to the dining hall, or, if we could, we had to go in teams along rope-guided paths. Thus, the ½-mile trip to Radio Hill through drifts, in blizzard conditions, forced me to cancel a number of my hamming sessions at UA1KAE.

Photo G. The author is erecting an antenna element.

One amusing thing often happened when I operated CW. UA1KAE was celebrated throughout the USSR, and there often would be Soviet ham stations piling up to work UA1KAE. In those days I did not know the Cyrillic alphabet in code (there are several extra letters such as: ya = ·—·—; ch = ———·; sh = ————; etc.). The Soviet stations, naturally, would swing into Cyrillic. I would then come back in badly *transliterated* Russian saying, "I do not write Cyrillic; I am an American operator of UA1KAE." Invariably, the Soviet operator then cut off his transmissions. I suppose at the least he thought I was a pirate station.

I did have a few CW-SSB QSOs with American hams. These were in attempts to talk with my parents in Kansas City, Missouri, and with some of my university friends in Palo Alto, California. Other hams passed traffic for me through the ham stations at McMurdo and other US

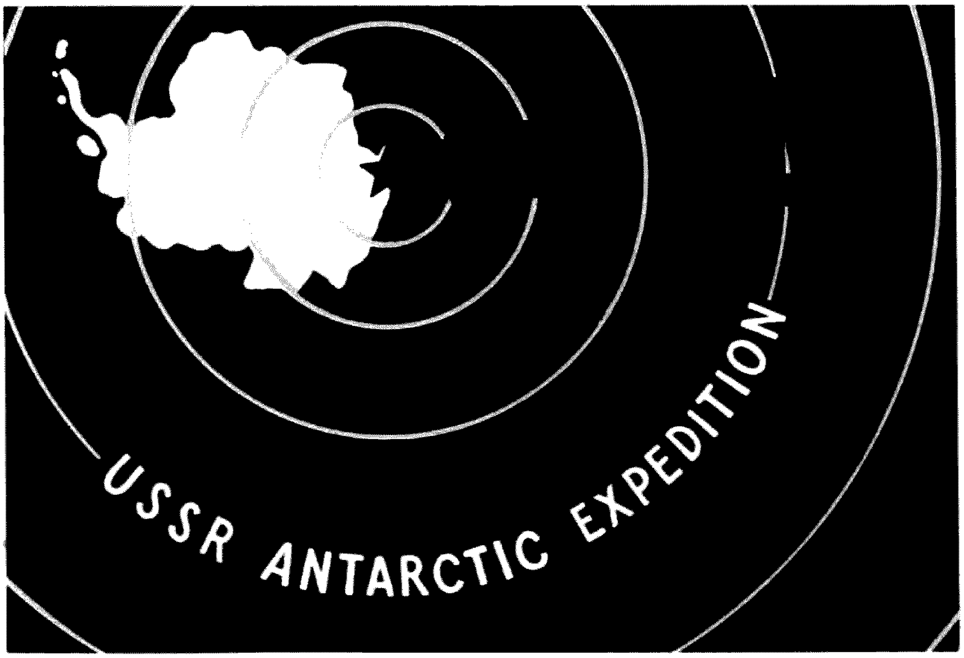

Photo H. This is the UA1KAE QSL card. The star marks Mirnyy's location.

stations; these hamgrams were then sent to me via Navy circuits from McMurdo to Mirnyy. Hams (some, regretfully, now silent keys), or calls I remember with gratitude, include Mike WØMAF, Fred W6QS, Jules K2KGJ, WØRDR, WØMM, and Lee Bergren.

I had also another quite different but amusing incident involving CW. I was asked to help get a RTTY link going between Mirnyy and McMurdo stations. We had tried for some days without success and also had had difficulty raising McMurdo on CW. I suggested that I could try McMurdo on the ham bands, and the chief radio engineer at Mirnyy agreed that it was worth the effort, so I went up to the transmitter building and listened on 20 meters sideband. Sure enough, there was KC4USV, big as life.

Now, it happened in those days (just as it does today) that ham tickets were issued at Antarctic stations to men who supposedly had qualified in the Antarctic and were given Conditional class licenses. I am pretty sure that some of those license exams were a sham. I tried to break KC4USV's stateside SSB QSO via my own CW. I tried several times, slowing my CW to well under 13 wpm. The US ham called the KC4USV op's attention to my break call, but the KC4USV op mumbled something about not being able to copy it and refused to let me break in.

A couple of days later, when communications were re-established, I sent a short comment to one of the regular Navy CW ops to the effect that at least one of the KC4USV ops had better take some of the grease out of his jaw and begin applying it to his elbow. The Navy CW op agreed with me. Little did I know that the McMurdo communications officer in charge (a) knew virtually nothing about radio, (b) was one of those individuals who had been "given" Conditional tickets, (c) was the guy at the microphone at KC4USV the day I had tried repeatedly to break in on CW, and (d) read my brief radiogram describing his performance!

That incident was almost as funny as the time a US biologist at McMurdo had a fit when I told him over the radio that the "rare" white-blooded fishes we had caught in a Mirnyy fishing contest had been eaten by us right after the event. Boy, he howled about the principles of the scientific life, the duties of the scientist and so forth, when all he really wanted was for me to haul back some fish in formaldehyde so that he could publish a paper. I told him, truthfully, that we had no formaldehyde at Mirnyy and that we had already drunk all the vodka and grain alcohol! Actually, the fish were fried up and were pretty good, tasting like perch. Penguin eggs, on the other hand, were terrible, tasting and smelling like rotten fish. (See Photo I of my friend "Little Vasily" and I trying to consume a penguin egg omelet.)

By the way, we didn't kill any birds or eat living penguin eggs at Mirnyy; the eggs we ate had been blown away from the Emperor penguin rookery in a storm and had frozen.

My Soviet friends made up in ingenuity for what they lacked in parts and supplies. While we did some rather hazardous things on aircraft flights (such as cooking lunch in flight on an open-flame burner, quite near barrels of aviation gasoline), they had a good air-safety record. Unfortunately, their fire-safety record at Mirnyy wasn't so good. Fire is a deadly enemy in the Antarctic since there is virtually no water available to fight it. Eight meteorologists were lost at Mirnyy in a fire just 4 months before I arrived.

Similarly, the Soviet communications equipment was boat anchor stuff which seemed to work pretty well. Even so, two old 1940s-vintage RCA receivers were incorporated into gear in use at Mirnyy. I assume that these were old lend-lease receivers from World War II. I had a 1960 RCA Semiconductor Handbook with me, and the electronics people were amazed and almost incredulous at the relatively large number of transistors which were then available to industry and to hams. To prove my point, I had at least the Develco VLF receiver to show for solid-state gear. NSB had already constructed solid-state Riometers, but I could not take them to Antarctica because they had not yet been through the required six months of laboratory shakedown.

Other items of great interest were my stereo music tapes, lightweight nylon clothing, Missouri corncob pipes, my Polaroid camera, and, of course, various men's picture magazines.

On my part, I found quite fascinating the Soviet's leather and fur clothing, their language, the great similarities I found between American and Soviet humor, and the way Americans and Soviets

Photo I. The author and his friend, "Little Vasily" Nikonov, a meteorologist technician, attempting to eat the terrible-tasting omelet made from Emperor penguin eggs.

Photo J. Mirnyy staff members celebrate the author's birthday, November 6, 1961.

view the world and react to numerous situations. (See Photo J.) Most of all, I found the Antarctic itself intriguing, subtle, and forbidding.

Lots of things have changed since I spent 13 months as a guest with the Soviets 18 years ago. It's much more common now to see flights in and out of Antarctica. As everywhere else, computers, microelectronics, and satellites have altered equipment, methods used, and research questions asked in the Antarctic. Mirnyy is no longer the main Soviet base, and even the Soviet ham calls have changed—being things like 4K1A instead of the old UA1KAE. But all in all, it was a great experience for me, and I recall many events fondly.

Finally, I must confess I have probably set a record or near-record for poor QSLing. In going through some old boxes last year, I found some 17-year-old QSL cards from UA1KAE for contacts I made. These had gotten mislaid in shipping my baggage out of the Antarctic in 1962. To those of you who have recently received 1961 QSO confirmation from UA1KAE postmarked 1978—sorry, fellows! ■

Note: My thanks to my wife, R. G. Gillmor, for drawing the map of Antarctica, and to A. Bothell for help with photo reproduction.

Protect Yourself with a GFI

—before it's too late

Make your hamming safer.

C. C. Lo WA6PEC
5414 Barrett Ave.
El Cerrito CA 94530

The ground fault interrupter (GFI) has been around for some time. Like many other safety devices, its popularity grows slowly because safety devices are not favored, as a rule. For an amateur radio operator, however, the GFI could be very valuable because a ham comes in contact with lots of line-operated equipment, and, inadvertently, some faulty equipment could turn up and shock the daylights out of him.

The GFI described here will prevent a normal person from suffering severe shocks by turning off the line power in approximately 25 ms when a fault current as low as 5 mA is detected. While 5 mA of 60 Hz current will cause some sensation, a persistent 10-20 mA could cause fibrillation of the heart and breathing to stop. The GFI can be built for 110 V or 220 V operation; load current capacity is rated at 25 Amps.

How It Works

Refer to Fig. 1. The heart of the system is a differential transformer, T1, which senses an imbalance load current on the two power lines which are wound on the toroid core in a bifilar fashion. Differential current as low as 5 mA will produce a large enough signal to change the output state of the comparator, U1, whose output triggers SCR1, which in turn activates power relay K1 and shuts down output power. The whole process takes about 25 ms in the worst case. SCR1, after being activated, remains on until the reset switch is pushed.

The test switch is used to

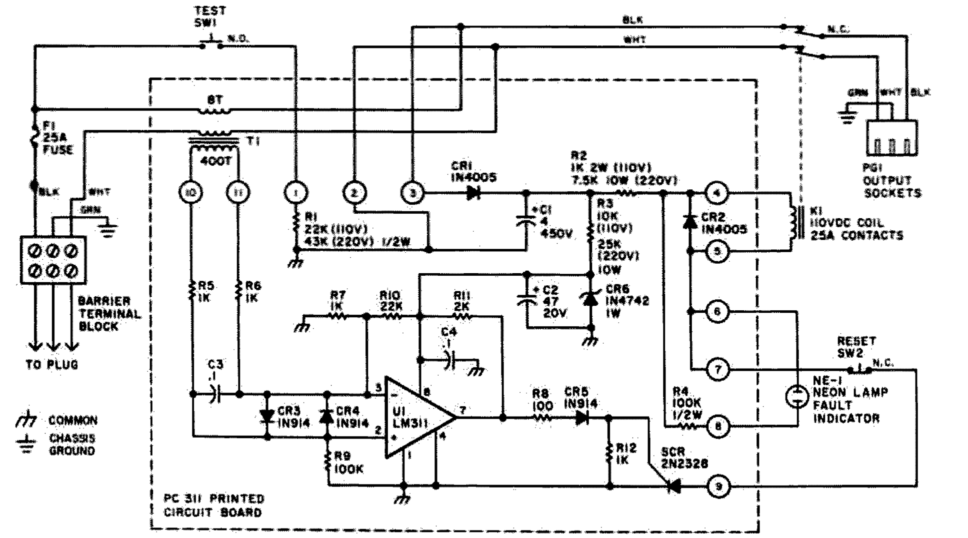

Fig. 1. Schematic diagram of portable ground fault interrupter—type 311.

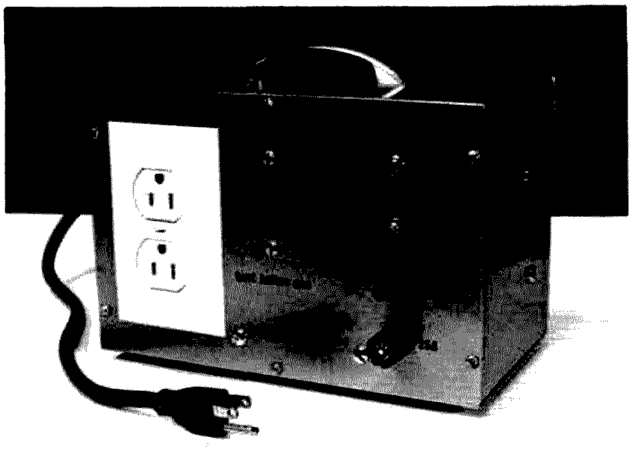

Photo A.

simulate a fault current of 5 mA for testing purpose. It is a good practice to test the system by the test switch prior to the use of the GFI. The neon light is used to indicate a fault and power-down condition.

For 220-V operation, a 220-V socket must be used for PG1; R1 must be changed from 22k to 43k; R2 must be changed from 1k (2 W) to 7.5 k (10 W), and R3 must be changed from 10k (10 W) to 25k (10 W). The GFI described was tested in close proximity to a high-power radio frequency transmitter and was found to be RFI-proof.

Construction

The complete system is housed in a 5″ × 6″ × 9″ steel box. Photo A shows the GFI and Photo B shows the component layout. A printed circuit board is used to contain all electronics components. The switches, relay, light, fuse, and socket are all mounted on the front panel, but a barrier terminal block is mounted on the inside of the side wall of the box for connection to the power line cord.

Operation Hints

If the GFI keeps shutting off with a certain load, it indicates that the load or the wiring to the load has a short which provides the fault (leakage) current to trip the GFI; such a fault must be sought out and corrected before the tool or the equipment is used. In some cases, even a very low current would do damage to certain persons; hence, by no means should a person subject himself or herself to any test shock. All common sense and carefulness must be exercised when electrical power is involved; the first mistake could also be the last. ■

Parts List

R1	22k (110 V), 43k (220 V), both ½ W
R2	1k (110 V) 2 W, 7.5k (220 V), 10 W
R3	10k (110 V), 25k (220 V), both 10 W
R4	100k ½ W
R5, 6, 7	1k ¼ W
R8	100 ¼ W
R9	100k ¼ W
R10	22k ¼ W
R11	2k ¼ W
R12	1k ¼ W
C1	4 uF 450 V electrolytic
C2	47 uF 20 V electrolytic
C3, 4	.1 uF 25 V disc
CR1, 2	1N4006
CR3, 4, 5	1N914
CR6	1N4742 12 V zener diode
SCR	2N2328
F1	Fuse holder and 25 Amp fuse
U1	LM 311 IC
SW1	SPST N.O.
SW2	SPST N.C.
NE1	Neon lamp and holder
K1	Relay 110 V coil, 25 Amp or 30 Amp contacts DPDT
T1	Differential transformer
PC311	Printed circuit board
Chassis box	5″ X 6″ X 9″steel box with handle

The following are available:

GFI kit	110 V	type 311-K	$55.95
	220 V	type 312-K	$65.95
Assembled GFI	110 V	type 311	$70.95
	220 V	type 312	$80.95

(all above plus $5.00 shipping and handling)

PC board	$10.00 ppd
Relay	$16.00 ppd
Transformer T1	$13.50 ppd

To order, send check or money order to: LOTRONICS, PO Box 975, El Cerrito CA 94530 (allow 3-4 weeks for delivery).

Poor Man's CW Memory

—works even with a straight key

Thanks, Elmer!

Eric Unruh WBØRYN
Rt. 2, Box 56A
Newton KS 67114

A dog may be a man's best friend, but for the CWer, a memory for his keyer has got to come in a close second. A memory makes everyday operating much easier and more enjoyable, and is almost indispensable during a contest. It's a worthwhile addition to any ham's station.

Why, then, do so few hams have them? "Well, my keyer is an oddball design; I don't have access to a free-running oscillator in order to synchronize it to the memory"; or, "I just use a straight key."

I had the same objections, but at the 1977 Field Day, a friend in my club, Elmer Watts KØHAO, told me that he had designed a memory that would work with any keyer—even a straight key! I was so delighted with my version of his design that I asked for permission to write it up. This is the result.

Most of the previous memories were designed to work with only one keyer or type of keyer, as the two had to be synchronized. That is, the oscillator on the keyer had to be exactly in step with the oscillator on the memory in order for a dot to be stored in one memory location and a dash in exactly three. One got perfectly-spaced CW out of such a memory, but it was tricky to build. What makes this memory unique is that you don't have to synchronize it with another oscillator.

The secret of this memory is in clocking it at a much higher rate than the keying speed. Dits are then stored in a number of memory locations, not just one, and dahs are stored in approximately three times as many locations as are the

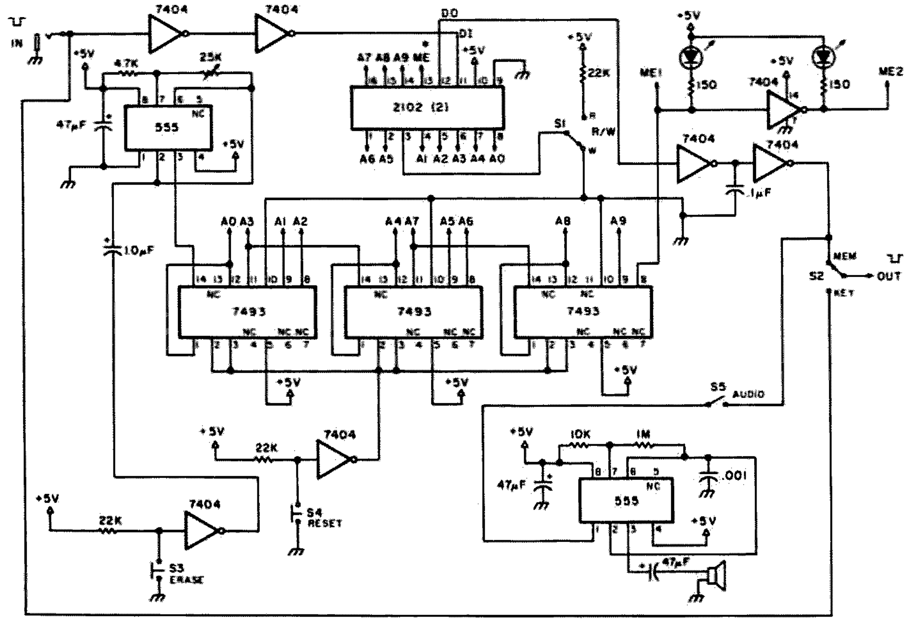

Fig. 1. The basic circuit.

dits. Running the memory in such a fashion destroys the perfect 1 to 3 ratio of a well-adjusted keyer, but the output of the memory is so close (1 to 2.9 or 3.1) that even the most critical ear can't tell the difference. The memory space certainly is not used in the most efficient way, but the advantage is that it can be used with nearly all keyers, bugs, straight keys, or sideswipers.

The basic circuit is shown in Fig. 1. It is straightforward and unbelievably simple. The heart of the circuit is two 2102 1K x 1 static RAM memory chips, for a total of 2K or 2048 bits of memory. They are wired up in parallel, pin for pin, except for pin 13, the memory-enable pin. More on this later.

A 555 timer is wired up in the astable multivibrator mode and clocks three 7493s, which are 4-bit binary counters. The speed of the clock can be varied by means of the 25k pot. The 7493s provide the ten address lines needed to address the 2102s (2^{10} = 1024 bits per chip). As we said before, the 2102s are in parallel except for the ME pins, because we want to enable only one chip at a time. (A logic 0 on the ME line enables the chip, while a logic 1 disables it.) This is accomplished by using an inverter section connected to pin 8 of the last 7493. In the starting position, where A_0 through A_9 = 0, ME1 will be low, ME2 will be high, and the first memory chip will be enabled. 1024 bits later, the first chip will have been addressed fully. Pin 8 on the 7493 will then switch high, ME1 and ME2 exchange logic levels, and the second memory chip will be enabled. In this way, both chips are used to their full capacity. The LEDs are there to give visual indication of when one memory has been cycled through and the other is starting.

Incoming data to the 2102s is fed through two inverters to pin 11 and can be keyed by any method in which key-down is represented by a logic 0. Although the two inverters look redundant, they are there for a reason. The DI pins tend to assume a low state if left floating. Since logic 0 = key-down in this circuit, this can't be tolerated; the two inverter sections are there to pull the DI pins high in the absence of an incoming signal.

Data-Out is available at pin 12. The two inverters and the capacitor following it are for shaping purposes. A switch, S2, is provided to allow the operator to choose between using the message stored in memory or using the key without going through the memory. Note, also, that the output drives a sidetone oscillator, another 555 in the astable mode. A switch, S5, is provided to shut off the audio tone when the memory is not in use. S4, the Reset switch, resets the memory to the starting point by bringing all the address lines to logic 0. S1, the Read/Write switch, controls whether or not data is written into the memory or is available at the output. The Erase switch brings one end of the 1.0-uF capacitor up from ground to a logic one when pushed, allowing the 555 clock to run at its top speed, around 200 kHz. The memory chips cycle through in just a fraction of a second, and if the Read/Write switch is in the Write position, it will clear the entire 2K of memory.

It should be noted that this diagram does not provide a way to key the transmitter, as different transmitters use different keying methods. Circuits for keying the two most popular types of transmitters (grid-block and cathode-keyed) are shown in Fig. 2.

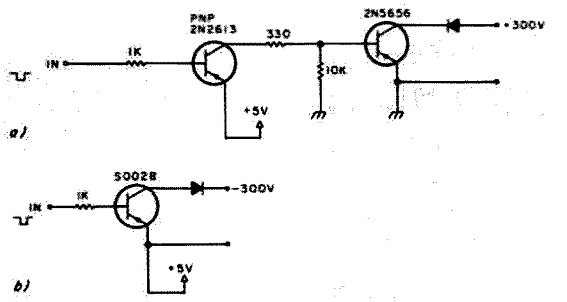

Fig. 2 (a) Cathode keying. (b) Grid block.

Construction can be as simple or as elegant as you desire. A well-regulated 5-volt supply should be used with adequate filtering. I have added 47-uF capacitors across the supply to the 555s; these should be placed as close to the 555s as is physically possible. 555s tend to generate a lot of garbage and glitches, and extra bypassing is needed to prevent these from being sent on down the line. Bypass capacitors on the order of .01 or so should be placed across the supply near all the rest of the chips, also; this is simply common sense when working with TTL and was not shown on the schematic.

As seven inverter sections are used, two 7404 chips are required. Any unused sections should have their inputs tied to ground.

The easiest way to parallel the two 2102s is simply to stack one on top of the other and solder the pins together. While it is surprising how much heat they can stand, don't overdo it; try to use a small soldering iron and solder quickly. Remember not to solder the ME pins together.

If one desires control over the pitch of the sidetone oscillator, the 1-megohm resistor on the 555 can be replaced with a trimmer pot.

Operation is simple. Turn the Memory/Key switch to the Memory position, turn the Read/Write switch to the Write position, turn the Audio switch on, reset the memories, and key in the message you want. When you're finished, switch the memory back to read and reset it. Your message should play back.

If the message is distorted, this means that the memory clock is not running high enough as compared with the keying rate. Either advance the clock rate or slow down your fist, and try again. Eventually, you will find a speed fast enough so that the message is recorded undistorted. The memory should be running as slow as possible, without distortion, in order to get a longer message into memory. Of course, once the message is in the memory, you can play it back at any speed you wish by simply varying the memory clock speed. Maybe this accounts for some of the 60 wpm plus signals we hear on the air!

Total cost for this memory is ridiculously low, with the most expensive components being the five switches. The 2102s are available nearly everywhere for under $2 each, 7493s under a buck apiece, 555s for 50 cents, and the 7404s for the whopping sum of a dime per chip. It really is a poor man's memory!

I hope you like the memory as much as I did. I'll be glad to answer any and all questions if you send me an SASE. ■

Power Up for Mobile Operation

—adding an auxiliary battery

Wiring a winner.

It certainly puts a damper on the pleasures of mobile operation if you have to worry that the next push of the mike button will drain the battery to the point where the car will not start. It kind of spoils the fun of having that new super linear that draws 100 Amps from the battery on transmit, doesn't it?

What is there to do about it? You could, of course, keep the engine running while you are operating, but that wastes gas if you are not in motion. A better solution is to connect your radio equipment to an auxiliary battery—a separate battery that is charged by the alternator when the engine is running, but is disconnected and isolated from the main or starting battery when the engine is stopped. That way, you can run the auxiliary battery down even to the point of total discharge, with the main battery remaining charged and ready to start the engine.

Furthermore, there is a wide variety of electrical appliances, ranging from refrigerators to bed warmers, that can enhance the comfort of living in a van or camper. Again, you can get the most out of these conveniences only if you don't have to worry about running down the starting battery. Large motor homes and other recreational vehicles are all equipped with auxiliary batteries. They are available as optional equipment in some makes of vans and in most makes of pickup trucks. One can be added, using aftermarket components, to any vehicle that has room for an extra battery.

As a point of reference for the following discussion, Fig. 1 shows a simplified view of the normal car or truck electrical system, specifically, the part devoted to charging the battery. You can see how the alternator provides power to the vehicle circuits and charges the battery through the ammeter. The alternator field is supplied by the regulator, which receives power through the ignition switch and senses the voltage that it receives.

To install an auxiliary battery, you must first find room for it. Some vans and most pickup trucks have room under the hood. For these, battery trays are commercially available for about $10. Some cars might also accommodate an extra battery under the hood.

If there is not room under the hood, you can install the battery in the trunk of a car or under a bed or within a cabinet in a van. The space occupied by the battery should be vented to the outside to prevent accumulation of the hydrogen gas given off by the battery when it is being charged. Plastic battery boxes are available at trailer supply stores. These are useful for protecting the battery and for keeping battery acid off other things.

You must, of course, have a battery. An ordinary car battery will do nicely and is commonly supplied when an auxiliary battery is ordered with a new vehicle. However, it is not optimal for this application. An ordinary car battery is designed for so-called "floating" service, where it is kept continually at or near full charge by the alternator and only dis-

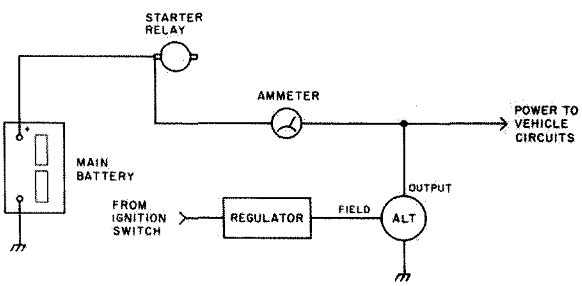

Fig. 1. Simplified circuit of automobile electrical system.

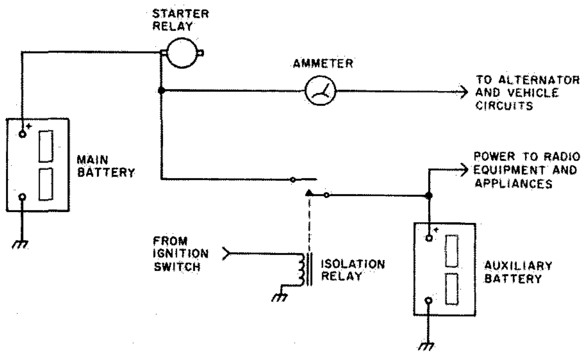

Fig. 2. Auxiliary battery with relay isolator.

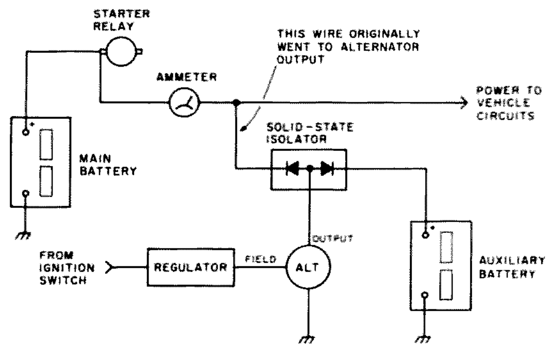

Fig. 3. Auxiliary battery with solid state isolator.

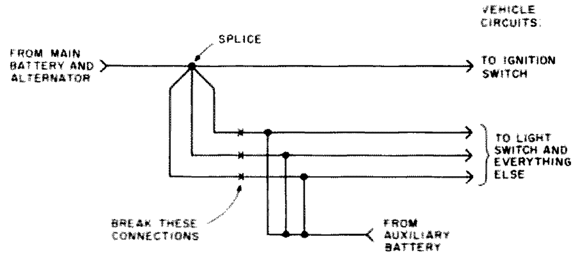

Fig. 4. Powering vehicle circuits from auxiliary battery.

charges a small fraction of its capacity by the normal engine start.

An auxiliary battery, in contrast, is subject to so-called "cycling" service, where it may discharge a large fraction (or all) of its capacity, if not completely, when electrical equipment is used with the vehicle and the engine off. (The discharge and subsequent recharge by the alternator constitute a "cycle" in battery parlance.) This sort of service is hard on a battery and hastens its deterioration by such occurrences as the shedding of active material from the plates. A battery that is designed for cycling—say, a marine battery such as the Sears Die-Hard Marine—will cost more than a car battery, but will last longer in this type of service.

The final item you will need is an isolator, whose function is to disconnect the auxiliary battery from the main battery when the engine is not running. This is available from recreational vehicle supply stores. Be sure to get an isolator with a current rating equal to or greater than the output rating of your alternator.

There are two types of isolator—relay and solid state. The relay isolator is the cheaper of the two, so (naturally) it is always used when the auxiliary battery is put on the vehicle at the factory. A diagram of the arrangement is shown in Fig. 2. It consists simply of a contactor relay (looking something like a starter relay) that connects the auxiliary battery in parallel with the main battery when the ignition is on. The auxiliary battery then receives a charge. When the ignition is off, the relay opens and the auxiliary battery is isolated.

This is a workable arrangement, but it has three disadvantages. First, if the load on the auxiliary battery while the engine is running exceeds the alternator capacity, current will be drawn from the main battery. Second, if the two batteries are at different states of charge, heavy currents will flow from the stronger one in to the weaker one when the ignition is turned on. Finally, the relay contacts are subject to deterioration.

The solid state isolator avoids these disadvantages. As purchased from a recreational vehicle supply store, it looks like a very mysterious box with cooling fins on the outside and the internal workings inaccessible. It costs about $25. However, as shown in Fig. 3, all there is to it is a pair of high-power diodes mounted on a heat sink. The anodes of the diodes are both connected to the output terminal of the alternator, while the cathodes are connected to the two batteries. Thus, current can flow from the alternator to both batteries, but not from one battery to the other. The regulator continues to sense the voltage of the main battery and thus compensates for the diode drop.

You can save a little money by making your own isolator. Simply procure two diodes with current ratings equal to or greater than your alternator output rating. The lowest voltage rating offered, commonly 50 volts, is adequate. Mount them on a heat sink (with adequate insulation of course) and hook them up.

To install the solid state isolator, find a place to mount it near the alternator. Remove the heavy wire from the alternator output terminal and connect it to one side terminal (i.e., one diode cathode) of the isolator. (This wire will carry charging current to the main battery.) Prepare a new heavy lead and connect it between the alternator output terminal and the center terminal of the isolator (i.e., the two diode anodes). Connect the remaining side terminal to the auxiliary battery.

Whenever you do any electrical installation work of this type, it should go without saying that you first disconnect the ground cables from both the main and auxiliary batteries. Otherwise, expensive fireworks will occur.

Use number 10 or heavier wire for the power connections between the alternator, isolator, and batteries. A kit of crimp-type terminals is extremely useful for this sort of job.

Once you have an auxiliary battery, you can get a lot more benefit from it by rewiring the vehicle electrical system so that the lights and other accessories are connected to the auxiliary battery, and only the items controlled by the ignition switch remain connected to the main battery. That way, you won't have to worry about running down the main battery if you leave the lights on, either inadvertently or for safety, or if you plug something into the cigar lighter socket on the dashboard.

Because of the wide variations in the details of car and truck electrical systems, I can present only general guidelines for making this change. See Fig. 4. Start by studying your vehicle's wiring diagram. Look for a splice where the main power wire from the battery, ammeter, and alternator branches out to the ignition switch, light switch, and other accessories such as the cigar lighter (possibly passing through the fuse box on the way). Cut all wires away from this splice except the ignition switch wire and the feed wire from the battery. Connect the wires you have cut loose to the auxiliary battery.

Normally, vehicles with auxiliary batteries have not been wired in this way. (My van is probably the only one until this article appears.) Making the change will, in all likelihood, involve you in working with the tangle of wires under the dashboard, but the results are well worth it.■

Project Update

—doubled capacity for K2OAW's repeater IDer

Just add three ICs.

Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

Quite a few repeaters around the country are using the K2OAW repeater control and CW identifier published in *73 Magazine*, February and March, 1973.

The identifier used a simple diode matrix for memorizing a call consisting of up to 32 dits, dahs, and spaces. That was sufficient even for long repeater calls such as WR2XXX. But the FCC

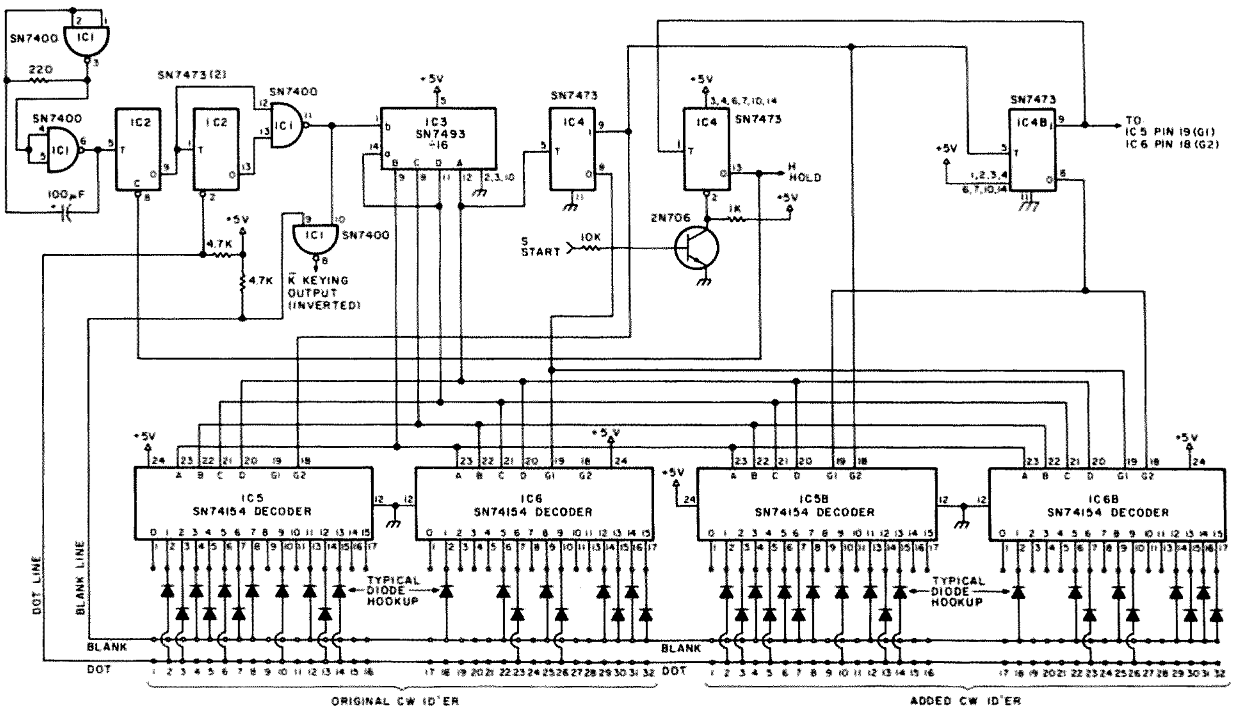

Fig. 1. CW identifier as modified for 64 diode positions.

recently changed the rules—no new WR calls will be issued and individual calls followed by /RPT are to be used. Now, even a simple call such as K2EEE/RPT is too long to fit into the 32-bit limitation.

Snort of designing a completely new identifier, the easiest solution for repeaters which must change to the new call system is to simply add three new TTL integrated circuits as shown in Fig. 1.

The three new ICs are IC4B, IC5B, and IC6B. IC5B and IC6B are connected exactly the same as IC5 and IC6 on the original board and extend the diode matrix to 64 bits. Diode matrix wiring is exactly the same as before, with diodes scanned from left to right.

IC4B is a new flip-flop which is connected between the two halves of the old IC4 to extend the counter from 5 bits (which would access 32 diodes) to 6 bits (to access 64 diodes). The wiring to the G1 (pin 19) and G2 (pin 18) inputs to all four 74154 decoders is now different.

The new ICs and diodes can be installed on a perforated board which connects to the original printed circuit board with 11 wires, counting +5-volt power and ground. I also have several of the original identifier boards, which I will be happy to sell ($7 each) to anyone who would like to mount the new board piggyback above the old one.

So, if you have to change your repeater's call, go ahead and make this modification. It's a lot easier to modify the present identifier than to start all over. ■

Microcomputer Interfacing

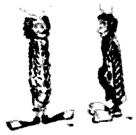
from page 14

programs back into memory. In any case, when errors are found, you will probably want to reedit and reassemble the software to produce a complete, error-free, documented listing.

Since most programs will contain errors, it may be a good idea to have the debug program as a permanent part of your computer. The storage of a debug-type program in read-only memory (ROM or PROM) is wise since "runaway" programs being tested might alter the debug software, causing you to have to load it again. There are many debug or *monitor* programs available, with Intel Corporation's Insite software library listing at least four. The editor/assembler programs may also be resident in PROM, and the low cost of both read/write memory and PROM chips suggests that many users will keep standard system programs such as editors, assemblers, and debug resident in their systems. The alternative is a paper tape, cassette, or disk-based software package which must be read into memory before each use.

There are also cross-assemblers which will generate an assembled program, but for some other computer. For example, a PDP-11 might be able to cross-assemble 8080 microcomputer programs. Cross-assemblers can be powerful programs, since some incorporate simulation programs to test the program, too.

The program we use for testing programs is DBUG written by Dr. Chris Titus,* and the assembler output shown in our program examples is that produced by the Tychon Editor/Assembler (TEA). Both are resident in our 8080 system on PROM chips.



*"DBUG, An 8080 Interpretive Debugger," Titus, C.A., E & L Instruments, Inc., Derby CT 06418, 1977.

Contests

from page 18

band at the same time.

EXCHANGE:

OM stations send RS(T) plus 2 digits denoting the operator's age; YL stations send RS(T) plus 00.

SCORING:

For non-Asian stations: Score 1 point per Asian QSO; multiplier is the number of different Asian prefixes worked on each band according to WPX rules. Asian stations score 1 point per non-Asian QSO; multiplier is the number of different countries in the world worked on each band according to the DXCC countries list.

Note: JD1 stations on Ogasawara (Bonin and Volcano) Islands belong to Asia. JD1 stations on Minamitori Shima (Marcus) Island belong to Oceania. Contacts among Asian stations and among non-Asian stations will not count for QSO points or multipliers. Contacts with KA stations are not eligible! They are considered not amateur, but military!

ENTRIES AND AWARDS:

Please use official contest log and summary sheets or other similar forms. Please keep all times in GMT and fill up the blanks of "multiplier" by the countries or prefixes only the first time on each band. A number of awards will be issued depending on the number of entries from each country in each class. Disqualification may result for violation of the contest rules, false statement in the report, or taking points for duplicate contacts on the same band in excess of 2% by the total. The log and summary sheet must arrive together at JARL, PO Box 377, Tokyo Central, Japan, on or before the following dates: phone—September 30th; CW—November 30th. You may have contest results by enclosing one IRC and SAE with your log.

WEST VIRGINIA QSO PARTY
Starts: 2300 June 16
Ends: 2300 June 17

All amateur radio operators are invited to participate in this year's party sponsored by the West Virginia State Amateur Radio Council. The same station may be worked on different bands for additional points. Only one contact with each station per band may be counted for scoring. West Virginia stations may work each other.

EXCHANGE:

QSO number, RS(T), and WVA county or state/country.

SCORING:

Out-of-state stations multiply the number of eligible QSOs with WVA stations by the number of different WVA counties worked. This total is then multiplied by the power multiplier indicated below. WVA stations multiply the number of eligible QSOs by the sum of the different WVA counties, states, and countries worked. This total is then multiplied by the power multiplier: dc input of 200 Watts or less, multiply by 1.5; dc input of 201 Watts to legal limit, multiply by 1.0.

ENTRIES & AWARDS:

To be eligible for an award, a station may have only one unassisted operator and logs must contain a minimum of 50 valid contacts (20 for Novices). Logs must be received no later than July 15th and logs will not be returned. Logs must indicate the date, time, QSO number, callsign, their QSO number, signal report, and county/state/country or station worked, mode, and band. Awards will be issued as follows: highest-scoring WVA resident, 1st runner-up WVA resident, 2nd runner-up WVA resident, highest-scoring Novice WVA resident, highest-scoring station from each state, highest-scoring station from each country, and highest-scoring Novice from each state. Decision of the Contest Committee of the WVA State ARC will be final. Logs should be sent to: West Virginia QSO Party, PO Box 36, Seneca Rocks WV 26884. Suggested operating frequencies are 35 kHz inside each CW band and 10 kHz inside the general portion of each phone band.

7-LAND QSO PARTY
Starts: 1200 GMT June 30
Ends: 2400 GMT July 1

This is the second annual QSO Party sponsored by the NAS Whidbey Island ARC. The 7-land area includes the 8 US call district states, the VE7 call area of Canada, and the KL7 area of Alaska.

Operating time is limited to 30 of the 36 contest hours. The same station may be worked on each band, and contacts between 7-land stations are permitted for multiplier and QSO credit.

EXCHANGE:

All stations: RS(T)/contact no. /state, province, or country. 7-land stations include county.

SCORING:

One point per QSO for 7-land stations. Five points for each 7-land contact for all other stations.

Multiplier: 7-land—one multiplier for each of the 50 US states and 13 Canadian provinces on each band. All others—one for each state or province worked in the 7-land area, maximum 13 on each band.

Power Multiplier: 5 Watts or less—x5.00; 5 to 100 Watts input—x2; 100 to 299 Watts input—x1.5; 300 to 499 Watts input—x1.25; over 500 Watts input—x1.

Final score is QSO point total x sum of band multipliers x power multiplier.

AWARDS:

Certificate to each top-scoring single op in each state, province, and DX country.

Certificate to each top-scoring multi-op, single transmitter in each W/VE call district.

There will be no multi-multi category.

All stations operating outside the call district indicated by their call must sign portable.

LOGS:

Logs must show band, mode, date and time in GMT, station worked, exchange sent and received, points.

Use a separate sheet for each band and include a dupe sheet if your entry includes over 100 contacts.

Make your own log and dupe sheets. However, a summary sheet can be obtained from WB7NVM if an SASE accompanies the request.

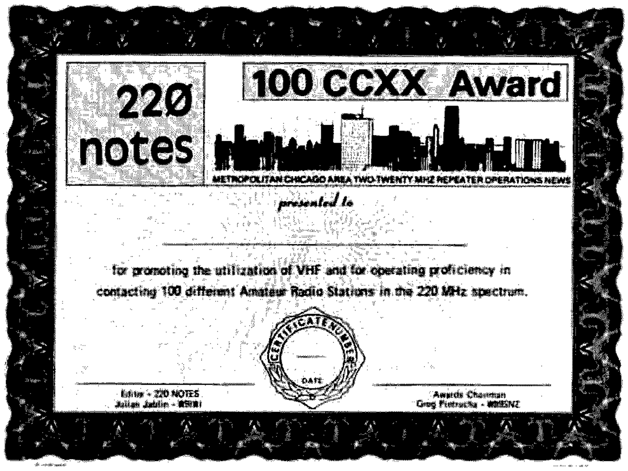
Include an SASE with the entry. Mailing deadline is August 1, 1979. Mail entries to: NAS Whidbey Island ARC, c/o Lloyd Vancil, 3541 Appian Way, Oak Harbor WA 98277.

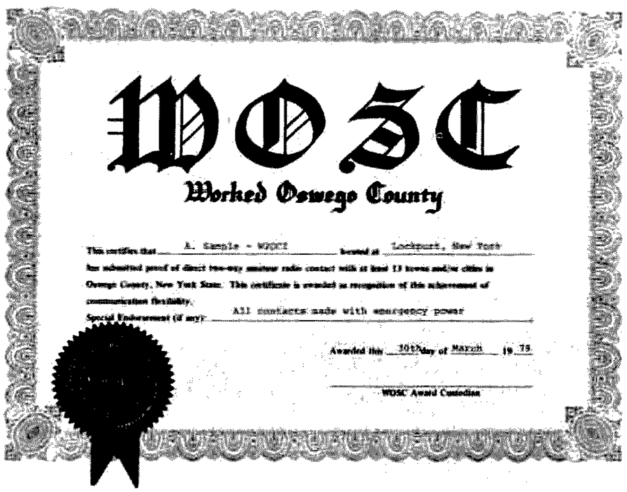
220 NOTES—100 CCXX AWARD

An attractive certificate is awarded to amateur radio operators who contact 100 separate stations anywhere in the 220-MHz band *after* receipt of the official logsheets. Contacts may be made through any repeater or via simplex. Please keep a dupe sheet to avoid disqualification caused by duplicate entries. Logs may be obtained from WB9SNZ; include an SASE. Completed logs should be mailed with $1.00 to *220 Notes*, to: Greg Pietrucha WB9SNZ, 2216 N. Kildare Avenue, Chicago IL 60639.

THE WORKED OSWEGO COUNTY AWARD

The Worked Oswego County Award (WOSC) is available to any amateur radio operator who works amateur radio stations in at least 13 of Oswego County's 24 towns and cities. A gold-seal endorsement is available to those who work all 24 cities and towns.





All direct two-way contacts (made without the aid of a repeater) made after January 1, 1978, count toward the award. All contacts must be made from the same station at the same fixed location, or, if mobile, from within five miles from the licensed location. Contacts with all fixed or mobile stations count on any amateur band. Multiple contacts with the same station portable or mobile in a number of town or city locations is permitted for the purpose of making additional town or city contacts.

A special endorsement is available if contacts with all cities or towns are made using emergency or battery power.

Applicants should list the time, date, frequency, mode, and power used, along with station contacted and location (town name or city). This is the usual information that would be filled in on the standard ARRL log. The list of 13 or 24 contacts should be mailed to the Award Custodian along with a self-addressed, stamped return envelope. QSL cards are not required, but the spot log check requests to the stations listed may be made by the Award Custodian.

There is no charge for this award. The award is sponsored by radio station WOSC to encourage contact with all areas of Oswego County and test station capabilities. The rules and qualification specifications may be changed from time to time by the Award Custodian. In the case of questions and disputes, the decision of the WOSC Award Custodian is final. The Fulton Amateur Radio Club will act as custodian for the award. Its mailing address is: PO Box 246, Fulton NY 13069.

Official WOSC List of Oswego County Towns and Cities

Oswego Town	Richland
Hannibal	Sandy Creek
Granby	Boylston
Minetto	Orwell
Scriba	Albion

Looking West

from page 6

operator assigned the callsign indicated hereunder. I actively operate in the presently-allocated 220-MHz amateur band, using my own equipment and through repeaters representing substantial investments of cash and technological effort.

In a portion of Docket 20271 (Par. 103 and 124) concerning its position to WARC on frequency allocations, the Commission proposed that the present 220-225-MHz amateur radio frequencies be allocated primarily to a new use by the maritime radiotelephone service.

I am not aware of any Notice previously issued regarding this proposed allocation. This portion of the Report and Order clearly affects my rights and the rights of other licensed amateur radio operators to the 220-MHz band. A formal opportunity for amateur radio response would demonstrate that the 220-MHz band is in active use throughout the United States, presenting an attractive alternative to the crowded 2-meter band.

Growth of "220" had previously been restricted by the threatened allocation of the frequencies to Citizens Band use. However, since the Commission denied that proposal, amateur use of the band has flourished.

I join with the 220-MHz Spectrum Management Association of Southern California in its petition to withdraw the affected parts of Docket 20271, and to set that matter for comments and hearings in an appropriate framework as required by law.

Respectfully submitted,

/s/

Date:
Name/Call:
Address:
City/State:

Thanks to *220 Notes*, here is an easy way for you to join in the fight to save 220. Lee Knirko W9MOL and Julian Jablin W9IWI, who prepared the special "Action" bulletin, suggest that you do one of the following with the letter:

1) Make one copy and 14 photocopies, and send all 15 to the Secretary of the FCC in Washington; or

2) Send just one copy to the FCC (which will at least put you on record as opposing the US 220 WARC proposal, although it will not be considered an official reply by the Commission); or

3) Look over the points made and draft a letter in your own words to the same effect. This is the best method, although it takes the most time. Then go out and again make 14 photocopies and send all 15 to the Commission as your official reply; or

4) If you do draft your own letter but do not have the time to copy it, at least send it to the FCC as fast as possible.

The idea here is for the amateur community to show its support for the one lone Petition for Reconsideration on this matter which was filed on time. Without such support, the 220-SMA has little chance of accomplishing much. With your support, the FCC will be forced to take notice.

Lee and Julian also suggest that you send copies to your senators and representatives, as well as to Dave Sumner at ARRL HQ. I might also suggest that copies be sent to the 220-SMA of Southern California, to the Westlink Amateur Radio News Service, and to myself.

THE CB BANDITS DEPARTMENT

Abuses of CB operation were given a good look on the morning of April 5th on the National Broadcasting Company's "Today" program. In a segment entitled "CB Bandits," produced at NBC's Burbank facilities by Scott Goldstein, NBC correspondent Jack Perkins explained to the public the myriad of problems now prevalent on the 11-meter Citizens Band by visually documenting many of the more common abuses in the CB service.

Shown were such regulatory violations as the use of excessive power, DXing, and even the playing of music on 11 meters. In the case of the latter, a female CB operator in the midwest was shown running an on-the-air CB music program from taped cartridges through her CB set and linear amplifier. Other scenes depicted how "CB bandits" who run excessive power make life miserable for both the legal CB operator (who wishes to use 11 meters for its intended purpose) and his neighbors, in the form of excessive TVI and BCI. The FCC was given its say on this problem through Los Angeles Engineer-in-Charge Larry Guy, who stated that such operations were indeed illegal and noted that if all CB operators obeyed the regula-

tions, there would be no need for amplifiers and the like. The report showed the FCC's enforcement operation here in southern California, but explained that although the FCC attempted to keep control over CB, it was hampered in this due to a lack of staff. It gave a figure of 400 FCC employees nationwide who were trying to police more than 15 million CB operators.

Perhaps the most vivid portion of this 5-minute, 30-second segment was mini-cam coverage of a business in Costa Mesa, California, known as Pacific Coast Communications, which the report alleges to be a supplier of illegal power amplifiers and similar equipment. To radio amateurs, this particular piece has important significance in that it visually gives credence to what many amateurs have said for a long time—that the FCC's linear amplifier ban on such devices operating in the spectrum from 24 through 36 MHz is nothing but a bureaucratic farce which punishes the law-abiding amateur for the sins of another radio service. The ban has accomplished only one thing: It has created a rather healthy black market for such equipment. I suspect that operations such as PCC are more the rule than the exception. Maybe the contents of the "Today" report will get through to the Commissioners the fact that their "easy way out" was not the right road to follow after all. The inability of the FCC to cope with the CB problem won't be easily forgotten.

Whether they realize it or not, the "Today" program producers have performed a service for amateur radio. They did not lump amateur and CB operations together (as is often done by the broadcast media), and they graphically pointed out the real world of CB and the problems it faces today. Moreover, they may have given amateurs the kind of ammunition needed to shoot down the unconstitutional, unwarranted, and illegal ban on 10-meter amplifiers.

COMMENTARY

The NBC report neglected to mention one important item—that the problems depicted were big-city ones not often found in the outlying areas. Los Angeles CB operation is a mess. It's virtually impossible to hold a QSO of any consequence because of the many CB bandits like those depicted on "Today." This holds true for most cities of any size. However, once you get away from the big cities, things are quite different; the CB bandit is definitely a minority figure in such locations.

One other point missed by the NBC presentation was the difference between AM and SSB operation. Only unstructured AM was shown, which in big-city CB is a no-man's-land. Not mentioned were some of the structured and voluntarily-policed SSB operations. However, it is hard to really criticize this report on either of these points, since the obvious aim was to enlighten the public about the current problems of 11-meter CB. Considering the constraints imposed by the exact timing that TV broadcasting requires, I must say that NBC has done a rather outstanding job.

* * *

In a late-breaking development, the FCC acted the week of April 1st to deny the 220-SMA Petition for Reconsideration of Docket 20271. The FCC based its denial of this and eight similar petitions on the grounds that over four years had been spent on the preparation of the WARC proposal and that, during that time, all interested parties had been given ample time to comment. However, it must be noted that during this four-year period, not once was there a mention of reallocating 216 through 225 MHz to the maritime service and, therefore, there was no way in which concerned amateurs could comment on the matter. Many 220-MHz amateurs feel that both the maritime service and the FCC have directly violated the federal government's Administrative Procedures Act and stand ready to take whatever legal action is necessary to prevent the implementation of the WARC proposal.

RTTY Loop

from page 20

tions with special data, these characters can be used as software switches to accomplish special functions. The special codes detailed above, for example, translate to:

$00—The null is stored for control codes which have no function in Baudot, e.g., $01, $02, $1F, but not those with a function, as the BELL ($07).

$FF—A DEL is stored for certain "special" printable characters not found on the Baudot keyboard.

$FE—Stored at the first location of the table, $FE will be sent as LTRS when a NULL is input from the keyboard.

After the table value is retrieved, it is tested for $FF, and, if present, a branch to SPLCHR is executed. This routine handles those printable characters, like *, %, and @, that are not represented in Baudot. Another test for $00 directs a branch back to the input if present. Thus, control codes do not even start the outputting routine.

If there is no "special case," then the Baudot output sequence is initiated. The MSB of the data retrieved from the table encodes LETTERS or FIGURES case. The routine diagrammed in Fig. 3 shows how the shift is read, compared with the current case, stored, and changed if necessary. It should be noted that SPACE, CARRIAGE RETURN, and LINE FEED are all sent as lowercase (LTRS) characters. Thus, downshift when spacing or when sending a new line is ensured.

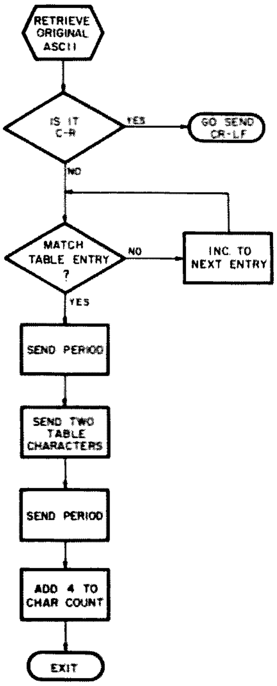

Fig. 5. SPLCHR routine.

Having established the shift, the actual character is output, using the routine shown in Fig. 4. This routine loads the carry bit with the five remaining data bits in the accumulator, keeping track of the bit number with a counter. If the carry bit is a "1", a MARK is sent; a "0" sends a SPACE. START (22 ms SPACE) and STOP (31 ms MARK) bits are also appended, thus creating true TTY format.

Should you have encountered one of those "special" characters we mentioned above, a branch to SPLCHR would have brought you to a routine diagrammed in Fig. 5. Here, the original ASCII character input is retrieved from the table pointer where it was stored. If it is a carriage return, a branch to a routine called CRLFOT will send the string CR-CR-LF-LTRS-LTRS, a "standard" way of initiating a new line in Baudot, and echo a CR-LF on the terminal. Otherwise, a period (.) followed by two letters and another period fill in for the missing character. Fig. 6 shows the codes used for the ASCII characters encoded.

The flowcharts shown this month comprise an overview of a practical means of Baudot transmission with a computer.

ASCII	Symbol	Baudot
$23	#	.NR.
$25	%	.PC.
$2A	*	.AS.
$2B	+	.PL.
$3C	<	.LT.
$3D	=	.EQ.
$3E	>	.GT.
$40	@	.AT.
$5B	[	.((.
$5C	\	.BS.
$5D	]	.)).
$5E	↑	.UP.
$5F	—	.UL.

Fig. 6. SPLCHR conversions.

Next month, I will go into a program to implement this scheme on an SWTPC 6800 computer. Input shall be through the control interface. An MP-S ACIA-type input is preferred, although the MP-C PIA-type board will suffice. Output shall be through one bit of a PIA board (MP-L) on port #7.

Regards this month to Melvon G. Hart W0RV in St. Louis MO. Melvon is using Teletype™ gear now, but we hope with the program now developing, and others, he will soon be able to get that SWTPC system on RTTY! He also lets us know that an active two meter RTTY net is on in St. Louis, on 146.70 MHz, AFSK. Thanks for the info, Mel.

Ham Help

I have a niece in Corpus Christi TX who is interested in becoming a ham. She is 8 years old but sharper than I in some ways. Is there a group in Corpus Christi who could help out with this project? Thanks.

Port Saint Joe FL 32456

OSCAR Orbits

Courtesy of AMSAT

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

OSCAR 8 Orbital Information

Orbit	Date (June)	Time (GMT)	Longitude of Eq. Crossing °W

Corrections

This is to express thanks to all CW music fans for corrections and suggestions for improvements for the keyboard described in the February issue of *73* ("This Station Plays Beautiful CW").

A note from KA1ADF (Speedy) arrived one day before I received my copy of *73* and pointed out: (1) The 10k resistors of Fig. 1 are not shorted out as the print indicates; (2) The callout for Fig. 2 should show 4071 for U7; and (3) U10 is a 4049. WA0KZL points out that the diodes are 1N4148, not as indicated in the callout for Fig. 1. Actually, about any diode will work. Even the cheap 1N4001 will do fine. Along with thanks to Tex goes my apology to Susan Philbrick of the *73* staff. She questioned this and I gave her a wrong answer.

W1ZB reports that he has built 20 keyboards over the years and is now going back to the diode matrix after trying many other methods. His next keyboard will use CW music logic but will replace the 40105 FIFO with the Fairchild 3341 to give a 64-letter buffer. For those who want a larger buffer, this is a good way to go.

DA1WD wants a memory for canned messages. An RCA CPD1823SD RAM interfaced between the 40105 FIFOs and the shift register ought to work. I have not made one like this, but it looks good on paper and will give 128 letters. If 256 letters are desired, a pair of CD1822SDs would do the job.

WB5RVH is on the air with an all-plastic case, using a converted UNIVAC surplus terminal and a rechargeable nicad power pack. He reports RFI problems when using the charger plugged into the ac supply. No problem without the charger. Suggest adding 0.01 uF bypass capacitors on all in/out lines. Electrolytics do a good job of filtering but are poor for rf bypass.

The worst problem of all is availability of the 40105 FIFO. This chip is made by RCA and Motorola and is available from the big houses such as Cramer, Hamilton, and Semiconductor Specialists. Unfortunately, all of these distributors have a hard-nosed $25 minimum order policy. On top of that, they often do not stock all other required chips. I was about to believe that it would be necessary to go to Japan for service when I decided to check the *73* advertisers—see Daytapro on page 183 of the February issue. Send Neil K9WRL an SASE for a quote on a chip package. He promises he will supply the 40105. By the way, if your hobby time is hard to come by, use the top line of chips. Specify RCA buffered "B" line, or equal. A typical number is CD 4071BE. After you have one keyboard working, you can test "bargain" chips easily.

Several others have written for diagrams on keying circuits and sidetone oscillators. Sorry, but I did not make drawings. I just hooked up the components per typical sketches, such as shown by VE3CW4 on page 107 in the February issue.

As hams notify me that they are on the air, I will send them a "CW Music" number. Who is going to be #3? Let's hear more CW music. Even if you don't care for a keyboard, good code makes operation a pleasure and can be sent by all methods of keying.

We would like to point out that one of our articles ("Universal Alarm Circuit," March, 1979) is very similar to one which appeared in the December 11, 1975, issue of *Electronics* ("Multiplexed detectors isolate water leaks"). F. E. Hinkle, Jr. K5PA (Austin TX) holds US patent number 4,090,193 on this device.

Managing Editor

Ham Help

I need a schematic diagram for an Electronic Counters, Inc. (ECI), Pulse Generator, Model 5101. If someone has a copy to share, I will pay for reproduction and mailing. Thank you.

Russell Steele
838 Gayle Street
Papillion NE 68046

I need a manual for a Conar Model 80 solid-state television kit. I also need any kind of information on a 1928 Model 3 Eveready ac receiver and a possible matching transmitter. Any help with these items will be deeply appreciated. Thanks.

Peter H. Oesterle VE3HOH/W3
RD #1
Orwigsburg PA 17961

I am attempting to make a list of optometrists who are amateur radio operators. Presently, I know of about 15, and I am sure there are more out there. Perhaps an informal net could be started. All QSLs will be appreciated. Thank you.

Dr. Thomas W. Byers WB9YTG

River Forest IL 60305

I would appreciate any information on a 4-inch Western Electric 0-1-0 milliammeter. It has 6 terminals on the back, labeled AC1, AC2, DC +, DC −, DC ±, and R.

LETTERS

from page 13

several additional pieces of gear to the station. Not only are the products at the top of the line in features, design, and reliability, but also I have called them on two occasions for advice in application of some of the equipment and have universally been treated respectfully and promptly. On each occasion, I was referred to the amateur radio department and have found the information readily available, helpfully given and interpreted, and additional recommendations made.

The attitude and cooperation are truly exemplary. The speed and completeness of the service department is outstanding, and the basic design and presentation of the products are unbelievable. I would not hesitate to recommend this company and their personnel to anyone wishing a complete package of up-to-date equipment backed by all the technical and service expertise that could ever be needed, and all presented in a speedy, courteous, and comprehensive way.

Portsmouth VA

TURKEYS

Never in my wildest dreams would I have ever thought I'd be subscribing to *73 Magazine*. Until now, I have considered it just a cut above *Popular Electronics* as far as contents. Things like how to build a moisture detector or fuse testing made simple simply did not appeal.

Your February issue, however, has caused me to rethink my position. The article on the 8080 control system makes me feel that you may be getting around to some serious amateur projects. I did read the article, "The 2 Meter ECM Caper," and I am appalled at the fact that you could publish something tantamount to sanctioning the jamming of another amateur station. Granted, the amateur in question may have used improper or illegal methods to obtain a license, but at that time, he was still a licensed amateur.

I realize that you have to sell magazines in order to provide livings for you and your staff, but I personally feel that articles providing the "turkeys" with new ideas are not in the best interest of anyone associated with amateur radio. Lord knows, we have enough problems without causing new ones.

Van Nuys CA

DX

from page 22

OK3TAB/D2A is in Angola and will be there for one year. He has a beam up and is a very good operator in handling the pileups. QSL to OK3ALE.

The Northern California DX Foundation shipped a new linear amplifier to Easter Island to help boost the signal of Father Dave CE0AE. You should be hearing the results by now.

Beginning in July, EL stations in Liberia will be signing 5L for the remainder of the year.

KH3AA is a civilian on Johnston Island and is available for skeds. Write to John at Box 69, APO San Francisco 96305.

In case you have been looking for San Marino, there are eight licensed true-blue stations. These are M1B, M1BS, M1C, M1D, M1H, M1I, M1Y, and M1W. Good luck.

Liechtenstein and San Marino are often believed to be the smallest sovereign states in the world, but a mansion on the Via Condotti in Rome is probably the smallest of them all. This is the independent territory of the Sovereign Military Order of Malta. It represents an order founded during the Crusades and the order held the island of Rhodes for over 200 years. The order still issues its own passports and maintains its own diplomatic corps.

For some reason, the ARRL has refused to recognize the Sovereign Military Order of Malta as a separate country, but remember, it took the League 30 years to admit that there were two Germanys.

Here is the entire group that hoped to put VU4ARC on from the Laccadives last March. The DXpedition was well planned down to the last detail, even including medical personnel among the group, but was halted at the last minute due to tight security surrounding a visit to the Laccadives by the Prime Minister.

A new amateur in the American Embassy in Bangui has reportedly been issued the call TL8JAM. At this writing, he had no gear on hand but was awaiting shipment of some from the States. You should be hearing him anytime now.

Brother Ed HV3SJ has been sent to Colombia, thereby shutting down any regular activity from the Vatican.

QSLing for rare DX stations can sometimes be a bigger chore than ever imagined. Over 3,000 QSLs from 4U1UN went out to deserving DXers during February alone. W2MZV is now handling 4U1UN QSLs, so you can QSL direct to Herman if you desire. If you haven't snagged this one yet, look for them from Wednesdays 1900Z to 0100Z Thursdays in the 21355 kHz and 14240 kHz areas, plus or minus.

Pradhan A51PN reports that he is now handling his own QSLing. Look for him on 14005 kHz between 1200Z and 1230Z and on 14225 kHz between 1230Z and 1300Z. QSL turnaround is generally four to six weeks. Pradhan's activity has increased noticeably since the Southeastern DX Club shipped him an outboard vfo.

W1GNC reports sending back all the W0DX/Desecheo QSL requests because he never received any logs. This should not cause any problems since KP4AM/D is the only one being accepted for DXCC credit.

A station has been showing on twenty meters signing 3X1IX and saying to QSL to Box 477 there in Conakry. Some have wondered if this might be Slim. Back in 1963 there was a station signing 7X1IX, also saying to QSL to Box 477 in Conakry and also giving his name as Vlad. This station was legitimate and was operated by OK3UI, so there appears a very good possibility that 3X1IX is for real.

The Arabic Net meets each Saturday at 1900Z on 14250 kHz. Stations checking into this net include A7, A9, ST2, ST0, YK, YI, JY, and SU among others. If you need any of these for a new one, it might pay to take a listen.

LX1AG has been showing regularly twice a week on 14240 kHz at 2330Z. He says he plans to follow this pattern for some time and hopes to give a new country contact and QSL to everyone needing LX.

The ARRL has withdrawn all Sable Island credit for the operation last fall of VE1MTA, saying the station was not authorized.

K8NW wants us to let everyone know that he is not, repeat not, QSL manager for VR0M and should not be sent any more cards.

Due to a recent callsign shuffle, stations on Crete can be identified by their new SV9 prefix.

There has been a chain letter going around aimed at amateurs. All you have to do to claim untold riches, claims the letter, is mail one dollar to the proper address, then prepare twenty copies of the letter inserting your name in the proper spot, and mail them out to twenty ham friends. This chain letter is illegal because it asks for money. I wonder how it would work if, instead of money, the letter asked for blank DX QSL cards. Just think, you send one QSL to the name at the bottom of the list and a few weeks later you receive 8,000 DX QSLs ready for you to fill in your callsign. Instant Honor Roll. Actually, that kind of thing has been going on in CB circles for years.

DJ9ZB has out the latest edition of his up-to-the-minute QSL

Manager's Directory. This 6" x 8" softcover book runs to about 80 pages and is available direct from DJ9ZB for $5.00.

WB9OQU takes a list for those needing 4S7EA each Wednesday evening about 2310Z. 4S7EA shows up at 2330Z and usually stays around for about an hour. QSL to WB9OQU.

Herb Schoenbohm KV4FZ/NØVA has not backed off on his attempt to have Water Island declared a separate DXCC country. He prepared eight pages of strong support and fired it off to the DXCC desk there in Newington. Water Island remains a live issue with Herb.

FR7BP has requested that no IRCs, stamps, or dollars be sent for return postage since his mail is usually opened before he receives it and such items removed. Just send your card and he will reply via the bureau. It is usually best not to develop a habit of putting call letters on the outside of envelopes destined for overseas addresses. In some areas, this just brings unwanted attention.

D4CBS reports that plans for any S9 operation have been shelved for the immediate future. Angelo says that the possibility still exists but that the probability is just about zero.

Speaking of D4CBS, he is one of the first, along with AA6AA and W1NG, to reach the first plateau of 100 zones in the chase to earn 5BWAZ award #1.

A new DX club is being formed in the Baton Rouge, Louisiana, area. Drop a note to Jack Whitaker, 2327 Daggett Avenue, for more details.

That recent K1CO/PJ7 operation ran up 14,074 contacts in scoring some 12.3 million points. Not satisfied, they will add three more operators and try again in the CQ WW contest this fall. This will be a multi-multi operation from PJ7 and a multi-single operation from FS7. QSL K1CO/PJ7 to K3RLY.

OE6EEG along with DJ9ZB, F6BDS, and J28AZ are planning a possible upcoming effort from the Red Sea area including Abu Ail. They are exploring the possibilities of several areas and you should be hearing more on this soon.

North and South Yemen, 4W and 7O, long-time enemies, have decided it might be best for all concerned if they combined the two countries under one government. This would, of course, mean the deletion from the DXCC list of 4W and 7O and the addition of the emerging single nation. Being the opportunists they are, several DXers are already planning for the great event.

EP2LI reports that his next duty station will be in Qatar, A7, and that he plans to make every effort to reduce this one's standing on the needed lists. Mike had to abandon everything in Iran including rig, household goods, clothing, and the family bus. QSL to WA4PYF, who also has logs for A7XAH.

The Swiss Amateur Radio Magazine, *Old Man*, reported that HB9APN is at the Swiss Embassy in Peking and has been on SSB on 21155 kHz signing HB9APN/BY.

There is a feeling, going into WARC 79, by the FCC in Washington that the amateurs are lax in reporting unauthorized interference in the amateur bands. Citing the well-known Russian "woodpecker" as an example, they note that complaints to the FCC on this violation of ITU frequency allocations have dwindled to a trickle and it may be quite possible to have an assertion made at WARC 79 that the interference is nil because the amateurs themselves have stopped complaining. If you are one who has not complained because you felt the ARRL was there to protect us all and was taking care of things, then maybe you should write the League and inquire why this intrusion into the amateur bands is still going strong after more than two years. The "woodpecker" is not the only violator. The Afrikaner Net has at times been forced to shift frequency because of commercial interference. There are times when you must take matters into your own hands and quit waiting for the other fellow. The following is a full list of FCC monitoring stations and their telephone numbers. The next time you hear an intruder on the amateur bands, pick up your telephone and report it to the nearest monitoring station. Not just once, but every time.

Allegan, Michigan	(616)-673-2063
Anchorage, Alaska	(907)-344-1011
Belfast, Maine	(207)-338-4088
Douglas, Arizona	(602)-364-2133
Ferndale, Washington	(206)-354-4892
Fort Lauderdale, Florida	(305)-472-5511
Grand Island, Nebraska	(308)-382-4296
Kingsville, Texas	(512)-592-2531
Laurel, Maryland	(301)-725-3474
Livermore, California	(415)-447-3614
Powder Springs, Georgia	(404)-943-4794
Sabana Seca, Puerto Rico	(809)-784-3772
Washington, DC	(202)-632-6975
Waipahu, Hawaii	(808)-677-3954

Just because your neighbor called doesn't mean you need not call. The more reports the better.

ZS6BEE will shortly be heading out to Marion Island, ZS2MI, to relieve the present operator there. Plans call for some much needed activity after his arrival.

The FCC has extended the grace period for renewal of amateur radio licenses to five years. This means that you may regain your operator's privileges up to five years after letting your license expire without having to retake the exam. See the May *QST* for details.

A6XP, the last active station in the UAE, went QRT on February 11th and this appeared to have ended any amateur activity for the present time. The gear was confiscated and it seems the present authorities have no use for amateur radio in their country. K1DRN has been handling the QSL chores for A6XB since 1971 and has all the logs up to 0300Z on February 8th.

This may be a little after the fact, but a group of UA-types received permission to put Franz Joseph Land on the air using the call R1FJ. The operation was originally to start in mid-April, but this has been pushed back somewhat. Anyway, if you heard or worked R1FJ, you know it was FJL. If it hasn't been heard yet, then it should be at any time.

Amateur license totals at the end of January stood at 357,900 with 63,000 Novices, 68,000 Technicians, 119,000 Generals, 83,000 Advanceds, and 22,000 Extras. Amateur growth rate during 1978 was 8.4%.

RM-3317 requests that a hobby license be established adjacent to the 29-MHz band. The ARRL plans to file an opposition.

Recent check-ins to the 14225-kHz net include FB8XV, STØRK, CR9AJ, BV2B, and KA1NC. If any of these excite your blood, try 14225 kHz from 1500Z daily. The Afrikaner Net has been drawing not only from Africa, but South America, Europe, Asia, and the Pacific areas as well. This one meets at 21355 kHz from 1830Z.

The Comoro authorities have done a sudden about-face and shut down all amateur activity. Robin D68AD has dismantled his station, taken down his antenna, and is awaiting reassignment. It appears that Comoro will be joining the United Arab Republic in a steady march to the uppermost regions of the most-needed list.

K3ZJ wrote in to point out an error in the April QSL listing. HS1ABD's QSL manager is K3EST, not W1YRC as listed. We knew that all along, guys. We just wanted to see if you were paying attention.

Carl and Martha Henson, WB4ZNH and WN4FVU, reported great conditions in making some 5,200 QSOs from the Maldive Islands, mostly on twenty with some on fifteen, but precious few on 10/40 meters. They give much of the credit to 4S7EA and his friends at Ceylon Tours as well as to 4S7JD and his wife for their generous hospitality and the fact that they were there if anything was needed. QSL to Carl Henson, 8280 Chestnut Dr., Jonesboro GA 30236. Carl notes that cards for AQ7 and HQ7 will be answered okay, but cards with incorrect date and/or time will receive biting criticism in addition to QSL. (Apparently, some stations mistook 8Q7 for AQ7 or HQ7.)

That's about all for this month. I hope some of the preceding information helps you work a few new ones. If any of you take a DXpedition-type vacation this summer, shoot a few extra pictures of your exotic surroundings and send them along, either black-and-white or color.

Thanks for much of the preceding information to the *West Coast DX Bulletin*, the Long Island DX Association *Newsletter*, and *WorldRadio News*.

NOVICE CORNER

We have been asked to remind everyone to please not send cards destined to stateside QSL managers via the ARRL Outgoing QSL Bureau. These cards wind up in that manager's envelope at the bureau and then he must pay postage on it to get his own cards from the bureau. If a QSL isn't worth the 30¢ two-way postage to the one requesting it, it sure isn't worth anything to the manager. Remember to always use GMT, also called UCT or Zulu time, on QSLs sent to managers and always include a self-addressed stamped envelope (SASE) or a self-addressed envelope and IRCs (SAE) for the manager to use in sending the DX station's QSL back.

AMATEUR RADIO IN JAPAN

The following information comes from an interview between Jan Shillington N9YL and Jun Okamura JA2BJW which appeared in the Wheaton Community Radio Amateurs, Inc., bulletin which is edited by N9YL. It should greatly increase your knowledge of conditions in Japan.

Q. How many hams are there in Japan?

A. There are 355,757 stations (CB—367,633) as of December, 1977.

Q. How many classes are there in Japan?

A. Four classes—First Class, Second Class, Novice-CW, and Novice-Phone.

Q. How many DX countries has Japan?

A. Four countries—JA, JD1 (Ogasawara Island), JD1 (Minami-Torishima Island), and JD1 (Okino Torishima).

Q. What is the Japanese zone number?

A. 25 (WW contest, etc.) and 45 (ITU).

Q. How many kinds of month-

From left to right: Ernest 4S7EA, Carl WB4ZNH/8Q7AF, Martha WN4FVU/8Q7AG, and Jay 4S7JD during Carl and Martha's recent successful operation from the Maldive Islands in the Indian Ocean.

ly ham magazines are published in Japan?

A. Three kinds—JARL News, CQ Ham Radio, *and* Mobile Ham.

Q. Can you tell me the Japanese prefixes in licensed order?

A. JA, JH, JR, JE, JF, JG, JI, JJ, JK, and JL (except JD, 8J1).

Q. What is the call area of the largest number of hams in Japan?

A. JA1 has about 41% of all.

Q. What is the call area of the smallest number of hams in Japan?

A. JA9 has about 4% of all.

Q. How much is a Drake TR-7 in Japan?

A. $1,338 ($1 equals ¥195). Prices for other rigs: Mosley TA-33—$307; Yaesu FT-101—$903; Collins KWM-2A—$4666; Hy-Gain TH6DXX—$508; Trio TS-820S—$1180.

Q. Can an American operate in Japan?

A. Yes, he can, but as a member of a club station only.

Q. Can you tell me the structure of a callsign for a Japanese club station?

A. Three-letter suffix, of which the first letter is Y or Z, such as JA1YAA, JH2ZAB.

Q. Is KA in Japan a ham station?

A. No. The Japanese government does not recognize KA as a ham. JA is forbidden to QSO with KA.

Q. What are the most wanted three states of USA from JA?

A. Delaware, Wyoming, and North Dakota.

Q. In which direction does W's sig come up to JA on short path?

A. Around 40° NE.

If you are planning a trip to Japan and would like to operate under their "club" system, contact the TIARA (club?) at: TIARA, Tomigaya Grand-301, 19-5 Tomigaya 2-chome, Sibuya, Tokyo 151, Japan, or telephone in Tokyo 485-1971.—N9YL.

OSCAR DXPEDITION ANNOUNCEMENT

WB6GFJ will return to Tahiti later this summer to operate on OSCAR. The Post and Telecommunications Office in Papeete has just notified Ross that his callsign has been authorized and is awaiting his arrival in Tahiti. His callsign will be FO0FB. QSL via WB6GFJ or the AMSAT-OSCAR QSL Bureau. This year, Ross will have Modes A, B, and J (CW and SSB), but will concentrate on Mode A QSOs from Tahiti. Plans are to operate on all currently-operating satellites with Mode A capabilities. As plans firm up, we will publish exact dates, times, frequencies, and exact orbits to look for Ross on the air on OSCAR.

Part of his time will be spent helping FO8 stations get started and operating on OSCAR. Anyone with unused 2 meter converters or small CW transmitters that could be left with FO8 stations for them to use on OSCAR would be appreciated. Also, anybody that can translate OSCAR information from English into French would be most appreciated—contact Ross as soon as possible.

Presently, the plans are to be in Tahiti sometime in August or September of this year.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 4

committees suppose. When someone like me can double the attendance, that's important to know.

All during the St. Louis hamfest, people introduced themselves to me and said they had driven hours to get there and hear what I had to say. It works. Committees should look over the ham world for people who will have things to say which hams want to hear . . . and one way or another get these speakers in. All too many of the speakers are excruciatingly dull, so it isn't easy to find the hot ones.

The 2,000 chairs in the hall were almost fully occupied, with over 1,500 estimated in the audience as I talked about amateur radio past, present, and future. That's not bad for a first hamfest in St. Louis, I'd say. I didn't see any League officials at the hamfest at all . . . and the League didn't even bother to have a booth!

The hamfest committee is to be congratulated on putting on a first-rate show, having an in-

Hams drove in from over 200 miles around to enjoy this day in St. Louis—ARCH MARCH—ARCH for the famous St. Louis arch and MARCH for Midwest Amateur Radio Computer Hobbyists. This is the 73 Magazine *booth (also* Kilobaud MICROCOMPUTING*) and Sherry handling subscriptions.*

In case any ARRLers who said that no hamfest could succeed without the support of the League have any lingering doubts, here is a picture of one part of the exhibits . . . and the whole place was packed like this. The ARRL, though invited, did not even bother to run a booth at the show and the local director refused to come. No one here was interested in politics, neither pro-ARRL nor con; it was a hamfest and a joyous one. It is a pity that the ARRL has to see every amateur function as a political threat.

teresting program (other than me), getting an exhibition hall full of exhibitors, and in doing all this in just a few weeks. The ARRL said there was no way to put on a good hamfest without starting a year ahead. Balderdash.

DALLAS AND ATLANTA

So far, my commitments for talking at hamfests for the rest of this year include a barrage at Dallas in early June and at Atlanta in mid-June. I'll be giving two talks at both hamfests . . . one on amateur radio and what can be done to get it going again, and the other on how to take advantage of the incredible opportunities for making money with microcomputers. I personally intend to increase my own net worth substantially during the next year or so, *and* thousands of others can get on the bandwagon . . . once they know the secret of how to go about it.

In September, I'll be giving a talk at the Hartford ARRL Convention. I'll bet they'll hate that! Right in their home town!

NOTHING CAN GO WRONG . . . GO WRONG . . . GO WRONG . . .

Joke number 1254C, wherein the captain of the plane gets on the intercom and says, "This is flight 73X, now leaving Boston and flying nonstop to Seattle. This is the first fully-automated transcontinental flight run entirely by microcomputer. The system has been thoroughly tested and it is so dependable that it is no longer necessary for a flight crew to featherbed on these flights. Be assured that every contingency has been considered and nothing whatever can possibly go wrong . . . go wrong . . . go wrong . . . go wrong . . ."

Which brings us to the ridiculous situation we've had with trying to keep up with subscriptions. If you get many magazines, you realize that we are not alone in trying to cope with the monumental screwups which computers can aggravate. Yes, I know all about computers not making mistakes, but I also know that programmers, computer salesmen, computer manufacturers, and data-input people are capable of incredible botching and/or deceptions.

Bill Blair, of the *Country Journal*, recently devoted a full-page editorial to apologizing for subscription aggravations to readers, citing Fawcett Publications as the cause of their miseries. Our problems stemmed from Data Input Service Corp. (DISC), down near Boston . . . with a big assist from Prime Computer, Inc.

A few years ago, we handled all of the subscriptions for *73* by cutting a small mimeograph-type of stencil for each subscriber. This paper stencil was then filed in a rack by zip code and it took maybe a day or two to handle a subscription, complete with sending any desired back issues. When there was any problem, all we had to do was go to the file, pull out the stencil, and see what had gone wrong. It took maybe a couple of minutes. One girl was able to handle everything.

Obviously, such an archaic system had to be improved. We called IBM and signed on the dotted line for what they recommended. It was an IBM 403 with keypunch and card sorter. It was so big and heavy that we had to have a special support in the basement to keep the floor from caving in.

The 403 was no blessing. It took as long to punch a card for each subscriber as it had to cut a stencil . . . and longer to file the cards, which still had to be hand-filed. The 403 printer was not as fast at making labels as the Elliott paper stencil printer. Such was progress.

After evaluating the net result of the new system, which cost about twice as much as the old one to use . . . and was slower, I started looking for an outside computer service to handle subscriptions. I found one which was recommended highly by one of our advertisers (Waters Manufacturing . . . it was also a subsidiary of Waters, so perhaps their enthusiasm was not without bias), and moved our subscription list there. Within three months we were in deep trouble.

It took us several months to go back over past subscriber lists and find the well over 2,000 subscribers who had been dropped seemingly at random by the computer. This outfit, which eventually became DISC, mumbled about dirt in the tape-read heads, or something.

As the number of subscriptions and the number of problems escalated, with our response time on looking up answers for angry readers going from the one or two days when we were doing everything ourselves to two and three months with the computer service, I got antsy to get things back on home ground. That was when I started calling computer firms to see what I needed, and it was then I found that computer folk had a language all their own which I couldn't understand.

It was my attempt to cope with this language barrier which resulted in my starting *Byte*, if you remember that magazine. I eventually gave up trying to learn enough to outwit the computer salesmen and software houses and hired my own "expert" to sort out the claims and promises of the computer firms.

My expert checked out everything available and recommended the Prime 300 computer as being the best for our application. I talked with the Prime salesmen and was assured that their system would be able to handle the subscriptions for *73*, for *Kilobaud MICROCOMPUTING*, our accounting, Reader Service, prospective subscriber lists, industry lists, advertising lists and data, repeater lists, article lists, daily orders, inventory, and a few other chores . . . no problem.

By mortgaging everything right down to the paper clips, we were able to buy a Prime 300. Our expert hired two full-time programmers to write programs for handling our subscriptions. One year later, we were ready to give it a try. We were desperate to use it because things had been going from bad to worse with the outside service.

Once we had the subscriptions on our own system, the problems went from worse to total disaster. One 13-megabyte disk was not enough, said Prime, no matter what their salesmen had said. So, we bought a second drive. In no time at all, that one had bogged and clogged, and a third drive was needed immediately. I think they ran about $15,000 each, heading us for the poorhouse. When things still grunted to a halt, the diagnosis was a need for 64K additional internal memory . . . another $15,000.

The subscriptions kept the computer from being usable for anything else at all. Reader Service had to go back to being done by hand, the accounting had to be sent out to a service agency, the payroll was sent to another agency, and so it went. I finally made enough of a fuss that Prime sent a technician to see what was wrong. It was then that they discovered that the Prime operating system had no provision for reusing disk space which had been left free by expired or moved subscribers. We were heading toward a need for hundreds of megabytes at this clip. Prime eventually came up with a mod for the operating system which allowed material to be deleted from a disk rather than just be ignored.

Added to the system programming problems were troubles with keeping the equipment running. The disks were going down every few days, we had memory problems, the power supply went out every now and then, and so it went. We finally gave up trying to cope with it and went back to DISC with the subscriotions.

Today, three years into owning the Prime 300, we are able to use it for handling the daily orders, Reader Service, and a few shorter lists . . . and that's about all. Beyond that, it bogs down and little comes out. I'd estimate that the system is able to do about 20% of what the Prime people promised—tops. I've been trying to get help from Prime on this, but they are so busy building new plants and selling larger systems that they seem unable to remember their sale of three years ago.

I am no fan of IBM . . . indeed, when I had IBM come in to recommend a new computer system for us, they suggested a System 32, with floppy disks and no application programming available. I think *that* probably would have been even worse than the Prime. But there is much to be said for buying a more-popular computer system and keeping away from smaller outfits such as Prime. It is almost impossible to find programmers or data-processing people with experience on the Prime. This means you have to hire people with little or no training and send them to Prime school at your own expense. Then you have to put them to work for a year or so on a system for which you are paying (they are not cheap) and give them time to get experienced.

The computer has been much more dependable since we fired all of the data-processing people who smoked. They swore up and down that the filters on the system would keep the smoke from hurting the disks, but disk failure now is rare with no smokers around.

For a while it appeared that DISC was going to be able to cope with the subscriptions, but eventually the problems got worse and worse. Three-year subscribers were entered for one year, address changes brought duplicate, triplicate, or no copies. Requests for help went unanswered. It was a disaster. As the complaints grew, I got more and more frustrated. My circulation people daily assured me that everything was being taken care of. All letters were being answered. All missing issues were being sent. Then I found that one of our customer-service people had merely been putting problems into a box and working on the top ones. There were about three-thousand unanswered complaints built up.

I raised hell. It took about twelve full-time people to work out the problems over a period of months, but it was like building a sand castle with the tide coming in. As fast as a thousand problems were solved, the data-input people at the service bureau would create two thousand more.

We shopped around for a long time, looking for a sub-

scription service (called fulfillment). We checked each one out with several of their customers because many magazines are having serious problems with this, as reported by Bill Blair. The magazine publishing magazine, *Folio*, often has grim stories of magazine fulfillment service problems, so they are a sad fact of modern publishing life.

All this is of little consolation to the innocent subscriber who gets caught in the middle of this mess. Since I subscribe to over 200 publications per month, I frequently run into these frustrations myself. I haven't found any magazines yet which are out to screw anyone . . . the screwing is there, but not intentional. I have found the circulation departments of most magazines to be as dedicated to helping the subscriber as ours, and just as frustrated as the subscribers over the problems.

Those readers of *73* who have not been loused up by our copelessness are asked to check around to see if they have any friends who have been victimized. Tell them that we really think we have things in hand at last. Our new agency, FAI, in New York, seems to be getting good marks from the other magazines they handle and have been getting our problems squared away quite satisfactorily for the last two months.

If you have written about a subscription problem and have not heard from us yet, you will receive a customer service report form in the next two to three weeks . . . this will speed up the handling of all problems and questions. Everyone here wants to have every subscriber happy and fulfilled. Please pass the word around at your club and over the air and let's make sure that everyone is made happy.

DEALING WITH THE FCC

The recent screwing of the hams by the FCC came as no surprise to those who are familiar with the way this government agency works. The real responsibility for the utter failure of the amateur community to come out of the situation with reasonable rules has to lie with both the ARRL and the ham industry.

The League, by convincing most amateurs that amateur radio is well represented by the ARRL, has discouraged any initiative by either individuals or clubs. Indeed, the ARRL has done all it can to discourage any individual approach to the FCC by amateurs and clubs. The net result of this is that when the ARRL fails to provide representation, there is none by anyone, so the FCC goes right ahead without any guidance and terrible things go wrong.

The FCC has been dealt with once in the last few years with great success. I hate to make a big deal out of this, but the results of this effort were so outstanding that it should not be swept under the table. I don't recall ever seeing even the slightest mention in *QST* of the ham/FCC meeting which brought about the complete turn of events with the FCC and the remarkable changes in repeater regulations, deregulation of amateurs, and a great many other changes.

Here's what happened. Amateurs in general were happy with the lack of restrictions on the use of repeaters and had adapted to the problems this lack of restrictions had caused by getting together and working out unofficial rules. We set up coordinating groups, repeater councils, got a national coordination plan working, etc., all without any help from either the FCC or the ARRL.

A few amateurs insisted that we *must* have FCC regulations for repeaters. Years later, the FCC suddenly acted by announcing brutally-restrictive rules and forcing the generation of incredible amounts of paperwork . . . to no one's benefit. The ARRL refused to do anything about the situation, partly because they had very little contact with repeaters and partly because they didn't want to anger anyone at the FCC.

Amateurs responded to the new rules by filing hundreds of petitions for reconsideration of the rules. Prose Walker, the chap in charge at the time, responded by throwing the whole lot in his wastebasket. I could see that we were going to get nowhere this way, so I decided it was time to do something about it.

Having been strongly instrumental in the nationalization of repeater frequency pairs via my *Repeater Bulletin* (monthly newsletter to repeater groups) and FM symposiums around the country which *73* sponsored, I contacted repeater groups and got them to send representatives to Washington to testify before the FCC. I set up the hearing and got the seven FCC Commissioners and the repeater group representatives into a hearing room and orchestrated a convincing discussion of the need for deregulating amateur radio. The ARRL, by the way, was asked to help with this and flatly refused. Right after the hearing, the League counsel took some of the visitors out to lunch and explained patronizingly that this sort of approach would not work . . . a waste of time.

It did work. The FCC Commissioners listened and were impressed. Wiley became chairman of the FCC and implemented the deregulation of amateur radio which we requested. The hearing was in January, 1974, and soon after that the restrictive repeater regulations began to be changed. Prose was "retired" and amateur rules improved enormously.

So what went wrong recently?

When the amateur industry gathered to testify before the Commissioners regarding ten meter linears, there was none of the cooperation which I had been able to bring to the 1974 hearing. I had gotten my group together the day before the hearing and we had gone through just what we wanted to get across, how best to do it, who should discuss what and answer questions on it, etc. We had our act together.

This time there was no act at all. ARMA, the manufacturer's association, got people from industry in to testify, but the ARRL's council was there and refused to cooperate with ARMA. Several of the manufacturers refused to cooperate with ARMA. The result was that the ARRL testimony, which went on interminably, took the wind out of the sails of the ARMA representative. The whole presentation was fumbling and lacked direction. Worse, no one had any concrete suggestions for anything to replace the FCC plan. The FCC didn't want to know what was wrong with their plan, they just wanted to do something. Without any alternative to offer, hams lost the battle completely.

I sat in on the discussions before the testimony and tried my best to get the manufacturers to provide a clear and coherent approach to the situation, complete with an easy out for the Commission. I got nowhere with this. I have tapes of these meetings and the FCC testimony if any historian wishes to review the sorry event at some later date.

After the fumbling and often emotional testimony by the ARRL and the industry, offering little constructive to the FCC, in came the EIA (Electronic Industries Association) representative. He had his act together. He got up, spoke for about five minutes, telling the FCC they were right, just exactly what they wanted to hear, and sat down. He won the day hands down. The score: CB—1, hams —0.

Sad to say, I see not even the slightest hint that either the ARRL or the ham industry has learned anything from this incredible debacle. ARMA is talking about paying a professional lobbyist in Washington, someone who not only is not a ham, but who also doesn't even know anything about amateur radio! I agree that we desperately need some strong representation in Washington—that's where the action is. But I disagree on grasping at straws. We need an experienced ham, possibly retired, who can spend the time to keep the FCC acquainted with what amateurs need in the way of changed rules. He could also keep in contact with key congressmen and senators to help put pressure where it is needed, when it is needed.

We also need to get our act together and organize hearings before the FCC when we need them. These hearings should be carefully planned and run. The Commissioners have a lot bigger pots to stir than amateur radio, so the more of their work we can do for them, the more cooperation we will get. We should try to remember that.

You can bet that if anything does get going in the way of an International Amateur Radio Lobby, a great deal of the push will be in Washington, where the power is. There is no reason why amateur radio should permit itself to be pushed around. We can't depend on the ARRL for these things, as we have seen all too clearly. If the League ever does decide to do something affirmative, then we can support them . . . but why support a vacuum?

SEEK FAME AND FORTUNE

Well, fame anyway. Getting published in *73* does often seem to pay off in wondrous ways. I'm talking about a lot more than just the recognition you get at the club or in contacts over the air—which can be heady enough. Many authors have written to tell me about doors that an article has opened for them . . . interesting jobs, consulting, etc.

Getting published still has the effect of making you an "expert" on a subject. It then follows that some firm somewhere has a need for such an expert and you find yourself in demand.

In addition to reflecting in the prominence a published article brings, there is the satisfaction of knowing that you've provided both education and entertainment to tens of thousands of people. How many times in your life can you reach out and touch that many people?

If all that doesn't move you to a typewriter, then let's get crass about it and point out that *73* pays hard cash for articles, and a lot more than any other ham magazine. Heck, one magazine seems to pay only if you get a lawyer to sue them for the pittance they promise. *QST* not only doesn't pay one cent for the articles they publish, but also you don't even get word on when your article will appear or any chance to even see it before publication! No wonder they

have so little of any significance.

With *73*, you get paid upon acceptance, not upon publication. This means you get paid right up front. Then, when your article is set in type and set up for publication, you will get a page proof of it to check over for any errors. You get to see it about the way it is going to appear in the magazine. And when it comes out, your call will be right there on the cover of the magazine.

One other thing . . . *QST* has a practice of rewriting just about every article. This means that your golden prose will be put through the meat grinder by some hack and the resultant mush will be attributed 100% to you, even though you haven't been given a chance to defend yourself. There are an awful lot of furious ex-*QST* authors. Have you noticed how few regular contributors there are in *QST* other than their poorly-paid staff? How many paid-staff articles do you find we have to use to pad out *73* to a reasonable size? And we publish about three times as many pages of articles as *QST* per month.

Another magazine strategem you want to watch out for is the small down payment, with the rest upon publication. This is a gem. It saves the magazine a bundle, obviously. It unfairly ties up the author, but without anything significant in pay. I understand that both *Byte* and *Interface Age* use this author-screwing system. And suppose they decide not to ever publish the article at all? You're helpless. So, for a few bucks, a magazine can keep articles which they have no intention of ever using from being submitted to competitor magazines.

It does take a substantial investment in articles to keep up a magazine inventory. For instance, at around $50 a page for *73*, this means that the hundred pages of articles in an issue will tie up about $5,000. We carry an inventory of perhaps six months in articles normally . . . about $30,000 or so.

What kind of articles are needed? Of course, the most-read articles are generally those about small construction projects. We're open for anything at all . . . antennas, gadgets, complete receivers, transceivers, test equipment, shack accessories, repeaters, microcomputers with a ham accent, autocall systems, anything on DXing, DXpeditions, humor which will make *me* laugh, good cartoons (no amateurs at this, please . . . except radio amateurs), club activities, club projects, stories of transmitter hunts, interviews with famous hams, reviews of new equipment . . . it is endless.

How many antenna articles can we publish? Hundreds . . . anything new and interesting will get a thousand hams heading for their roofs. Perhaps you've hooked a computer up for some CW processing. Antenna aiming? Digital circuits of almost any kind are read with great interest by most readers. I look through the ads and wish we could get good interesting articles on every piece of new equipment I see. Sure, I wish I could be the one to use the gear and write it up myself, but I'm already spread much too thin, so as a practical matter, I'd like to see reader evaluations. Why not help pay for your equipment that way?

Before you get a lot of ideas about conning manufacturers for free gear to be written up . . . no way. I flatly refuse to give anyone any prior agreement to publish anything. I want people who have spent their hard-earned money to cash in on this, not some sharpy on the con. Manufacturers, please go with me on this: Unless you hear from me personally about someone going to test something, do not get suckered into someone saying they are going to write an article on the equipment and therefore should get it free or for a discount. if I hear about it, no deal.

RTTY . . . I want a lot more material on RTTY. I want it on OSCAR and equipment for using OSCAR. I want updates on new stuff for SSTV. Let's keep it going. How about more info on TV satellite reception? How about weather satellite information? There are so many things going on that I don't understand the chap who calls up and says he would like to write an article but doesn't know what to write about.

FEBRUARY WINNER

For the second time in four months (he was also our November winner), Dr. Ralph E. Taggart WB8DQT has walked away with our $100 "Most Popular Article" check. Our readers used their Reader Service card ballots to select "Attention, Satellite Watchers!" as their favorite article in the February issue.

Amendment of Rules Concerning the Amateur Radio Service to Permit the Acceptance by Any Commission Office of Code Credit Certificates

AGENCY: Federal Communications Commission.

ACTION: Order (rule amendment).

SUMMARY: The Commission amends § 97.25 of its rules regulating the amateur radio service to permit the acceptance by any Commission office of Code Credit Certificates. Certificates are issued to applicants for amateur radio operator licenses who have completed the telegraphy elements of their examinations but fail the written elements. This action is taken to lessen the burden on those applicants who wish to complete the examination at an office other than the one at which the telegraphy portion was taken.

EFFECTIVE DATE: April 20, 1979.

ADDRESS: Federal Communications Commission, Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT: Mr. J. B. Johnston, Private Radio Bureau, (202) 254-6884.

SUPPLEMENTARY INFORMATION:

In the matter of amendment of §§ 97.3 and 97.25(b) of the Commission's Rules; Order.

Adopted: February 22, 1979.

Released: April 6, 1979.

By the Commission.

1. By an Order released on June 7, 1978, effective June 16, 1978, the Commission amended §§ 0.314, 1.922 and 97.25 of its Rules to provide for the issuance of Amateur Code Credit Certificates by the Engineer in Charge at each of its field offices. Certificates are issued to applicants for amateur radio operator licenses who successfully complete the telegraphy element of their examinations but fail the required written element. Section 97.25(b) currently provides that upon presentation of the Certificate to the Commission within one year of the date of its issuance, the applicant will be given credit for the telegraphy element at the speed listed. The purpose of the Certificate is to allow an applicant to receive his/her amateur license upon successful completion of the remaining examination element(s) without having to retake the telegraphy test.

2. Section 97.25(b) currently provides that an Amateur Code Credit Certificate will be honored only at the Commission office which issued it. This restriction was intended to allow Commission personnel to validate the authenticity of certificates presented for credit. However, it has also imposed a hardship on some applicants who wish to complete their examinations at an office other than the one at which they took their telegraphy test. Thus far, there has been no problem with attempts to falsify Certificates. Interim Amateur Permits and Temporary Radio Operator Authorizations may also be presented to gain examination credit toward higher classes of radio operator licenses. These documents are accepted at any Commission office and their authentication at offices other than the issuing one has not been difficult. As it appears that the more restrictive acceptance of Code Credit Certificates is unwarranted, the Commission is herewith amending § 97.25(b) to delete this restriction. Further, in order to formalize and clarify the criteria utilized for the issuance of the Certificate, the Commission now amends § 97.3 to include a definition of "Amateur Code Credit Certificate," and § 97.25(b) to specify the conditions under which such Certificates are issued.

3. As these amendments serve to clarify Commission procedures and to eliminate an unnecessary restriction, the Commission, pursuant to Section 553(b) of the Administrative Procedure Act, finds that prior public notice and the receipt of comments are unnecessary. Additionally, in order to expeditiously eliminate any confusion and inconvenience now caused to those taking amateur radio operatpr examinations, the Commission, pursuant to § 553(b)(3) of the Administrative Procedure Act, finds that it is desirable that these amendments be made effective with less than 30 days notice.

4. Accordingly, IT IS ORDERED, effective April 20, 1979, that Part 97 of the Commission's Rules and Regulations IS AMENDED as shown below. The authority for this action is found in Sections 4(i) and 303 of the Communications Act of 1934, as amended. For further information on these Rule changes contact Mr. J. B. Johnston, Personal Radio Branch, FCC, 1919 M Street, NW, Washington, DC 20554, Tele: (202) 254-6884.

(Secs. 4, 303, 48 Stat., as amended, 1066, 1082; 47 U.S.C. 154, 303)

Federal Communications Commission.

William J. Tricarico,
Secretary.

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended as follows:

In § 97.3, a new paragraph (aa) is added as follows:

§ 97.3 Definitions.

* * * * *

(aa) *Amateur Code Credit Certificate.* A certificate issued to applicants for an amateur operator license evidencing successful completion of a telegraphy examination element.

In § 97.25 paragraph (b) is amended to read as follows:

§ 97.25 Examination credit.

* * * * *

(b) Amateur Code Credit Certificates (FCC Form 845) will be issued by the engineers in Charge of FCC offices to applicants for amateur operator licenses who successfully complete telegraphy examination elements 1(A), 1(B) or 1(C), but who fail the associated written examination element(s). Upon presentation of a properly completed Amateur Code Credit Certificate, the FCC shall give the applicant for an amateur radio operator license examination credit for the code speed listed on the Amateur Code Credit Certificate. An Amateur Code Credit Certificate is valid for a period of one year from the date of its issuance.

Ham Help

I have a basin with four ultrasonic transducers affixed to the underside. I would like to get in touch with someone who has a circuit diagram and instructions to build an ultrasonic cleaner with a basin such as mine. I would also like to know how to determine the resonant frequency of these transducers and whether they must all be driven in phase.

will be June 10, 1979. For information, contact Henry Wener WB2ALW, 53 Sherrard St., East Hills NY 11577, or phone (516)-829-5880 days or (516)-484-4323 nights.

CHELSEA MI
JUN 3

The Chelsea Swap 'n Shop will be held on Sunday, June 3, 1979, at the Chelsea Fairgrounds, Chelsea, Michigan. Gates will open for sellers at 5:00 am and for the public from 8:00 am until 3:00 pm. Admission is $1.50 in advance or $2.00 at the gate. Children under twelve and non-ham spouses are admitted free. Talk-in on 146.52 and 146.37/.97. Proceeds will benefit the Dexter High School Radio Club and the Chelsea Communications Club.

STEVENS POINT WI
JUN 3

The Central Wisconsin Radio Amateurs, Ltd., will hold its swapfest picnic on Sunday, June 3, 1979, starting at 10:00 am at Bukolt Park, Stevens Point, Wisconsin. There will be a picnic area, refreshments, equipment sales, and prizes. For information, write to Frank L. Guth W9BCC, Secretary-Treasurer, Central Wisconsin Radio Amateurs, Ltd., 1632 Ellis Street, Stevens Point WI 54481.

The Jacksonville Hamfest Association is pleased to announce the 1979 Jacksonville Hamfest and ARRL North Florida Section Convention to be held on August 4-5, 1979, at the Jacksonville Beach Municipal Auditorium, Jacksonville, Florida. The location is just one block from the beach, where U.S. 90 meets the sea.

Advanced registrations are available at $3.00 per person from R. J. Cutting W2KGI/4, 303 10th St., Atlantic Beach, Florida 32233. Price at the door will be $3.50.

A large indoor swap area will be featured, with advance table reservations available for $5.00 per table per day from Robbie Roberts KH6FMD/W4, 10557 Atlantic Blvd., #31, Jacksonville, Florida 32211. Information on exhibitors' booths and space are available from the same address.

Other features and programs include statewide organization meetings on such topics as traffic nets and MARS, a microprocessor seminar, a solar power demonstration, a DX "pileup" contest, a hidden transmitter hunt, an OSCAR forum, ARRL forums, emergency preparedness programs, DX and contest presentations, antenna and technical seminars, and much more.

More general information may be obtained from JHA, 911 Rio St. Johns Dr., Jacksonville FL 32211.

MT SINAI LI NY AUG 5

The Radio Central Amateur Radio Club will hold its "Ham-Central" on Sunday, August 5, 1979 (rain date is August 12, 1979), at the Mt. Sinai Elementary School, Rte. 25A, Mt. Sinai, Long Island, New York. Admission for sellers is $3.00 per tailgate space and $1.50 for buyers, with XYL and children under 12 free. Monies are to be used for Radio Central and the St. Charles Hospital Repeater. Doors will open at 7:00 am for sellers and 9:00 for others. They will close at 4:00 pm. Featured will be antenna advice with Art and Madeline Greenberg, a Novice table, great food, a CW contest, an ARRL table, a special event of a fly-in by the Suffolk County Police Dept. helicopter, and a Radio Central Club table. Talk-in on 146.52 WA2UEC and 144.71/145.31 K2VL. For information, call Joan Longtin at (516)-924-8438 or Robin Goodman at (516)-744-6260, or write Radio Central, "Ham-Central," PO Box 680, Miller Place NY 11764.

SALEM OH AUG 5

The second annual Salem Area Hamfest will be held on August 5, 1979, from 9:00 am to 3:00 pm at the Kent State Salem campus, Salem, Ohio. Tickets are $1.50 in advance and $2.00 at the door. Inside tables are $5.00 with space for your own table at $2.00. Flea market space is $1.00. There will be air-conditioning, a wheelchair ramp, free parking, refreshments, and prizes, consisting of an Atlas RX-110, TX-110, and a PS-110. Talk-in on 146.52. For details, write Harry Milhoan WA8FBS, 1128 West State, Salem OH 44460.

LEVELLAND TX AUG 5

The Hockley County Amateur Radio Club and the Northwest Texas Emergency Net will sponsor their 14th annual picnic and swapfest on Sunday, August 5, 1979, at the City Park, Levelland, Texas. A $2.00 registration is requested but not required. Registration begins at 8:00 am and lunch will begin at 12:30 pm with a bring-your-own-picnic-basket lunch. There will be swapping all day with tables provided. Talk-in on 146.28/.88.

GLENN MI AUG 5

The Black River Amateur Radio Club will sponsor its 26th annual VHF Picnic and Swap 'n Shop on Sunday, August 5, 1979, at the Allegan County Park, Glenn, Michigan. Take Interstate 196 north of South Haven, Michigan, to the Glenn Exit. Door prizes will be awarded. Bring the family and a picnic basket (no lunch will be provided on the grounds) to enjoy the beach and playground. Talk-in on 147.90/.30 and 146.52. For information, contact Ed Alderman WB8BNN, RR#2, Box 98AA, Bangor MI 49013, or phone (616)-427-8830.

ANGOLA IN AUG 5

The Steuben County Radio Amateurs will hold their annual F.M. Picnic and Hamfest on Sunday, August 5, 1979, at Crooked Lake, Angola, Indiana. There will be prizes, picnic-style barbecued chicken, inside tables for exhibitors and vendors, and overnight camping (fee charged by county park). Talk-in on 146.52 and 147.81/.21. Admission is $2.00.

MUNCIE IN AUG 11

The Delaware Amateur Radio Association will hold its 2nd annual hamfest on Saturday, August 11, 1979, starting at 7:00 am, at Springwater Park, County Roads 300 E. and 100 N., Muncie, Indiana. Tickets are $1.50 in advance and $2.00 at the gate. Reserved table space is $1.00 per table with no extra charge for outside space. There will be hourly drawings from 9:00 am until 3:00 pm, with the grand prize of a Tempo SYNCOM S1 being drawn at 3:00 pm. Second prize will be a HAM III rotor. Talk-in on 146.25/.85 and 146.52/.52. For information or tickets, send money and an SASE to DARA, PO Box 3021, Muncie IN 47302.

LEXINGTON KY AUG 12

The Bluegrass Amateur Radio Club will hold its annual Central Kentucky Hamfest on August 12, 1979, at the Fasig-Tipton Sales Paddock, Newton Pike, Lexington, Kentucky. The program will include grand prizes, hourly door prizes, manufacturers' exhibits, an indoor/outdoor flea market, guest speakers, and forums. For information, contact the Bluegrass Amateur Radio Club, Inc., PO Box 4411, Lexington KY 40504.

PETOSKEY MI AUG 18-19

The Straits Area Radio Club will hold its Swap 'n Shop and hamfest on August 18-19, 1979, at Petoskey Middle School, State and Howard Streets, across from the Catholic church and post office, Petoskey, Michigan. There will be a donation of $2.00 at the door. Table space is also $2.00. Refreshments will be available. There will be a swap and shop on Saturday from 9:00 am to 4:00 pm and on Sunday from 9:00 am to 12:00 pm. Prizes, a ladies' program, and seminars at 11:00 am and 2:00 pm on Saturday will be featured. A banquet at the Holiday Inn on Saturday at 7:00 pm will have Mellish Reef DXpeditioner Bob Walsh WA8MOA as guest speaker. Banquet tickets are $7.50 and are limited to 200, sold in advance only. For full information and lodging, send an SASE to Bill Moss WA8AXF, 715 Harvey Street, Petoskey MI 49770, or phone (616)-347-4734.

ST. CHARLES IL AUG 26

The Fox River Radio League will hold its hamfest on Sunday, August 26, 1979, at the Kane Co. Fairgrounds Exhibition Hall, St. Charles, Illinois. Tickets are $1.50 in advance and $2.00 at the gate. For information, contact Martin Schwamberger WB9TNQ, 1051 Northfield Drive, Aurora IL 60505.

BEREA OH SEP 23

The fourth annual Cleveland Hamfest will be held on Sunday, September 23, 1979, at the Cuyahoga County Fairgrounds, Berea, Ohio. The hamfest will be an all-indoor operation. There will be 10-foot booths available with an 8-foot table and two chairs for $30.00.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

DAYTON

Despite the rapid growth of the Atlanta Hamfestival, Dayton pulls 'em in in greater numbers every time. It's gotten so big that it is difficult to see everyone there. No, it's impossible. Whether they have 15,000 or 20,000 in attendance is irrelevant—it's too much to handle.

I had not really intended to get to Dayton this time, feeling that I would do better to spend the four days involved working on Instant Software and a new publishing project. But I began to waver just a bit when they called up and wanted to know where they could reach Jean Shepherd K2ORS in order to get him to entertain at the banquet. Then they asked if I would be available to speak on the microcomputer forum . . . and I gave in.

Shep was outstanding, as usual. I think they had well over 1,500 at the banquet, and he had them in stitches. The banquet was nice . . . grilled hockey pucks, I think. I wasn't sure. The potato was good, which is more than I can say for a lot of restaurants . . . and the company was fine. Most of the entertainment was a bore . . . some local group singing and dancing . . . unfortunately none of them were singers or dancers. That went on incredibly long. The MC was excellent . . . he introduced the two hundred or so people at the head table in a minute and a half, making some very entertaining comments as he went along.

The Dayton crew has been at it for years and they are certainly professional about it. There are few glitches in the Hamvention.

The crowds seemed to be down a bit this year—no one knows why. I heard rumors that they clocked in 14,000, compared to 19,000 last year. The aisles were easier to traverse. Other later reports put attendance at 17,000. Big deal . . . that's numbers. I talked with exhibitors, and sales were the best ever, no matter how many were there. Some dealers went home with over $50,000 in sales for the three days.

Despite long-term delivery delays promised by Drake, I understand that dealers were really loaded up with Drake gear for the show . . . which brought prices down to perhaps $5 or $10 over cost on the big gear. While this is hard on the dealers, it is a bonanza for the rest of us. All HTs were selling well, too. I don't think a single dealer went home with an HT in his truck. The showing of the first prototype of the new Yaesu programmable HT helped convince dealers that long-term stocks of the more traditional HTs would not be prudent. It's getting time to liquidate HT crystal stocks.

Swan showed their new line of transceivers and wowed everyone. Their microprocessor-controlled units will be in short supply for a long time. The Japanese are going to have to work a little harder to keep their large share of the US market.

But long after the new ham gear and the acres upon acres of flea market fade into fuzzy memory, the Jean Shepherd entertainment at the banquet will live on in memory. Long after the old rig we bought off a flea market truck that chilly Saturday has been auctioned off at a local hamfest, we'll remember Shep and his problems with the Texas kilowatt on 7182 kHz back in the '30s. "Doesn't that sonofagun ever sleep?"

ARMA

The most recent meeting of the Amateur Radio Manufacturer's Association came the night before the Dayton Hamvention and was sparsely attended, considering that almost 250 firms run ads in any one month in the ham magazines.

A representative from the Electronic Industries Association was there to try to convince the ham industry that they might do better to join the EIA rather than fritter around with ARMA. It was noted that only one ham manufacturer is presently a member of EIA, and that one admitted discovering the membership with some surprise, a sort of bonus for their CB affiliation.

I don't think I helped that project as much as I might have when I reminded everyone that we had heard this same story ten years ago when Bob Waters lured the ham industry away from a ham manufacturer's association and into the EIA. The ham industry was in the same division as the CB industry, and thus when it came to any conflicts between the two (and there were beauts, like 220 MHz), money talked and the ham industry seemed to get a deaf ear.

The costs of joining the EIA are not insignificant. It would cost *73* about $2,000 per year to belong, with few (if any) benefits which I could pin down. And then, if any special projects for lobbying came up, the cost of them would be on top of the two thou. Someday, I'd like to have a general idea of how much Hy-Gain and Johnson put into the pot to get more CB channels on eleven meters and the 220 MHz band for CB. Both of those projects were bummers, incidentally. The eleven meter expansion project resulted in the serious wounding of CB and cost the industry billions. It sank Hy-Gain.

It was noted that ARMA had not been able to decide on anything and follow it through with success. The effort to stave off FCC actions on linear amplifiers was an abject failure. I feel that this total defeat was primarily due to the lack of support of ARMA by some of the larger firms in the ham industry, the back-stabbing (to put it politely) by the ARRL, and the lack of strong leadership in ARMA to put together a program with which to fight the

FCC and win.

One of the more serious problems facing any industry association is the seeming preference for the death of amateur radio over accommodation between the US manufacturers and importers of Japanese (called "foreign") equipment. I can understand the emotions involved, particularly when you consider that somewhere around 70% of the ham gear being sold is being imported from Japan. I've heard repeated claims that the Japanese are selling this ham gear at a loss here in order to destroy the US manufacturers. I'd sure like to see some proof of this contention.

On the surface of it, the high sales of Japanese equipment seems to be the result of a lot of advertising, excellent design, good marketing, and factors such as this. The Japanese have some unfair advantages, I'll admit, in that they have about 400,000 hams in Japan as a market that is virtually closed to our manufacturers. With about double the market for ham gear, they can afford to spend more on design and run larger production runs . . . which means lower costs.

Then there is the matter of Japanese productivity vs. that of the US. A recent article in *Fortune* pointed out that the US has been down toward the bottom of the list in worker productivity improvements. The Japanese have been building new and more automated plants, while our unions and government have been making it almost impossible for us to do the same, thus forcing dealers to sell imported equipment which has more features and costs less.

There have been some strong moves to turn this around. Swan has stopped importing their equipment and is now making everything here in the US. Their new line of transceivers is going to have a strong effect on the market, for they are taking advantage of microcomputer technology. But other US manufacturers have been complacent, telling dealers that they are so busy with other things that ham gear will be six months or more back-ordered. And one major firm which has been making a big deal out of hams buying American has some very clearly indentifiable Japanese parts in its new rig.

Some of the US problems undoubtedly could be cured if we could get the government out of the act. I talked with one manufacturer recently who had had his plant closed down by OSHA because they found a fire escape support column which was painted. It seems that they could not inspect the column for any possible cracks . . . so everyone had to be sent home until the paint could be removed from the fire escape column.

OSHA seems to be the cause of the recent semiconductor plant shutdown which caused incredible consternation in the entire electronics industry. The early estimates are that much over $10 billion was lost as a result of this unnecessary action. Some 20¢ chips were being bid up to $5.00 and more by contractors frantic to finish contracts on time or by manufacturers being pressured by customers for delivery.

I doubt if they are having nearly as much government harassment in Japan . . . and this means that they can be more competitive with us. If you read much about Japan, you know that workers take their jobs very seriously and are dedicated to their employers. The excesses of many industrialists of a hundred years ago spawned a strong union movement in the US, and some of the ramifications of that have not been helpful in making us competitive with other countries. The strong union positions in England have been a powerful factor in keeping that country from being seriously competitive with much of the world.

In the microcomputer field, no other country has been able to provide any serious competition for the US. You can bet that the Japanese microcomputer makers have been over here, sizing up the market, but they haven't been able to do much about it. Between our technological advances and the dollar/yen situation, US firms are getting into better positions to give the Japanese a run for their money. Where we are not being held back by union restrictions on modernization and excessive government regulation, we can raise hell with imports.

Well, getting back to ARMA, the suggestion was made that instead of trying to represent the industry, getting involved with battles with the FCC, or trying to help our WARC position, it be made more of a social club . . . perhaps with an industry friendship dinner during the more important hamfests and conventions. If the group is afraid to tackle anything more meaningful than that, then let's have dinner meetings and eat. That's better than protracted meetings hassling over bylaws, dues, and elections, which are just an enormous waste of time and of little interest.

There is one point of history that I would like to clarify since it seems to already be in the process of being rewritten. It was mentioned at the ARMA meeting that the opinion about trying to do something to help the amateur radio position at WARC was about evenly split. I might remind ARMA that the motion to tackle this project was made by Tom Gentry of Icom—it was carried with one and only one negative vote.

I recognize that the eventual scuttling of the project, which I attribute to *Ham Radio* magazine, calls for a distribution of

These issues may be purchased at $8.50 for 5 of your choice (order #STO500), $14 for 10 of your choice (# ST1000), or $25 for 25 of your choice (#ST2501). Include $1 for postage and handling, and send your order to 73 Radio Bookshop, Peterborough NH 03458.

LETTERS

MEMORIES

I was reading my March issue of *73* and noticed your story of the trip we took to Europe in October, 1963. I always felt that the idea of the Institute of Amateur Radio was a very good one and that hams getting to know hams through group tours to other countries was an excellent way of promoting amateur radio.

I am a holder of a lifetime subscription to *73* (yes, I was one of the lucky ones who subscribed in Miami back in '61 or '62), and I have followed you through your editorials. Many times I started to write and tell you how much Anna and I enjoyed the trip, but somehow I never got around to it.

Do you remember your miniature greyhound jumping off the bed and breaking its leg? Or Annora Todd yelling that she wanted to get off at "Arts and Meters" underground station in Paris? Wasn't the cannelloni good at the restaurant in Rome where we went with you one evening and ate in the open-air section? Do you remember when one of the single guys had to double up in the room with the gal in the red coat and her husband? I can't remember her name, but in a crowd we would all say, "Follow the gal in the red coat."

Well, I've finally gotten around to telling you (after all these years) how good I think your idea was and how great the trip was. I have gone many places since then, but never had one-tenth the fun we all did on that momentous trip to Europe by *73* hams. If that trip could ever be duplicated and it leaked out how much fun it was and how interesting it was to meet hams from other countries, you would have to form a full-time travel agency.

I have recently retired from practicing dentistry, and Anna and I moved here to the mountains of western North Carolina from Miami, Florida. Good luck, Wayne, and keep up the good work.

Lamon L. Whiddon K4MHY
Boone NC

It was January, 1961, and you were Life Subscriber #1. I remember it well! The Italian greyhound was named Petite Chienne because that's what everyone called her when we got to Paris. The Rome restaurant was the Tres Scalini and it is still there and superb. I often look at the slides and relive that fantastic trip.—Wayne.

Somehow I was propelled to open the March copy of *73* and I read Never Say Die.

My husband has been dead a year and I had not opened any of his ham magazines until today. As one of the XYLs on that 1963 trip to Europe, I want to thank you for renewing all those wonderful memories.

It would be wonderful to be in contact with the travel group again.

Annora Todd
222 W. Hawthorne St.
Aurora MO 65605

SCHOLARSHIPS

High-school graduates who plan to enter college this fall and who are licensed amateurs may be eligible for one of the $250 scholarships offered by the Atlanta Radio Club. If you qualify, write to the ARC Scholarship Fund, PO Box 77171, Atlanta GA 30357.

Philip J. Latta W4GTS
Marietta GA

ABSURDITY

I feel that the idea of each ITU country having one vote each at WARC is absurd.

Although some people have expressed discontent at the very idea of one country having more say than another, citing it undemocratic, I see it as just the opposite. I see it undemocratic when a handful of radio users have the same vote as millions. This is totally unreasonable for the millions of radio users, since the more operators there are, the more air space is required.

The only truly fair way on which to base votes is on radio population. Because it is not going to change, I feel the US should drop out of the ITU. Many countries play the ITU game during conferences and then disregard the decisions made afterwards, anyway.

William D. Matteo WB2IVI
Toms River NJ

WPIX

From time to time, you mention your television career. With this in mind, I thought you might be interested in the accompanying picture which shows a young (1948) Wayne Green, hair and all, behind a WPIX RCA-TK 10 camera.

I believe the man at the piano is Sigmund Spaeth, who had a program called "The Tune Detective."

I am sure your loss to TV was a gain for amateurs.

Otis Freeman
WPIX, Inc.
New York City NY

Thanks, Otis! Sure, I remember Dr. Spaeth and his program . . . and little things like the night I did the Woody Woodpecker call for him on camera. I remember the Gloria Swanson show, too, with Zasu Pitts and a lot of other old-time stars. Those were fantastic times. The hair? Heck, my father has more hair than I do . . . so did his father, right up until he died . . . but then they didn't have the aggravation of my first wife.—Wayne.

SURPLUS

I just read an article in one of the back issues of *73*. The issue, Feb., '78, had an article by James C. Chapel W9HDA, entitled "Surplus Adventures—pound foolish!" He didn't feel he could trust a company to ship a signal generator to him from a government surplus outlet. Well, this definitely points out a need of hams.

I want to become a ham but suffer from a pecuniary deficiency. Since I work at the Ogden depot, which is a major electronics surplus outlet in Utah, I think I can benefit all those out there who wish to purchase this equipment and who do not wish to suffer expensewise in the process! In short, I offer, for a reasonable fee, to ship what they wish from Ogden to wherever they may desire.

My background consists of thirteen years in electronics, the last 6 months of which have been as a quality control inspector in the same field. I could, most likely, even inspect the item they wish to bid on, given enough lead time. Not only will all the hams out there benefit, but maybe I'll finally be able to join the fraternity.

If I should thrive at this, I shall definitely make it a business and we'll all benefit because then I'll be able to afford to advertise in your superb magazine. Until then, I shall have to rely on your largess to print this in your next Letters column. If anyone out there is interested, please have them include an SASE.

HOT CHIHUAHUA

I am returning to the frontiers of Texas again, this time backpacking in the arid wilderness mountains of the Chihuahuan Desert. Please publish the particulars of the expedition so that more experimental NBVM stations may participate. One of the following mountain ranges will be selected for a base camp above the desert floor where temperatures will be more tolerable while operating: Chisos, Davis, Glass, Guadalupe, Christmas, Solitario, or Caballo Muerta.

We will carry in all water, radios, a solar array, food, and shelter. We will be operating Sunday, July 1, through Saturday, July 7, with a two-Watt output transceiver in NBVM, SSB, and CW modes on all HF bands. In addition, we will carry a Tempo S1 2-meter FM hand-held (1.5 Watts). There are a few VHF

Looking West

Bill Pasternak WA6ITF
24854-C Newhall Ave.
Newhall CA 91321

Mike Davis WD6FFV of Torrance, California, is a real live 13-year-old hero. On the evening of April 24th, Mike's parents gave him permission to stay up late in order to indulge in a bit of his favorite pastime: operating his station and hunting DX. Everyone else in the house was asleep as Mike searched the band looking for the western Caroline Islands. At about 1:00 am on the morning of April 25th, Mike happened across a QSO between someone on a fishing boat off the coast of Jamaica and someone in New Zealand. Conditions between the craft (later identified as the fishing vessel *Carmen*) and ZL-land were poor at best, and the information exchanged showed that an emergency existed. When those aboard the *Carmen*, identified as the boat's owner Leonard Hutchinson and crew members David Dalquist and Sergio Perez, again sent out a "Mayday" call, Mike responded, obtained their latitude and longitude, and phoned this information to the Long Beach Coast Guard station, which in turn relayed same to Miami. The situation was this: The *Carmen* was some 60 miles off the coast of Jamaica. It had been severely battered by high winds and rough seas and was taking on water. Those aboard knew that the craft would sink; they needed immediate rescue. Mike spent the next 45 minutes relaying information between the Coast Guard and the stricken *Carmen* until the signal from the vessel disappeared due to changes in propagation. It was at that time that a W5 in New Mexico acquired the *Carmen*'s signal and continued the relay between the Miami Coast Guard and the *Carmen*.

As a result of Mike's quick thinking, the Coast Guard dispatched a rescue plane which dropped a pump, rescue raft, and marine Coast Guard radio. Later, the cutter *Sherman* took the stricken 75' *Carmen* in tow and brought it back to Montego Bay, Jamaica. A spokesman for the Coast Guard credited the success of the rescue to Mike's quick thinking and positive action. Because he maintained his cool, three men who might have drowned are alive today. They have a 13-year-old amateur radio operator in Torrance, California, to thank for this.

THE "HAIL-TO-THE-QUEEN" DEPARTMENT

Nate Brightman K6OSC is another amateur we can all take pride in. He is a ham who had a dream and persevered for twelve years to see it come true. Thanks to Nate, amateur radio is now operational in full view of the general public on a day-to-day basis aboard one of southern California's most renowned tourist attractions: the *Queen Mary* ocean liner now permanently docked in Long Beach harbor.

Nate is a member of the Associated Radio Amateurs of Long Beach, California. Twelve years ago, when the *Queen Mary* made her last sea voyage from England to her final home in Long Beach, Nate and his club thought that it would be fitting to have an operational amateur station on the trip. Nate spearheaded the drive and succeeded. It was at that time that the idea of a permanent station came to him. Having an idea and making it come true are not always one and the same. In this case it took years. During its transition from an ocean liner to a tourist attraction and hotel, the original wireless room had been dismantled. Nate's idea was to restore this room to as close to its original state as possible and then add a permanent amateur station.

On April 22, 1979, Nate's dream came true. On that evening, Sharon and I attended a special invitational press preview of what had been accomplished by Nate and the Associated Radio Amateurs of Long Beach. On the top deck of the illustrious *Queen*, the wireless room had indeed been restored. Amid the relics of times gone by was nestled neatly, in a special panel arrangement, some of today's most sophisticated amateur equipment on indefinite loan from such well-known firms as Yaesu, Trio-Kenwood, Swan, DenTron, and others. What about antennas? Neatly built into one of the *Queen's* stacks and rising above it stands a triband beam and a two-meter Ringo from Cushcraft. The array is rotated by an Alliance rotor. Shortly, two dipoles (one for 75/80 and another for 40 meters) will give the ship's station 80- through 2-meter capability (six meters excluded).

Something very apropos happened the evening that the station opened. After the initial ceremony was concluded, it was time to place the station on the air. One of those present was famed DXer Don Wallace W6AM. When his turn came, Don contacted a station in New Zealand. As the QSO progressed, it was learned that the ZL had been one of the wireless operators who served on the *Queen Mary* during World War II. I remember the ZL saying, "Don, if you are where I think you are, then I preceded you some 30 years ago and had my feet in the same spot that yours are now." All of us gathered around the TS-820's speaker beamed with delight. If the QSO had been planned—and it was not—nothing could have been

A very happy Nate Brightman K6OSC (center) chats with Roy Neal K6DUE (left) and WA6ITF during a break in the filming of "The World of Amateur Radio" aboard the Queen Mary. *(Photo by KH6IAF)*

OMNI HAS IT *ALL*. All the advantages and capabilities, all the new conveniences and new levels of performance you need, whatever your HF operating specialty. All built-in, ready to use.

***ALL* SOLID-STATE.** All the advantages of total solid-state from the pioneer of HF solid-state technology. Reliable, cool, stable — from receiver front-end to transmitter final.

***ALL* HF BANDS.** From 160 through 10 meters (and all the crystals) plus convertible 10 MHz and "AUX" band positions for possible future needs.

***ALL* BROADBAND.** Band changing without tuneup — without danger to the final amp.

***ALL* READOUTS.** Choose OMNI-A for analog dial (1 kHz markings) or OMNI-D for six 0.43" LED digits (100 Hz readability.)

***ALL* VOX AND PTT FACILITIES** built-in; 3 VOX controls plus PTT control at front and rear jacks for external PTT switch.

***ALL* SQUELCH NEEDS** for tuning and monitoring are built-in.

***ALL* FILTERS INCLUDED:** 4-position CW/SSB filter (150 Hz bandwidth with 3 selectable skirt contours) plus 8-pole Crystal filter (2.4 kHz bandwidth, 1.8 shape factor.)

***ALL* MODE SWITCH** puts all filters to work in any mode.

***ALL* BREAK-IN:** Instant or delayed receiver muting to fit any band condition or mobile operation.

***ALL*-VERSATILE OFFSET TUNING;** dual ranges, ±5 kHz range for off-frequency DX or ±0.5 kHz range for fine tuning.

***ALL*-SENSITIVE RECEIVER;** from 2 μV on 160 m to 0.3 μV on 10 m (10 dB S+N/N) for ideal balance between dynamic range and sensitivity.

***ALL* OVERLOADS HANDLED;** dynamic range typically exceeds 90 dB and PIN diode switched 18 dB attenuator also included for extra overload protection.

***ALL* LINEAR/ANTENNA BANDSWITCHING FROM FRONT PANEL;** auxiliary bandswitch terminals on back panel for external relays or circuits are controlled simultaneously by the OMNI bandswitch.

***ALL* INTERFACE JACKS FOR PHONE PATCH;** access to speaker and microphone signals.

***ALL*-LEVEL ADJUSTABLE ALC;** set output from low power to full, retain low distortion at desired drive to power amp.

***ALL* SIDETONE ADJUSTMENTS;** pitch and volume.

***ALL*-POWERFUL, *ALL*-WARRANTED FINAL AMPLIFIER.** 200 watts input to final. Proven design with full warranty for first year and pro-rata warranty for additional 5 years.

***ALL* 100% DUTY CYCLE.** For RTTY, SSTV or sustained hard usage.

***ALL*-MODE POWER:** basic 12 VDC for easy mobile use, external supplies for 117/220 VAC operation.

***ALL* FRONT PANEL MICROPHONE AND PHONE JACKS.** Convenient.

PLUS *ALL* THE OTHER HANDY BUILT-INS: "Timed" 25 kHz crystal calibrator in OMNI-A with automatic 5-10 sec. "on" time for easy 2-hand dial skirt adjustment . . . Zero-Beat switch for placing your signal exactly on CW listening frequencies . . . SWR bridge switches "S" meter to read SWR each time you transmit for continuous antenna monitoring . . . Separate receive antenna capability . . . Dual speakers for greater sound at lower distortion . . . Plug-in circuit boards for fast, easy field service.

***ALL*-FUNCTIONAL STYLING.** "Clamshell" aluminum case clad in textured black vinyl with complementary nonreflective warm dark metal front panel and extruded aluminum bezel and bail. Convenient controls. Complete shielding. And easier-to-use size: 5¾"h x 14¼"w x 14"d.

AND *ALL* THE OPTIONS: Model 645 Keyer, Model 243 Remote VFO, Model 248 Noise Blanker, Model 252MO AC Power Supply.

Model 545 OMNI-A $899   Model 546 OMNI-D $1069

Experience the *all*-encompassing HF world of OMNI. See your TEN-TEC dealer or write for *all* the details.

OSCAR Orbits

Courtesy of AMSAT

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Oh, heavy sigh and deja vu, didn't we have a computer program in last July's RTTY Loop? Of course we did, but, as promised last month, this is the other half: the transmitting program for the 6800. Let's plunge right into the program, shown in Program 1. If you have the flowcharts from last month handy, use them along side.

The first 96 memory locations ($20 to $7F) are reserved for the table used to convert ASCII to Baudot. The ASCII value is used as an index to retrieve the data, representing the Baudot representation of that ASCII code. The encoding used represents the Baudot case as the Most Significant Bit (MSB), "1" for Letters and "0" for Figures, and the next five bits the character itself. Thus, ASCII "R", which has a value of $52, is found at memory location $72 [$20 (start of table) + $52 (R value) = $72]. The data at that location is $A8, which, in binary, is 10101000. This interprets to 1 - 01010 - 00, or LTRS - Baudot code 01010 (R). The last two bits are not used in this scheme. Note that, for example, a "4", which is ASCII $34 and found at location $54 in the table, would be represented by $28. This is binary 0 - 01010 - 00. That is, FIGS - Baudot code 01010 (R), since "4" is the uppercase Baudot "R".

COLOMBIAN INDEPENDENCE DAY CONTEST
Starts: 0001 GMT Saturday, July 14
Ends: 2359 GMT Sunday, July 15

The purpose of this contest is to commemorate the Colombian 169th independence anniversary and to promote and increase DX activity of HK radio amateurs. Entry classifications include: single operator/single band, single operator/multiband, multi-operator/multiband/one rig. Use all amateur bands 80 through 10 meters on phone, SSB, or CW. Only one contact per band with the same station will be permitted. No crossband or crossmode contacts. Club stations can only take part as multi-operator/multiband/single transmitter. A minimum of 50 QSOs must be shown in logs when applying for any award.

EXCHANGE:

RS(T) and QSO number from 001.

SCORING:

Each QSO with an HK station scores 5 points, each station in another continent counts 3 points, a station in a DX country counts 2 points, and stations in the same country count 1 point. The multiplier is the total number of different countries worked on each band. The total score will be the sum of QSO points on each band multiplied by the sum of different countries worked on each band.

ENTRIES AND AWARDS:

Logs must show all times in GMT; keep separate logs for each band and enter the country only the first time it is contacted. Each entry must be accompanied by a summary sheet listing all scoring info. The logs not summarized according to the abovementioned instructions will be used only as check logs. Awards include a silver plate for the world winner, certificates for continental winners, and winners in each classification. Violation of the regulations of amateur radio in the country of the contestant or the rules of the contest, taking credit for incorrect QSOs or multipliers, or duplicate contacts in excess of 2% of the total made will be deemed sufficient cause for disqualification. The LCRA Contest Awards Committee decisions shall be final. All logs must be mailed to: LCRA—Concurso Independencia, c/o Contest Committee Manager, Apartado Postal 584, Bogota, Colombia, SA. All entries must be postmarked no later than September 30.

CW COUNTY HUNTERS CONTEST
Starts: 0000 GMT July 28
Ends: 0200 GMT July 30

The CW County Hunters Net invites all amateurs to participate in the 1979 contest. All mobile and portable operation in less active counties is welcome and encouraged. General call is "CQ CH." Stations may be worked once on each band and again if the station has changed counties. Portable or mobile stations changing counties during the contest may repeat contacts for QSO points. Stations on county lines give and receive only one number per QSO, but each county is valid for a multiplier. Suggested frequencies are 3575, 7055, 21070, and 28070. It is requested that only portable or mobile category stations call CQ or QRZ on 40 meters below 7055 and on 20 meters below 14070 with all stations spreading out above those frequencies.

EXCHANGE:

QSO number, category (portable = P, mobile = M), RST, state/province/country, and US county.

SCORING:

QSOs with fixed stations are 1 point; portable or mobile stations are 3 points. Multiply the number of QSO points times the number of US counties worked. Mobiles and portables calculate their score on the basis of total contacts within a state.

AWARDS:

Certificates will be awarded in three categories: Fixed—highest fixed or fixed portable station in each state, province, and country with 1,000 or more points; Portable—highest station in each state operating portable from a county which is not his normal point of operation with 1,000 or more points; Mobile—highest mobile in each state operating from 3 or more counties with a minimum of 10 QSOs per county.

Trophies will be awarded to the highest single-operator station in the US in categories P and M. The awards committee will issue additional awards where deemed appropriate.

ENTRIES:

Logs must show category, date/time in GMT, station worked, exchanges, band, QSO points, location, and claimed score. All entries with 100 or more QSOs must include a checksheet of counties worked or be disqualified from receiving awards. Enclose a large SASE if results are desired. Logs must be postmarked by September 1 and sent to: CW County Hunters Net, c/o Jeffrey P. Bechner W9MSE, 673 Bruce Street, Fond du Lac Wi 54935.

RHODE ISLAND QSO PARTY
Contest Periods: 1700 GMT Saturday, July 28 to 0500 GMT Sunday, July 29
1300 GMT Sunday, July 29 to 0100 GMT Monday, July 30

This contest is sponsored by the East Bay Amateur Wireless Association. RI stations work other RI stations and the rest of the world. Others work RI only. The same station may be worked once per band and mode. No repeater contacts are allowed.

EXCHANGE:

RS(T), QTH = RI county or state, province, or country for others.

SCORING:

RI stations score 2 points per QSO; RI Novice and Tech stations score 5 points per QSO. Others score 2 points per RI QSO and 5 points per QSO with RI Novices or Technicians. RI Novices and Technicians sign with /N or /T to designate license class. RI stations multiply total QSO points by the number of RI counties, states, provinces, and DX countries worked. Others multiply total QSO points by the number of RI counties worked (5 max.). All stations score 10 points for QSO with multi-op station operated by club members, N1RI.

FREQUENCIES:

CW—1810, 3550, 3710, 7050, 14050, 21050, 21110, 28050, 28110.

SAMPLE-AND-HOLD DEVICES

Sample-and-hold (S/H) devices or sample-and-hold amplifiers (SHA) are analog circuit elements that are the analog equivalent of the digital latch. They are used when we wish to sample an analog signal and then hold it steady at a particular point so that a voltage of interest may be measured or used elsewhere in a system. The operation of an ideal sample-and-hold device is shown in Fig. 1. In this example, the S/H output follows, or *tracks*, the input during the sample period and then holds the latest analog voltage when it switches to the hold mode. In the figure, the input and output voltage lines are offset slightly for clarity.

Sample-and-hold devices are widely used in conjunction with digital-to-analog and analog-to-digital converters. For example, they may be used to:

- Hold an analog signal steady so that an A/D conversion may be performed;
- Simultaneously sample many analog inputs for later measurement (requires one S/H device per analog input);
- Deglitch a D/A converter's output to eliminate output voltage spikes or settling transients; and
- Distribute one D/A converter's output to several points, where analog voltages must be constantly maintained.

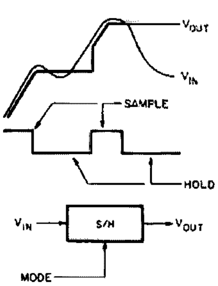

Fig. 1. Inputs and output for an ideal sample-and-hold device. Both the sample and hold modes of operation are shown.

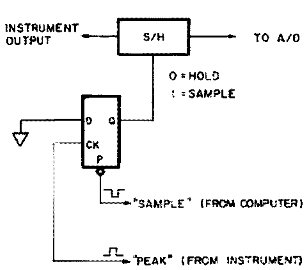

Fig. 2. Block diagram for a typical sample-and-hold microcomputer interface circuit. The instrument supplies the PEAK input pulse to the flip-flop. The SAMPLE pulse from the computer presets the flip-flop to logic 1.

The second and fourth uses listed above are becoming less important than they were two or three years ago. It is probably less expensive now to dedicate an A/D converter to each input to be measured and to have one D/A converter per output, depending upon the specific application.

The most common use of sample-and-hold devices is to sample and hold an analog signal at a particular point while it is measured with an A/D converter. A sample-and-hold device is particularly useful in situations in which a DAC and a comparator are being used in conjunction with microcomputer software to create an A/D converter.[1] When a sample-and-hold device is used prior to the input of the unknown signal to the comparator (or an A/D converter module if one is used), the digitization may proceed to give an accurate representation of the unknown voltage. For example, in Fig. 2 we provide a block diagram for a typical sample-and-hold computer interface that permits you to measure the peak voltage from an instrument. We have assumed here that the instrument provides a positive clock pulse, called PEAK, when the peak maximum is reached. The SAMPLE pulse from the computer allows the S/H module to sample the unknown signal from the instrument. When the peak is reached, the PEAK signal clocks a logic 0 into the output of the flip-flop, forcing the S/H device into the hold mode. Fig. 3 shows the timing diagram that would be generated by the interface circuit shown in Fig. 2. Again, the S/H output and the instrument output have been offset for clarity. Now, either a slow ramp A/D converter or a fast successive approximation A/D converter can be used to provide the correct value for the peak voltage since the S/H device will maintain the voltage until it can be digitized.

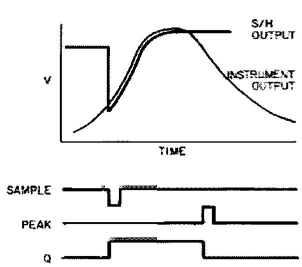

Fig. 3. Typical timing diagram for the interface circuit shown in Fig. 2.

acquisition time	The time required to go from the hold state to the tracking state, in which the output remains within a 0.01% range of the input. This may also be called the settling time when the S/H device is already in the sample mode. The acquisition time is generally a few microseconds. See Fig. 4.
aperture time	The time period required by the device to go from the sample mode into the hold mode once the hold command has been received. The aperture time is generally a few nanoseconds. See Fig. 5.
droop rate, decay rate	The rate of discharge of the sample-and-hold capacitor. The rate is a function of switch leakage current and the current required by other circuit elements connected to the capacitor. It is expressed as millivolts per second. See Fig. 6.
gain error, linearity	The variation of the observed output from the expected output over the entire sample-and-hold device's output voltage range. It is usually expressed as a percentage, say 0.01%. See Fig. 6.
offset	The difference between the input and the output voltages of the device when the input is ground. It is usually expressed as millivolts. The offset may be adjusted to zero using external components, but it will generally change with time and temperature. See Fig. 4.
slew rate	The maximum rate of change for the output, expressed as volts per second. It is a limitation imposed by the charging rate of the capacitors and the actual slew rates of the operational amplifiers present in the S/H circuit. See Fig. 4.

Table 1. Some important concepts associated with sample-and-hold devices.

Sample-and-hold devices are not ideal, and there are some terms that will help you better understand their limitations and uses. These are listed in Table 1, which is keyed to Figs. 4, 5, and 6. As can be observed, there are important limitations to the capabilities of S/H devices. Those devices that have short acquisition times use small capacitors and thus the voltage droop rate will be large. The use of larger capacitors means that the acquisition time will be longer, but the voltage droop will be less. When high acquisition speeds and long hold times are required in an application, two S/H modules may be used: The first quickly acquires the analog signal at the point of interest and the second acquires and holds the output from the first device. The second S/H device takes longer to acquire the voltage presented by the first device, but since a larger capacitor is used, its droop rate will be much lower. For further details, the reader is referred to reference 2.

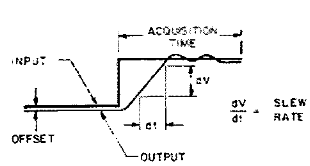

Fig. 4. Representation of the acquisition time, offset, and slew rate. (Courtesy of Analog Devices, Inc.[3] All rights reserved.)

There are a number of commercially available sample-and-hold devices which eliminate the need for you to construct your own. The following modules are representative of those available:

Analog Devices, Inc., Norwood, Massachusetts 02062—SHA-5, general purpose, $47; SHA-1A, general purpose, $150.

Burr-Brown, Tucson, Arizona 85734—SHC80KP, low cost, $34; SHM60, high speed, $104.

Datel, Inc., Canton, Massachusetts 02021—SHM-LM2,

New Products

KANTRONICS' AMATEUR UPGRADE™

Kantronics' "Amateur Upgrade" is an educational board game that familiarizes players with FCC rules governing amateur radio and elementary radio concepts. The game comes complete with playing surface, playing pieces (coil, grommet, etc.), a die, a deck of exam cards, and corresponding answer sheets.

"Amateur Upgrade" is packaged in a colorful light blue box; it measures 1.5" high by 8.25" wide by 15.5" long. Game pieces and exam cards fit in a pocket adjacent to the support tray. The game surface is 15.4 inches square and is printed in five colors corresponding to beginner, Novice, General, Advanced, and Extra class.

Players roll the die to determine the number of spaces to move. Some spaces players land on have a consequence, such as "taught a Novice class—move again," or "exceeded 1000 Watts—answer question; if wrong, go to start," or "illegal third party traffic—lose one turn."

When a player lands on an exam space, he must take an exam card from the card pile corresponding to the license level he is trying to upgrade to. After three cards have been collected by one player, he must "take the exam." All three questions must be answered correctly to pass the exam. Answers can be checked against the answer sheets. If the exam is passed, the player moves up (upgrades) to the adjacent exam space on the next license level. If the exam is failed, the player remains on the same level and must collect another three exam cards.

The first person to progress through all levels to obtain the Extra-class license wins!

Novice, General, Advanced, and Extra-class questions are included. For a less advanced game, the Novice cards can be used exclusively for all license levels.

Kantronics, Inc., 1202 E. 23rd St., Lawrence KS 66044; phone (913)-842-7745. Reader Service number K13.

NEW COMMUNICATIONS RECEIVER FROM NATIONAL RADIO

National Radio now offers the latest version of its Model HRO-600 high precision/performance solid-state general-coverage communications receiver, conceived for applications requiring wide frequency coverage, high stability, sensitivity, and selectivity. The frequency stability of this professional receiver, over the temperature range of 0° to 50° C., will drift less than one part in one million, and, under normal operating conditions, it can be expected to drift less than one part in one hundred million. The receiver's fine-tune mode, using the Model 602 plug-in module, permits tuning to a fraction of 1 Hz without any loss of stability.

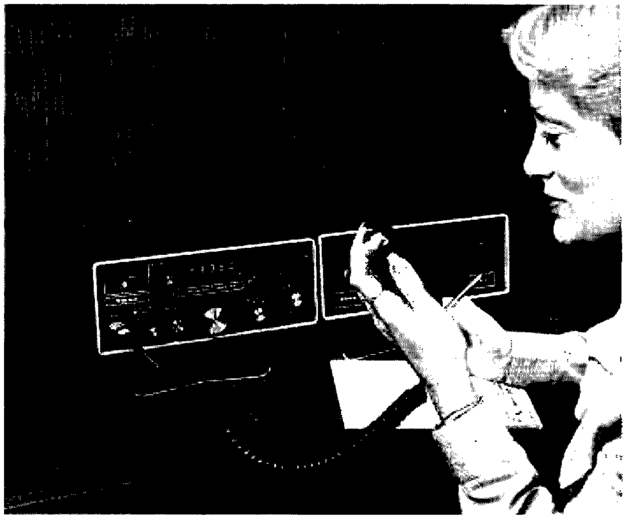
The HRO-600 was originally designed and built to the exacting requirements of the International Maritime Standards. With its versatile plug-in modules and accessories, the Model HRO-600 becomes a custom receiver designed to meet users' specific needs at the lowest cost. The manufacturer states, "The HRO-600 is unmatched in performance and versatility in its price range."

The receiver's excellent rf selectivity from 16 kHz to 30 MHz is achieved by a built-in tunable preselector. Depending upon the plug-in module selected, the receiver will operate at any frequency between 10 kHz and 30 MHz in any of the following reception modes: AM, CW, SSB, FSK, and FAX.

The basic applications of the HRO-600 include: commercial communication, ship-to-ship, ship-to-shore, ground-to-air, frequency/time measuring, process control, laboratory instrumentation, military, paramilitary, international monitoring, limnology, etc.

The HRO-600 meets applicable military standards as to shock and vibration, has an operating temperature range from 20° to +55° C., measures 5¼" high x 17" wide x 15½" deep, and is provisioned for self-supporting rack mounting. The approximate weight is 40 lbs., available from stock, FOB factory.

For additional information, write or call Robert Reeves, Sales Manager, *National Radio Company, Inc., 89 Washington St., Melrose MA 02176; phone (617)-662-7700.* Reader Service number N23.



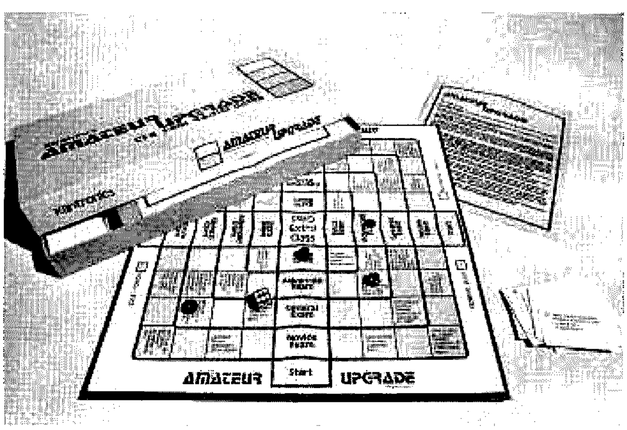
The Astro 150 from Swan.

SWAN'S ASTRO 150 TRANSCEIVER

Swan Electronics Corporation has announced its newest entry into the amateur radio market with the introduction of the Astro 150 transceiver, featuring microprocessor control and memory.

The new solid-sate transceiver, with its microprocessor control, provides more than 100,000 digital-controlled frequencies and variable rate scanning (VRS). VRS is a dramatic new method of tuning which provides ease and accuracy and works in conjunction with hand-held microphone scanning. With microphone "up" and "down" pushbuttons, the Astro 150 can be tuned in accurate 100-Hz steps or at a fixed rate scan. VRS is a supplement to the Astro 150's conventional tuning knobs.

The compact new radio also has additional features which include 235 Watts input power, full and semi break-in CW, narrowband CW filter, expanded frequency coverage, and microprocessor-controlled frequency memory.



"Amateur Upgrade" game from Kantronics.

National Radio's latest version of the HRO-600.

The Astro 150 will be sold through Swan's worldwide network of dealers. For further information, contact Gary Pierce at *Swan Electronics Corporation, 305 Airport Road, Oceanside CA 92054; phone (714)-757-7525.* Reader Service number S44.

METZ COMMUNICATION'S AMATEUR ANTENNAS

Metz Communication Corporation has broad experience in producing mobile-type antennas. However, until recently, the company has concentrated its sales efforts in the commercial land mobile and marine radio markets. Now Metz has entered the amateur marketplace with mobile antennas for the 10-meter, 2-meter, and 70-cm bands. I installed and operated the 2-meter version, the Mobile 2, in preparation for this review.

The commercial heritage of the Metz amateur antennas is readily apparent. Instead of the usual plastic tube to protect the base loading coil from the weather, the Metz coil is housed inside a machined stainless steel cylinder. This cylinder, in turn, is filled with epoxy to completely encapsulate the coil . . . no more worries about a leaky base coil.

The tapered stainless steel whip is held in place by a metal ferrule that is (would you believe?) gold-plated to prevent corrosion. Overall, the construction of the Metz Mobile 2 is so rugged that it will probably still be going strong when you and I are long gone.

The Mobile 2 is designed to operate as a half-wavelength antenna on the 2-meter band. This design makes the antenna a bit shorter than the more familiar 5/8-wavelength 2-meter antennas. I consider the reduced length a plus; in my case, it made the difference between being able to mount the antenna on the car roof (the best location) and being relegated to the trunk lip (for fear of bashing the whip against the garage door).

In operation, the Mobile 2 is a breeze. When cut for lowest swr in the center of the 2-meter band, it's possible to operate from 144-148 MHz with an swr of 2.5:1 or better. Of course, if you work primarily in one end of the band or another, you can optimize the performance for that portion of the spectrum.

I found the Metz to be equal to or better than my 5/8-wave antenna in every respect. Additionally, the completely weatherproof design of the Mobile 2 means that leaking and condensation around the coil are never going to be a problem; you get full performance even in the worst weather. The Mobile 2 is rated at 200 Watts for those who need the extra punch of a linear amplifier. Several mounting styles are available in addition to the excellent magnetic mount I used.

For those who demand quality construction in everything they own, the Metz antennas are going to be tough to beat. *Metz Communication Corporation, Corner Routes 11 and 11C, Laconia NH 03246.* Reader Service number M100.

A NEW CONSUMMATE DIGITAL VOLKSMETER

Non-Linear Systems' new Model LM-353 3½-digit digital Volksmeter was designed to include numerous advanced state-of-the-art features. The LM-353 is packaged in a small 1.9-inch-high by 2.7-inch-wide by 4-inch-deep attractive plastic case. It weighs only 9.2 ounces.

Basic functions include ac and dc volts, Ohms, and ac and dc milliamperes. Full-scale ranges are 1, 10, 100, and 1000 volts, 1, 10, 100, 1000, and 10,000 kilohms, and 1, 10, 100, and 1000 milliamperes.

In addition, a low-Ohms capability is present which provides for in-circuit test of resistive components. It is particularly useful for in-circuit test of resistors shunted by semiconductor devices because the low compliance voltage provided does not turn on the semiconductor.

The low-Ohms function adds other capabilities to the meter. It can be used to increase the sensitivity of the voltage ranges by a factor of 10. It provides a 0.1-kilohm resistance range having 100 milliohm resolution. In addition, the milliamperes function is enhanced in two ways. First, a .1-milliampere range is available. Second, the voltage drop across the internal current shunt is reduced by a factor of 10. Measurements from 100 nanoamperes to 100 milliamperes can be made in this mode.

The LM-353 utilizes an LCD display. Replaceable AAA-size batteries allow up to 100 hours of operation. Standard features include auto polarity, decimal location, input overload protection, and automatic zeroing.

Options include a tilt-stand case for bench use and a panel-mount flange case for installation into equipment. A 45-kV high-voltage probe and leather carrying case are also available.

The complete NLS digital Volksmeter line is sold through a worldwide network of leading electronic distributors. The Model LM-353 will be available from distributors in July. *Non-Linear Systems, Inc., PO Box N, Del Mar CA 92014; phone (714)-755-1134.* Reader Service number N22.

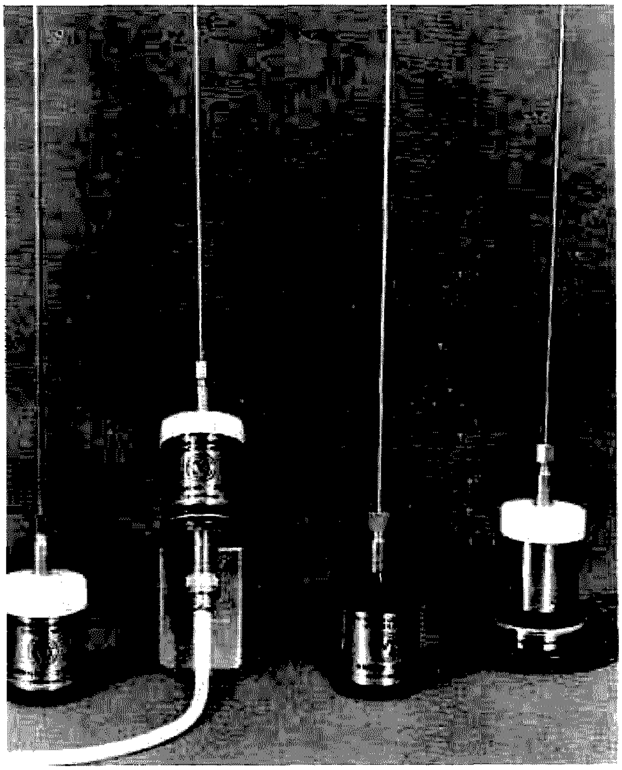
NEW 300-WATT DRY RF LOAD RESISTOR

The new Bird model 8173 TERMALINE® dry high-power coaxial load is designed for 50-Ohm rf-line and system termination during design, test, and alignment. At 300 Watts continuous duty, it complements the present Bird Dry Loads group ranging from 2 Watts through 600 Watts. The group, with its rugged construction and air dielectric (no liquid coolants), now includes 2-, 5-, and 10-Watt loads with fixed input connectors, and 25-, 50-, 100-, 150-, 300-, and 500/600-Watt loads with Quick-Change connectors.

The use of Bird QC Quick-Change connectors offers unsurpassed flexibility; a choice of any common rf connector either at the time of order or in the field eliminates adapters and degradation of performance.

Available from *Bird Electronic Corporation, 30303 Au-*



Amateur mobile antennas from Metz.

CDE INTRODUCES TWO NEW ANTENNA ROTOR SYTEMS

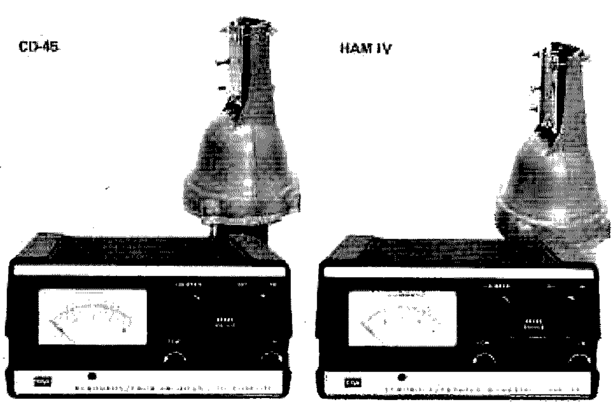
Two new models of high-performance antenna rotor systems, the Ham IV™ and the CD-45, have been introduced by Corneil-Dubilier Electric Corporation, Newark NJ.

The new Ham IV is designed for large communication antenna arrays up to 15.0 sq. ft. wind load area when tower-mounted. Highlights of the Ham IV include power braking, machined steel drive gears, dual transformer circuitry, and other design features that make it "the engineered choice" for serious communicators.

The new CD-45 accommodates antenna arrays up to 8.5 sq. ft. wind load area when mounted in a tower and features a professionally-styled control unit, illuminated metered readout, all-steel drive components, automatic disk braking, and more.

Both the Ham IV and the CD-45 operate at safe low-voltage control levels with reliable snap-action rotational controls for accurate, trouble-free operation.

For more information, write Leonard Sabal, *Cornell-Dubilier Electric Corporation, subsidiary of Federal Pacific Electric Corporation, 150 Avenue L, Newark NJ 07101; phone (201)-589-7500.* Reader Service number C143.



New antenna rotor systems from CDE.

ANTECK MT-1 MOBILE ANTENNA

Improved conditions on the HF DX bands has stirred increased interest in mobile operation on those frequencies by many amateurs. In mobile operation, the antenna is even more important than it is in fixed installations. For one thing, if you've got an inefficient antenna at home, you can always help to make up for its shortcomings by running more power. However, while there are a handful of mobile kilowatts around, most amateurs have to be satisfied with the output from their transceiver, usually in the 100-Watt range.

So, for effective mobile operation, an efficient antenna is of prime importance. It should also be easy to install and tune, weatherproof, and allow band changes without having to change coils. The new Anteck MT-1 certainly meets those requirements and, when properly installed and tuned, should provide a high degree of performance on the HF bands.

The frequency coverage of the MT-1 is 3.5 to 30 MHz, making it perfect for use on MARS and other non-amateur frequencies (in addition to the 10 through 80-meter amateur bands). Its power handling capability is 750 Watts PEP. The MT-1 consists of three main assemblies: mast or base section, loading coil, and whip. The overall length of the mast section and loading coil is 60 inches and the diameter is approximately 1 inch. The total antenna length is 116 inches at 3.5 MHz and 92½ inches at 30 MHz. The antenna is center-loaded on all frequencies except 29 to 30 MHz, where it works as a quarter-wave vertical.

Properly mounted and tuned, the MT-1 will display the vswr/bandwidth shown in Table 1.

The loading coil is tuned from the base of the antenna, using a non-inductive plastic rod which is attached to the base of the whip assembly and extends down into the bottom mast section. The antenna comes with a handy chart that correlates the numbers on the antenna's tuning scale to frequency. To set the antenna for a particular frequency, loosen the knurled nut in the slot in the base section four turns and push the tuning rod to the middle of the base tube so that the tuning rod will move freely without binding. Then set the top of the nylon collar to the position called for on the tuning chart for the frequency in use and retighten the knurled nut. That's all there is to tuning the Anteck MT-1.

The MT-1 mobile antenna is manufactured entirely in the United States using only the best-quality military-standard materials and components. Its three-piece modular construction (base section, loading coil, whip assembly) makes for ease of repair or replacement if damaged. There is a 90-day warranty. Factory service is available.

The net price for the MT-1 mobile antenna is $119.95. *Anteck, Inc., 239 Cedar Street, Box 543, Jerome ID 83338; (208)-324-3400.* Reader Service number A80.

MICRONTA 12-VDC 8-AMP POWER SUPPLY

Now available from Radio Shack is a new power supply that converts standard 120 V ac house current to 12 V dc at up to 8 Amps output for powering high-power auto sound equipment, mobile CB transceivers, and amateur radio equipment at home.

The Micronta 12-volt 8-Amp power supply includes a heavy-duty transformer and 35-Amp bridge rectifier for handling high current demand devices. Filtered output reduces "hum," and ripple is less than 2 volts peak-to-peak with a full 8-Amp load, according to Radio Shack.

A built-in manually resettable circuit breaker protects the supply and your equipment from damage. An LED indicates power on.

Manufactured in Radio Shack's own USA factory, the power supply is housed in a metal cabinet with rubber feet. Size—3-3/4" x 8" x 5-5/8".

The Micronta 12-volt 8-Amp power supply is available exclusively from participating

NOVICE CORNER

This month we want to pass along a little QSL advice that is aimed not only at the newcomer but to a lot of the oldtimers as well.

If you work a station, such as a DXpedition, several times on different modes at different times, please do not place a card for each contact in an envelope addressed to the QSL manager and include only one SASE.

Because there are often several logbooks involved and several different people or groups handling the QSLing chores, you will stand a much better chance of getting a fast return if you include a separate SASE for each QSL card. If the extra expense is too much to bear, then you really don't need the extra cards.

While we are on QSLing, we will remind you again to always use GMT/UTC time on your card including the date, be sure that your call appears plainly on the report side of your QSL, and to always include a self-addressed, stamped envelope when sending a card to a QSL manager. When sending a card overseas, either direct or to a foreign QSL manager, include a self-addressed envelope along with a dollar bill, foreign mint stamps, or sufficient IRCs to prepay the return postage.

CARIBE DX ASSOCIATION'S PLANS

The Caribe DX Association's Alex Kasevich W1CDC is presently in the process of engineering a large DXpedition to some rare place on the globe. All interested persons who feel they meet the requirements listed should apply for an interview. The time window for this adventure is August, 1980; exact dates will be made available when government legalities and logistics permit.

They have a large seaplane with a pilot and a co-pilot at their disposal. A large manufacturer of amateur equipment has endorsed their intentions by the loan of some top-of-the-line ham gear.

All persons who apply must hold a current amateur radio license, General class or higher; they must also have a doctor's endorsement indicating that they have no physical restrictions that could be affected by extreme heat, sun, humidity, sea/air sickness, possible physical exhaustion, and insect bites. All members shall be proficient CW/SSB contest-style operators and must have a secondary ability to contribute to the expedition in the following categories: 2 persons with some paramedic training; 1 doctor; 2 cooks; 1 navigator; 1 antenna specialist; 1 electronics (solid-state) technician; 1 mechanic, gasoline generator maintenance.

All members of the expedition must be able to swim and have some climbing ability.

These requirements have been made not to discourage anyone from taking part, but to ensure the safety of all members and make the DXpedition a success. It must also be clearly understood with all members that there is always the possibility of hidden dangers in pulling off a trip of this magnitude. I'm sure all of you will have various questions about this subject, and they will be answered in the best interest of all parties concerned.

Please send your reply with your remarks, phone number, and best time to contact you to: The Caribe DX Association, c/o Alex M. Kasevich W1CDC, PO Box 93, East Glastonbury CT 06025.

HEARD ON THE BAND

That 4W2AA being heard from time to time appears to be I2YO who travels to Yemen on a regular although infrequent basis. QSL to I2MVS.

GJ2LU is the official QSL manager for any Isle of Jersey stations.

PY1RO is the first DX station ever to make WAS on 160 meters.

A recent article in the Russian *Radio* magazine notes a decision by the USSR State Commission on Radio Frequencies to allow amateur activity between 1850 kHz and 1950 kHz. Although no date was given, it seems definite that you should be hearing the Russians on 160 meters any day.

Anyone wanting to learn more about the action on 160 meters should drop a note to W1BB along with an SASE and request a copy of Stu's very informative bulletin.

The African swing by N6VR and WA6VNR netted some 3000 contacts from C5ABX/C5ABZ and 2200 from /6W8. They had a 5T5 permit, but time and funds ran out before they got to Mauritania. QSL to 48 South Chestnut Street, Ventura CA 93001.

Slim has been pulling overtime lately what with the good band conditions and cheap airline rates. If you worked any of the following, then know that you have met Slim himself: 6B1B, J1A, 7O1AA, 9N1AB, BY1USA, CR9CB, XZ2BC, KL8AA, and, of course, VR0M from Maiden Island. Being the bashful sort, Slim generally prefers CW, but on occasion he can be found on the phone bands. If you hear the generator whine, you know it's Slim.

SV9JI on Crete has a weekly schedule with W2TDQ on Tuesdays at 2100Z on 14288 kHz.

Lloyd and Iris Colvin, of YASME DX fame, report that with the end of their recent West Indies swing, they have held 104 different callsigns, visited 135 countries, and have made over 500,000 QSOs. They have a QSL file of over 250,000 alphabetized cards, probably the largest collection in the world. *Guinness Book of World Records* is missing out.

A station has been worked on fifteen signing HV2VO and giving his name as Brother Edmund. Said to QSL via I0GPY. This could be the Vatican Observatory station we mentioned a few months back.

Those EJ prefixes heard over the May 18/20 weekend were special calls issued for operation by several GI stations from Inishmurray Island. QSL to GI4FUM.

VR6HI was number 100 on 160 meters for PY1RO.

VP8SU from South Georgia can usually be found with WA2JUQ in a list-type operation every Tuesday/Wednesday/Friday on 14240 kHz around 0100Z. QSL to G3RCA.

After much waiting, the necessary documentation was forwarded to ARRL Headquarters and they are now accepting HZ1BS/8Z4 cards for DXCC credit.

For some time now, rumors have been thick concerning an upcoming Franz Joseph Land effort by some of the UA/UK types. Along this line, UA1OE advised W4ORT that there would be something coming this July. UK1ZAA advised KH6GI that UK1PAA was the only station on FJL and it was crystal controlled on 14030 kHz. Listen for Franz Joseph Land to be activated . . . someday . . . maybe.

9N1BMK was true blue. QSL to his home call JA8BMK.

YU2DX returned home from the Sudan where he was doing some educational work in the electronic field. A radio club has been organized in Khartoum and the club call is 6T1YP. Both 6T1YP and 6U1DX can be QSLed to YU2DX. Other new calls being heard out of the Sudan lately are ST2FF and ST2MM.

U0CR was Leo UA3CR, part of a seven-man skiing team headed for the North Pole. U0CR counts for the RAEM award.

That linear shipped to Father Dave CE0AE should be in use now and the signal should be much improved. CE0AE can often be found on the various DX nets such as the Family Hour on 14225 kHz at 1500Z or the Afrikaner Net, 21358 kHz from 1830Z. Overseas commercial interference has forced the Afrikaner Net to move up from its normal 21355-kHz spot.

4U1UN has moved its location to the 48th floor of the Secretariat at UN Headquarters in NYC. They still have only dipoles and a vertical, but they are working on permission to install a beam.

3B8DA has been inactive most of this year trying to clean up the backlog of some 20,000 cards received as the result of some of his recent operations.

The VR6HI operation from Pitcairn Island by ZL1AMO and ZL1ADI produced an almost unbelievable QSO total of better than 33,000 contacts spread out over six bands. The fewest contacts came on 160 meters with 170, and the most, 10,885, were made on 10 meters. During this same period, VR6BJ and VR6DX from the *Yankee Trader* made 753 and 1100 QSOs respectively. 193 of VR6BJ's contacts were on RTTY. These three operations should have dropped VR6 well down on the needed list.

New officers for the Mile-Hi DX Club are Roger Preece WB0RTZ—President, Bob Pierce WB0OGJ—VP, and Joe Hart WB0HAD—Secretary/Treasurer.

SV1JG expects to be on Rhodes in the Dodecanese group this summer signing SV1JG/SV5. Under the new call allocation scheme there in Greece, SV5 is Dodencanese and SV9 is Crete. This was done no doubt to aid the deserving DXer in his never-ending search for a new one.

Several VE types are working on the necessary permission to activate Sable Island during July or August. They have authorization from the DOC but were awaiting other required documents before firming up the details.

As this column is being written, the YV0AA DXpedition is going hot and heavy giving out a new one to deserving DXers all over the world. While we realize the DX bands are crowded these days, it seems a little ridiculous to spread the calling stations out over a forty kHz section of the band. Listening from 14200 kHz to 14240 kHz makes that section of the band useless for any normal DX activity and certainly does little to

enhance our image among the sizable segment of our fellow amateurs who somehow fail to see the need to bring the normal day-to-day activities of amateur radio such as skeds, ents, SSTV, etc., to a screeching halt while we deserving ones strive to exchange signal reports with a temporary station located on an uninhabited island covered solid with birds and their natural residue. How anyone could fail to understand this and start complaining about *those DXers* is certainly beyond us. Transmitting below the American phone band and listening up is the only way for many DX stations to be able to make any contacts with USA stations, but it seems that listening over, at most, a fifteen or twenty kHz portion of the band should be sufficient. How do you feel about this practice?

Still nothing heard from China but a few phonies. A usually reliable source from Europe reports that one of the eastern Eurpean countries will be sending a team of radio technicians to help the Chinese develop knowledge in that area. Some among this team will be amateurs ready to demonstrate the finer points of amateur radio should the opportunity arise. The source seems rather definite that something will be heard this fall.

There are serious discussions going on between some of the biggest of the big-gun-type DXers concerning a concentrated effort this summer to wipe Mt. Athos (SY) from the face of the most needed lists. More information will come as plans gel.

If you think some exciting times can't be experienced in amateur radio, then you obviously were not in on the recent 1S1DX operation from Spratly. The initial landing was planned for Amboyna Cay. When the Spratly crew got close, they could see that there were people on the island and they cautiously came inside the reef to a point some 300 yards offshore. Through binoculars it was easy to detect military personnel in black uniforms grouped around what appeared to be weapons. One of the military types began signaling with semaphore signals, but unfortunately no one in the crew understood the signals. As the crew moved in closer, the message became somewhat clearer as four warning shots were fired across their bow. Feeling at this point they were not wanted and seeing that they could easily be blown out of the water with little effort, the little group again headed out to sea.

After this initial problem, the group returned to Brunei, regrouped, and decided to make another run, but this time to Pearson Reef, located some eighty miles northeast of Amboyna Cay and hopefully less inhabited since it had an elevation of only three feet above high tide. The approach to Pearson Reef showed how when it rains, it pours. Not only was the small reef occupied, but there were buildings and small craft around. Fortunately, the group had selected a third alternate, which they now headed for. It was from this spot, Barque Canada Reef, a sand bar some 150 feet in length, that the much-delayed, constantly-in-danger 1S1DX operation finally took place.

Most of the sixty hours stay on Barque Canada Reef was spent operating, often with more than one station on the air. Ten, fifteen, and twenty netted some 13,300 contacts with about half coming on fifteen. Phone seemed to result in a higher QSO/hour rate, so the concentration on this mode resulted in a 77%/23% phone/CW split. Forty percent of the contacts were with Japan, thirty-five percent were with stateside, fifteen percent were with Europe, and the remainder were scattered around the world.

QSL to Harry Mead, Box 85, Round Corners, 2158 Australia. Expenses were excessive due to the problems and any financial aid can go to K2TJ or via the Northern California DX Foundation.

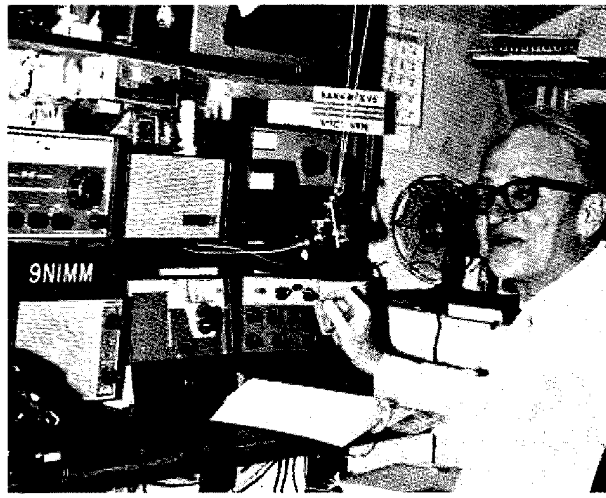
The recent volcanic activity on St. Vincent Island in the West Indies found VP2SQ providing emergency communications for the local authorities. He is reported as having phone-patched Prime Minister Cato to other islands when there was a need for quick communications. It is this type use of amateur radio that we have been trying to demonstrate to the Third-World nations preceding WARC 79.

Rubin WA6AHF and his XYL Ferne have had to curtail their YASME QSLing efforts on the recommendation of their doctor. Although giving up the YASME effort, they will continue to handle cards for those stations they are QSL managers for.

Some EP stations are again being heard on a sometime basis, although the situation is far from being settled in Iran.

That 9N1YU being worked a few months back is reported by HS1ABD to be a true-blue type used by a Yugoslav mountaineering group in the Mt. Everest area.

S2BTF continues to show from Bangladesh on the weekends working a list-type operation. Look for him on 14226 kHz Saturdays from 1300Z and Sundays from 1200Z. QSL Peter via Box 108 in Dacca.



Father Marshall D. Moran, S.J., Kathmandu, Nepal, better known around the world as 9N1MM. Father Moran has been a regular fixture on the DX bands since 1961.

9N1MM has been keeping a fairly regular schedule around 14243 kHz after 0100Z. QSL to Ed Blaszczyk N7EB, 12802 Sun Valley Drive, Sun City AZ 85351. Ed has been handling Father Moran's QSL duties since 9N1MM first came on the air in 1961. Ed, who has also held the calls W3KVQ, W2KV, and KX6EB, asks that we remind those needing a 9N1MM QSL to please enclose an SASE. It makes the job much easier.

As we have often mentioned, it's usually easier and cheaper to just enclose a dollar bill (green stamp) with your QSL when a direct airmail reply is required than to go through the hassle of buying IRCs or foreign mint stamps. We also mentioned that there were situations when it was best not to enclose money with a QSL going overseas. A letter from Mansur AP2MQ brings up a case in point. Incoming mail is often checked by the Pakistani postal authorities, and since the importation of foreign currency is illegal in Pakistan, this often leads to embarrassing circumstances for the amateur to whom such mail is addressed. It is always best to follow the QSL instructions given by the DX station. In the future, do not send green stamps to Pakistan.

There is a report that the number of complaints to the FCC concerning the Russian "woodpecker" have risen sharply. It is sometimes a bit frustrating to report such interference and realize that the person on the other end has never heard of the "woodpecker." Check last month's column for the telephone number of your closest FCC monitoring station. Keep them advised of the "woodpecker's" activity and someday the "woodpecker" will vanish. Some claim that if we had reacted immediately two years ago, he would now be only a bad memory.

A couple of months back we mentioned the possibility of a Swedish group operating from Albania. The expected callsign was mentioned as being ZA5T. Late word on this operation has been zilch, but if anything new develops, we will certainly pass it along.

Those new Pacific area prefixes still seem to be causing trouble. It was sure easier to remember when KM6 was Midway, KW6 was Wake, etc. To help you learn the new designations, we will list them again:

KH1	Baker, Canton, and Howland
KH2	Guam
KH3	Johnston
KH4	Midway
KH5	Kingman if K suffix, Palmyra if not
KH6	Hawaii
KH7	Kure
KH8	American Samoa
KH9	Wake
KH0	Northern Marianas

UK0YAH is being worked around 14050 kHz after 1800Z. We mention this as a reminder that Soviet Siberian stations whose suffix begins with a Y are located in Tana Tuva in rare Zone 23.

The Brussels Millennium Award is available to anyone working ten of the OS prefixes on at least two bands. Send log data and three IRCs to Brussels Millennium Award, PB 1000, B-1040, Brussels, Belgium.

Continued on page 172

A Visit to Antenna Specialists

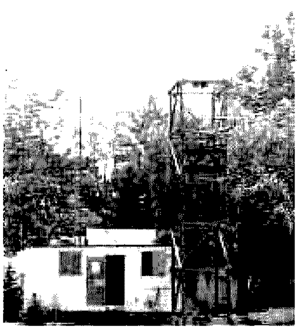
—Wayne tours the test range

Wayne Green W2NSD/1
Editor/Publisher

The science of measuring antenna performance as part of the design process has come a long way in the last twenty years. A recent visit to the Antenna Specialists test site in northeastern Ohio brought back memories of my past visits to other such sites . . . and the enormous changes in test equipment and procedures which have come about.

Let me tell you about my visit to Antenna Specialists' test site.

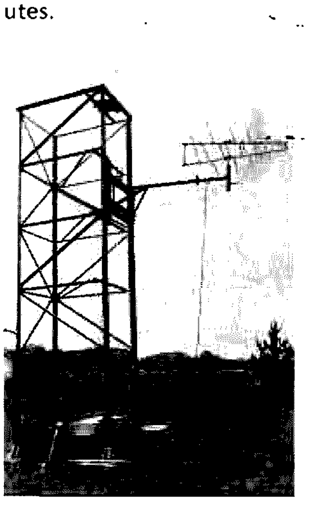
Sherry and I were met at the Cleveland airport by Al Dolgosh K8EUR, who led us out to the test site, over an hour's drive away. There we met Dick Leach WA3HSE/WB8ZAA, Tom Baker K8MMM, and Rick Davis K8DOC, the test site team. The lab was set up in a trailer with a reference dipole nearby. The test antennas were set up on a platform a couple hundred feet away.



This is the trailer with the laboratory equipment for running the antenna field strength tests. The tower to the left is for a ham station in the house to the rear of the trailer. It's nice to have a ham living right there to watch out for the test lab equipment.

Was it only a little over twenty years ago that I visited a top manufacturer of ham antennas and watched them run tests on a long two-meter beam, measuring the signal strength every few degrees and writing down the figures? Today, this is all automatic. Today, they can run tests in a few minutes that used to take days, thus making it possible to design much more effective antennas. When you can make a small change in the antenna design and measure the results of that change quickly, it is relatively simple to explore many more variables for optimum performance.

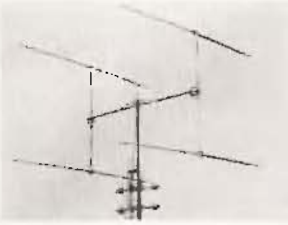
With modern equipment at a test site, it is possible to measure the vertical and horizontal radiation characteristics of an antenna as well as the frequency response—all in a few minutes.



This is a small tower right beside the mobile lab. It is designed for mounting the transmitting antenna for the tests. Notice that this antenna can be raised and lowered to get the optimum vertical pattern of radiation.

You're looking at an enormous investment in test equipment. This gear is made just for labs of this nature and allows the automatic testing of the antennas, complete with the graphing system on the right.

Here Tom is showing the reference antenna which he set up by the receiving platform. This is a simple reference dipole.



The tests this day were going to be run on the Antenna Specialists 44-element beam.

This is the mechanism which is used to hold up the antenna to be tested and to turn it in time with the graph in the lab. The tilting gears allow the antenna to be brought down for mounting or changes. The whole mechanism is on the track and can be moved toward or away from the lab.

That's Tom on the left in back, Al on the right in back, Rick on the left in front, and Dick on the right in front.

The test platform is being rotated so that the other two 11-element yagi antennas can be mounted on the boom. The rotating is all done remotely from the trailer.

Al Dolgosh K8EUR, who organized everything for us.

Rick Davis K8DOC, who is lucky enough to live at this extremely low-noise test site, complete with his ham rig and a good beam.

Tom Baker K8MMM.

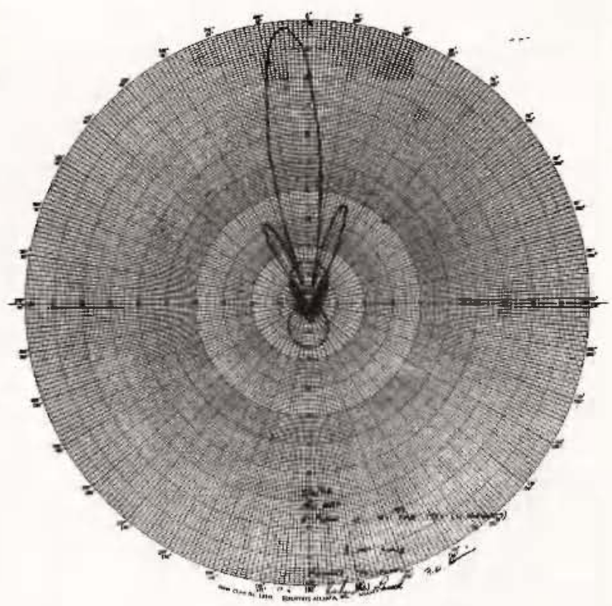
Dick, Al, and Tom get the beam onto the boom and tightened in place for the tests.

Here's the beam all set up and raring to go, about 300 feet from the source site.

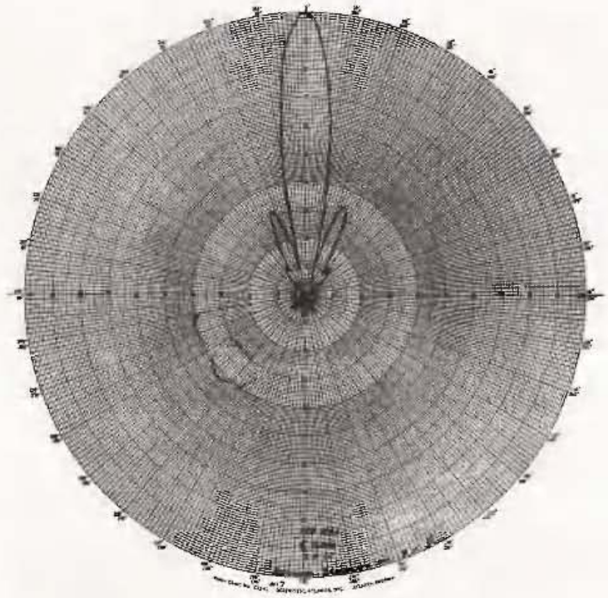
Dick runs the antenna array through a complete rotation, watching the pen on the chart as it traces the pattern of the beam.

Here you see the finished pattern of the array. How about all that gain! And you surely can null out the interference with that incredible front-to-back ratio.

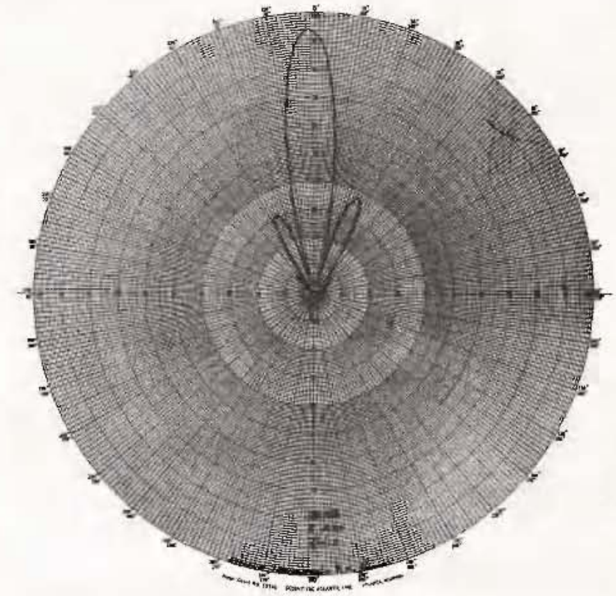
Over to the right of the test platform I found these tracks. They are for rotating cars to measure the radiation patterns of mobile antennas mounted on different parts of different cars. They drive the



This is the pattern drawn by the chart recorder for the 44-element array on 146 MHz with the comparison from a reference dipole (dotted line).



This is the same array, but measured at 148 MHz. Not a lot of difference—certainly none that you would ever notice in use.



One more run was made with the array on 144 MHz to make sure that it was capable of working over the entire 2m band. It takes a lot of careful design to make a high-gain array such as this work over a four-megahertz bandwidth with as little loss as this one shows.

car with the test antenna onto the tracks and then rotate the whole works to get the pattern. It's quite a complete test site facility.

After the test, Al had the 44-element array boxed up and shipped to the 73 lab. It took longer than we figured to get it airborne, due to some serious delays in getting a promised tower. The antenna puts out one whale of a signal, as you can see from the pattern on the graph. ■

Reader Service—see page 211

Secrets of Guyed Towers

—put 'em up and keep 'em there

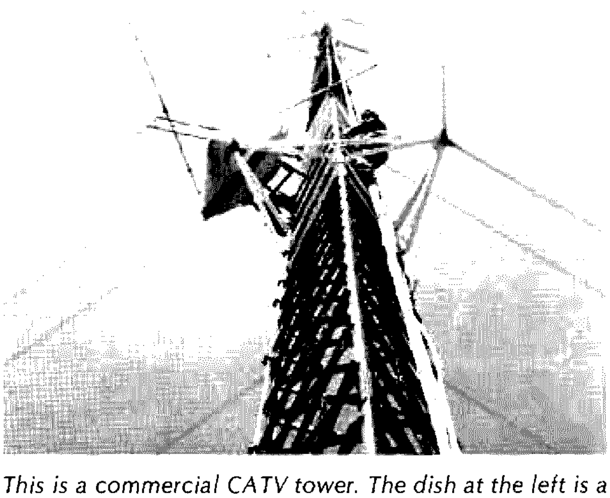
Trade real estate for security.

Peter Carr WB3BQO
329 Little Avenue
Ridgway PA 15853

There is an old saying among hams that "if it stays up, it's too small." Who among us can truthfully say that on those long winter days we haven't spent a moment or two thinking how great it would be to have a five-element, 40-meter beam in the backyard, fed with 2 kW, and a hundred feet above ground? Dreams? Well, maybe. But it's sure that whatever your idea of the "ultimate" antenna array, it's got to be held up by something.

Since the best antenna farm starts with the support equipment, let's look at the best antenna support: the guyed tower. A tower is like a chain, in that it is only as strong as the weakest link. Self-supporting towers are linked to Mother Earth at one point—the base. Guyed towers, on the other hand, have four support points over which to spread the load—three anchors and the tower base. The penalty for this added strength is the larger chunk of real estate required to accommodate the guy-anchor supports.

In planning to erect a tower, there are some decisions and compromises to be made. One must be realistic about what will adorn the top of the tower and the worst case of wind loading that can be anticipated. The antenna load must be added to the wind loading to determine the total load environment in which the tower will be operating. Most antenna manufacturers publish load figures as part of their advertising, or will furnish data on request. The same goes for tower makers, and they also have data about



This is a commercial CATV tower. The dish at the left is a microwave receiving antenna. Mounted below it is a "star mount" anti-torque guy wire/frame system. The tower height is 500 feet.

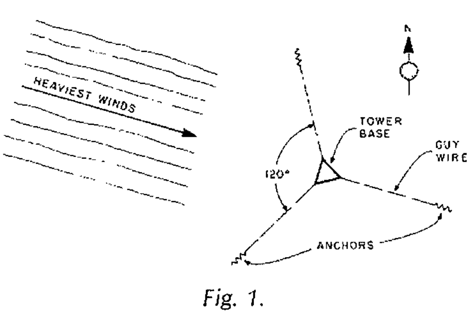


Fig. 1.

Here is a commercial tower anchor and "eyeplate." Note the length of guy wire laced through the turnbuckles to prevent loosening.

The bottom two guys shown here are attached to the anchor plate and to the "star mount" just below the microwave dish.

wind and ice conditions throughout the country to help in figuring the operating load.

As a rule of thumb, anchors should be placed out from the tower base a distance of between one-half and two-thirds the tower height. For a hundred-foot tower, this means the distance from base to each anchor will be from fifty to seventy-five feet. Since this distance determines the angle of the guys at the tower, it represents a compromise between the ideal one-foot-up for one-foot-out, or guy angle of forty five degrees, and some even sharper guy angle which conserves real estate. These considerations outline the practical limits of tower height.

Other factors which limit tower height are: surrounding objects like houses and trees, sloping terrain, local building codes, and neighbors. Each should be taken into careful consideration since towers are no less expensive to take down than to put up.

Since the load of a tower is in two parts, it is best to look at each in choosing a brand and model of tower. The side load is the force which is supported by the anchors and guy lines. The vertical load is supported by the tower and base alone. Most towers are triangularly shaped, and the wider the spread between the vertical legs and the larger in diameter they are, the greater the vertical load they will hold. Knowing the antenna loading figures and the weather conditions for your area, it is possible to have a tower manufacturer recommend the proper size tower for your needs.

Two last considerations should be figured into the choice of heights. How far will the rig be from the antenna, and what will the cable loss be, compared to the benefit of added height? In addition, who will service the array? It seems that the number of volunteer climbers varies inversely with the height of the work!

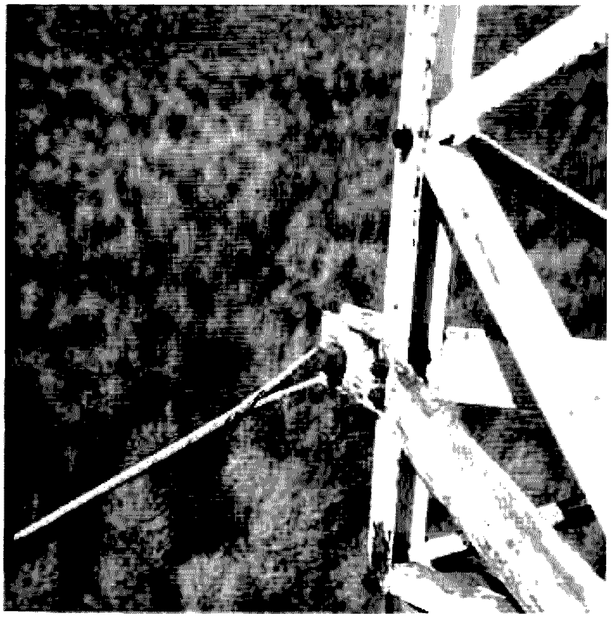
Planning the actual construction is the next step in the process. Survey the land for the locations of the base and anchors. Let's say you come up with a layout similar to the one in Fig. 1.

In this "helicopter" view of the project, we see that the anchors are laid out 120 degrees apart and that two of them are upwind of the tower base. This spreads the worst of the wind loading between two anchors.

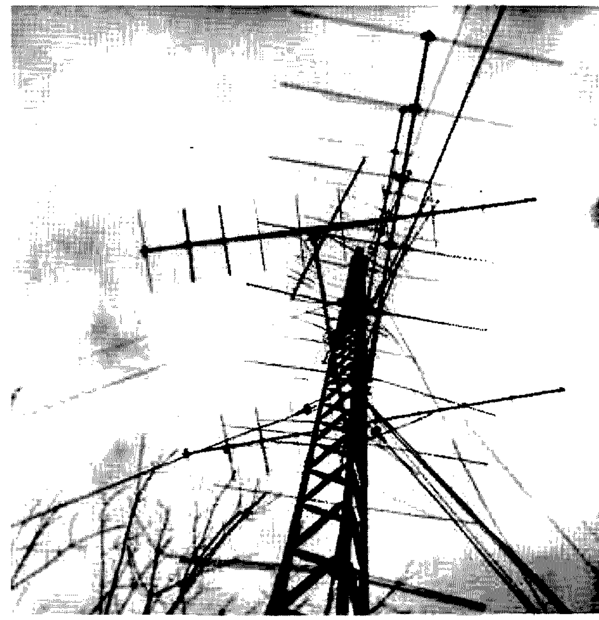
The type of soil will determine what type of anchor should be used. There are screw-type units which don't need a hole but are screwed into the undisturbed earth. These are okay for smaller systems with light loading and with firm to slightly-rocky soil. The other type is the bell anchor which requires that a hole be dug. The bell-shaped bottom of this type of anchor is attached to a long rod which sticks out of the ground after the anchor is placed in the hole. When the bell is struck with a heavy bar, the anchor will spread out and dig into the sides of the hole. The hole is then backfilled using small rocks and well-tamped dirt. These bell anchors hold a larger load since they are bigger at the bottom and deeper in the ground than the screw type.

The tower base also is chosen after considering the type of soil at the construction site. Since the base has to support only the vertical load, it doesn't have to be very deep. It should be down far enough, however, so that frost will not cause it to shift position. Manufacturers' recommendations should be followed here so that a firm footing is assured.

Finally, make a list of the required tools and gear for the actual job. Try to obtain the services of someone who has done similar work before, and rely on his experience. If no hams are around to fill the bill, try the local power or telephone company. Their construction crews routinely handle projects similar to this, and probably will know where you can obtain the ropes, guy/jacks, strain dynomometers, and climbing equip-



Guy wires and preformed wrap-on grips are shown at the tower end. Note that the bolt acts as an axle for the grip. The height is 375 feet.



A Dill tower in CATV service is pictured here. The tower is 100 feet tall, in 10 foot sections weighing about 60 pounds each. The sections are 11 inches on a side.

ment you will need.

Before getting into the actual nuts and bolts of hanging up the tower, it's good to discuss various aspects of safety on the job. Advance planning on paper of each step in the process will allow each member of the crew to familiarize himself with the sequences involved. Line up enough people to do the job, and don't forget that at least one should be experienced. All climbing tools and small hand tools should be in first-class shape. Hardhats are a must for the ground crew, and no one should be closer than twenty feet to the tower base for any reason other than to attach gear to the ropes going up the tower. The auxiliary leg, which sometimes is used to hold the weight of a tower section as it is placed on already erected sections, should be inspected carefully. The combined weight of the leg and section can do considerable damage and injury if they fall.

The Dill tower base rests on a large flat rock two feet down and buried in small rocks and well-tamped dirt.

When everything needed is on hand, the anchors are dug in, and the necessary personnel have been lined up, it is time to pick a day to complete the job. Weather is the main consideration here since to be safe the entire job should be completed in one day. The Flight Service Center at the local airport is an excellent source of weather information, and their forecasts of wind conditions are especially good.

On the morning of the big day, begin by bolting the first three sections of tower together on the ground. Attach to the top of the assembly three guy wires which have been cut to roughly the correct length. Set the bottom of the assembly next to the tower base (which is in the ground) and lay out the guy wires down the length of the three-section assembly, over the base, and straight out beyond. With one man holding down on the bottom to make it dig into the ground, and three more pulling at the guy wires, have the remaining people lift the top of the tower and raise it over their heads. As they walk toward the base raising the tower above them, the guy wire attendants will steady the tower side-to-side while at the same time helping to pull the tower vertical.

When this move is completed, the tower should be standing on the ground next to the base, stabilized by the guy wires. Next, lift the tower onto the base and install the three bottom bolts. Attach the guy wires to their respective anchors, and, using a spirit level, a plumb bob, or other sighting line, snug up the guys until the tower is exactly vertical. This operation is important since when later sections are installed, the tower will be put into a bind if it is not

The anchor rod holds three guys using preformed grips. The rod is six feet long and is buried nearly five feet down.

This is a partly installed preformed grip. No tools are needed, and it may be removed for re-tensioning of the guys and easily reapplied.

exactly vertical.

The climbing people are now sent aloft, and the auxiliary leg (or stiff-leg), pulleys, and hand ropes are made ready to raise the next tower section. Since it is very hard for a person to get good lifting leverage while leaning back in a line belt, the ground crew should raise each section while the climbing crew steadies it and guides its placement atop the last section erected.

Remember that during this operation those on the ground should not stand near the tower base, or in an area where dropped tools or parts might fall.

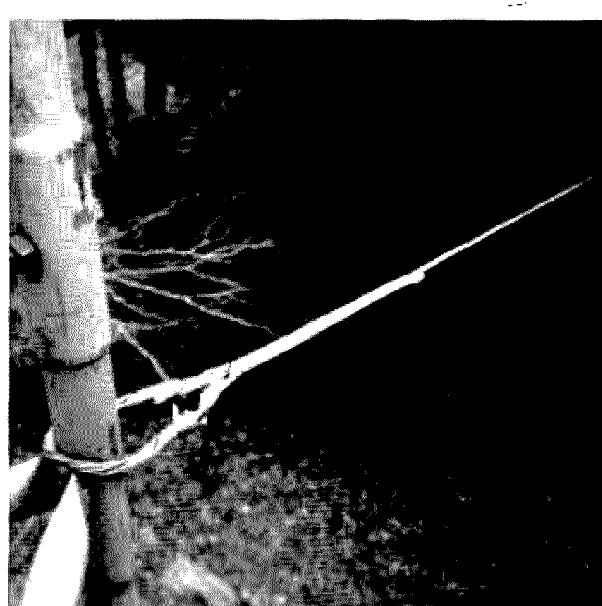
Continue adding tower sections and guy wire sets until the tower is complete. Since the last section normally is built to accept an antenna rotator and mast, these items are more easily installed before that section is raised.

Having aligned the tower each time that a set of wires was installed, the complete unit should be pretty close to vertical. By sighting upward along each leg of the tower, any bends will be seen easily and can be removed by adjusting tension on the appropriate guy wire.

Now that the tower is straight, the next step is to equalize the tension on each set of guy wires. A device called a strain dynomometer is used to read tension on a cable. If this is not available, the only recourse is to pull each guy wire slightly out of line and feel the tension by hand. Sighting up each guy wire from anchor toward the tower and judging the sag is another method, but it is not as reliable due to the varying lengths of the lines. The aim is that each guy wire should carry the same strain as every other.

The tower is now complete and ready to accept antennas and downleads. Even though it is ground-mounted and is attached to guy wires and anchors which also are at earth ground potential, it still is wise to electrically ground the tower. Most commercial installations use a six-foot ground rod at each tower leg, driven as close to the base as possible. This is sufficient to protect the tower, although lightning protection at the shack end of the downleads still should be used. In the event that lights are required, or any source of commercial power is used at the tower, the ground system should be tied into the neutral of the electric line.

When very large arrays are rotated on a tower, the torque will cause twisting of the structure. While this does not affect the life of the tower, it does affect the aiming accuracy of VHF directional arrays during windy conditions. The cure is to install another guy system by bolting to the tower a length of pipe or angle iron about six feet long, as per Fig. 2.



Guy wires and grip are attached to a tower leg.

Since this guy system carries only the twisting load applied to the tower, it need not be as heavily constructed as the main system. Screw-type anchors and number ten steel fence wire are more than adequate, along with TV-type U-bolts connecting the pipe to the tower legs. With this arrangement mounted about three-fourths of the way up the tower, it should remove most of the twisting action and considerably reduce the whiplash effect on the antenna elements.

There you have it. Guyed towers offer the most stable platform for large arrays and greater heights under the most extreme weather conditions. They also offer confidence in the knowledge that those expensive antennas are mounted up where they operate best and are supported by a system which will offer safe and reliable operating for years to come. ■

Death-Defying PL Mod for the KDK 2015

—not for the squeamish

No more clipping.

Author's Note: Since this article was written, KDK has improved their "fix" by adding additional RC filters between the NOR gate and the base of the output transistor.

This article is not for the timid soul. It takes considerable courage to take a brand new rig and cut the circuit foil and drill holes in the PC boards. This statement is not intended to scare you off, but to forewarn you. The results, however, are well worth the effort.

A prerequisite for outlining any solution is to first define the problem. The basic complaint with the original KDK PL is that it may or may not activate a given repeater, and when it does, there are complaints of the PL being audible and clipping with modulation.

Investigation of the existing PL circuit reveals a CMOS 2-input NOR gate chip (MC14001) connected as a square-wave oscillator as shown in Fig. 1. They couldn't have planned it worse. The fast rise and fall time of the square wave produces many harmonics of the 100-Hz fundamental at 200, 300, etc., accounting for the audible complaint.

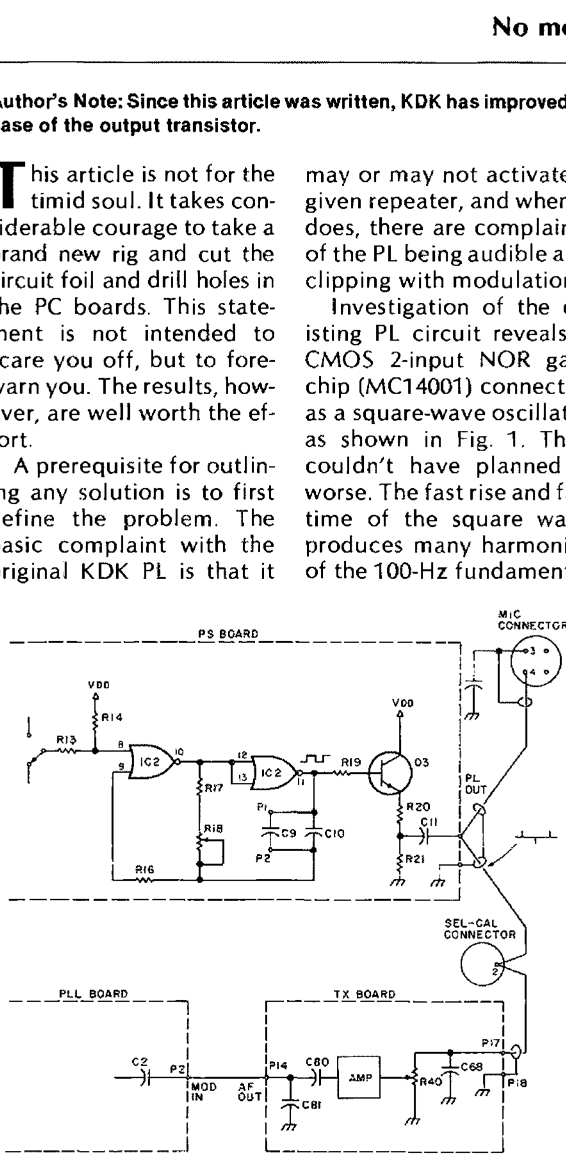

Fig. 1. Existing KDK PL circuit.

To make matters worse, the square wave is differentiated by the .01-uF coupling capacitor to the speech amplifier, producing narrow pulses from each edge of the square wave (pulse modulation, yet). This has to be a terrible shock to the preamp and is probably the reason why the repeater does not recognize the PL. Attempts to activate the repeater by increasing the PL level further aggravate the audible problem.

The official "fix" available as a modification kit from the US distributor of the KDK units leaves much to be desired, since it simply adds a 0.1-uF shunt capacitor from the base of Q3 to ground to drastically slow up the rise and fall times, making it a triangular wave.

The ultimate solution, of course, is to change the PL signal to a sine wave. This is where the timid souls can leave to purchase their ME-3. The hardy and courageous individuals, however, should stay while we discuss how to linearize the existing CMOS digital gate for analog operation to generate a sine wave.

Any digital logic-inverting element (NAND or NOR gate or inverter) produces a high-level output with a low-level input and vice versa. The input switching threshold for a CMOS logic element is approximately 45% of the supply voltage (9 volts in the KDK). When the input signal passes through the threshold (4 volts), the output switches. It is at this switching level that the gate is operating in the linear region. A feedback resistor connected from output back to input, as shown in Fig. 2, linearizes the gate since a high output fed back to the input would tend to drive the output low, which when fed back to the input tends to drive the output high, which . . . etc. The gate finally compromises itself with both input and output floating at the 4-volt switching threshold level.

This circuit configuration lends itself very well for a Wein bridge sinewave oscillator (sometimes

called a twin-T) by simply dividing the feedback resistor into two parts and adding the other necessary RC constants as shown in Fig. 3. The basic frequency of oscillation is given as $F = 1/(2\pi RC)$, but this is not exact and may vary considerably. A word of caution here: The capacitors must be a good quality ceramic or mica with good temperature stability, and the resistors must be 100 part-per-million temperature-coefficient units. One such circuit constructed with miniature plastic capacitors changed frequency by 50% when sprayed with Quick Freeze circuit cooler.

The final circuit design and KDK modifications are shown in Fig. 4. Note that the second gate is no longer used. The IC pad of pin 11 on the circuit board is still utilized, however, so the legs of the chip (pins 11, 12, and 13) were cut and a jumper added to connect circuit board pad 10 to 11 to complete the path to the output transistor. The legend for the various circuit modifications appears below the schematic. The 0.15-uF capacitor across the 287-Ohm resistor and 1k pot was required to eliminate a secondary high-frequency oscillation. The value of this capacitor, although not critical, will have some effect on frequency.

The major problem encountered was getting the PS board out far enough to work on it. There are a few wires from the PS board which are routed under the PLL board. This problem is solved by removing the four PLL mounting screws and tilting the board forward towards the front panel. A piece of masking tape will hold this board in the upright position.

The second problem is caused by the choke mounted on the rear plate and the ground wire from the power input connector. These leads are very short and make it impossible to move the PS board. It may be possible to unsolder the choke leads; however, I chose to unmount the choke, leaving it attached to the board. This is accomplished by gently removing the rear identification plate by lifting with a small screwdriver (sticky back) to expose the choke-mounting screws. The ground wire can easily be unsoldered at the power input connector.

The transceiver is then positioned on its side and the PS board separated as far as possible from the chassis with all other wires still connected. Not an ideal work situation, but tolerable.

The following is a complete step-by-step procedure for making the modification. Refer to the PS board layout diagram on page 12 of the KDK manual to locate the various points referenced.

1. Unsolder the two shielded audio cables from the PS board, cut them to a length sufficient for splicing, and cover the splices with shrink tubing. This disconnects the PL output and completes the microphone cable routing to the SEL-CAL connector and speech amplifier.

2. Cut the legs of pins 11, 12, and 13 on IC2.

3. Solder a jumper across pads 10 and 11 on rear of board.

4. Cut circuit foil between P1 and junction of R19 and C10.

5. Cut circuit foil between P2 and R18 potentiometer.

6. Replace R16 470k resistor with a 16.9k resistor.

7. Replace R17 33k resistor with a 14.3k resistor.

8. Replace R18 50k pot with a 5k pot.

9. Replace C9 .033-uF capacitor with a .15-uF capacitor.

10. Replace C10 .068-uF capacitor with a .15-uF capacitor.

11. Replace C11 .01-uF capacitor with a .22-uF capacitor.

12. Replace the combination of R20 4.7k and R21 470-Ohm resistors with a single 5k miniature potentiometer (about the size of a transistor). Mount this pot with one end in the R21 ground pad, the other end in the R20 pad which connects to the emitter of Q3, and the rotor in either of the two pads at the junction of R20, R21, and C11.

13. Drill a hole through the ground plane at the edge of the PC board in line with R16 and next to the nicad battery. Mount the .33-uF capacitor from the junction of R18 pot and R16 resistor to the ground-plane hole.

14. Position the 1k pot next to the nicad battery such that the rotor and one end are over the ground plane and the other end is over the open area (no ground plane). Mark the points, drill the holes, and mount the pot. Make sure the speaker clears the pot when the bottom cover is mounted.

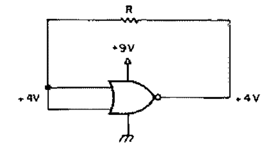

Fig. 2.

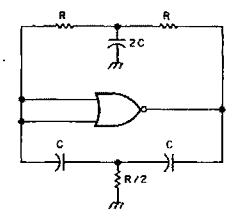

Fig. 3.

15. Drill two more holes in the open area for mounting the 287-Ohm resistor next to the 1k pot. Mount the resistor in the holes and bend one lead over and solder it to the open pot lead.

16. Drill another hole in the open area next to the 287-Ohm resistor hole and also another hole through the ground plane for mounting the .15-uF bypass capacitor across the 187-Ohm 1k pot combination.

17. Connect a wire from

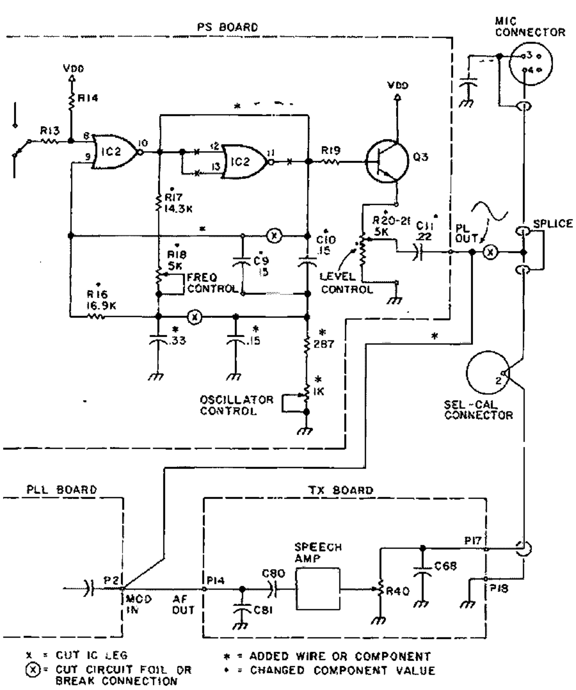

Fig. 4. Modified KDK PL circuit.

the junction of the .15-uF bypass and the 287-Ohm resistor to P2.

18. Connect a jumper wire from P1 to the pin 9 end of R16.

19. Connect a wire from "PL OUT" (open end of C11) to P2 "MOD IN" on the PLL board (terminal with green wire).

Adjustment is best accomplished with a scope and counter; however, it may be possible to "ballpark" the frequency adjustment by comparing it to a strong signal with PL on the repeater input with an auxiliary receiver. The 1k oscillation control should be adjusted for the maximum resistance possible that will sustain oscillation without distortion of the sine wave. A rough setting of the level control can be made by measuring the audio voltage level with a voltmeter at the "MOD IN" terminal under normal modulation and adjusting the PL "LEVEL" for 10% of this value. Final tweaking may require on-the-air tests with assistance from another operator.

This modification has been in use for several months with excellent results. Temperature stability is very good (±0.2 Hz) when sprayed with Quick Freeze circuit cooler (−50° F.) and heated with a heat gun. Both temperatures were well beyond my operating thresholds. Final results—no more clipping or complaints of audible PL with 100% solid QSOs.

Next project—slowing down the scanning rate so more than two words can be heard when continuously scanning the memory channels for familiar voices or calls. Maybe we can start a KDK "mod squad." ■

Feed-Horn Mounting Made Easy

—solution to a pesky problem

More on microwaves.

Dr. Ralph E. Taggart WB8DQT
602 S. Jefferson
Mason MI 48854

Until you know a little bit about the subject, the antenna portion of a microwave project seems quite simple. The most difficult aspect is building or finding a dish—or so it seems! No matter how you acquire the dish, however, you will discover that your problems have just begun.

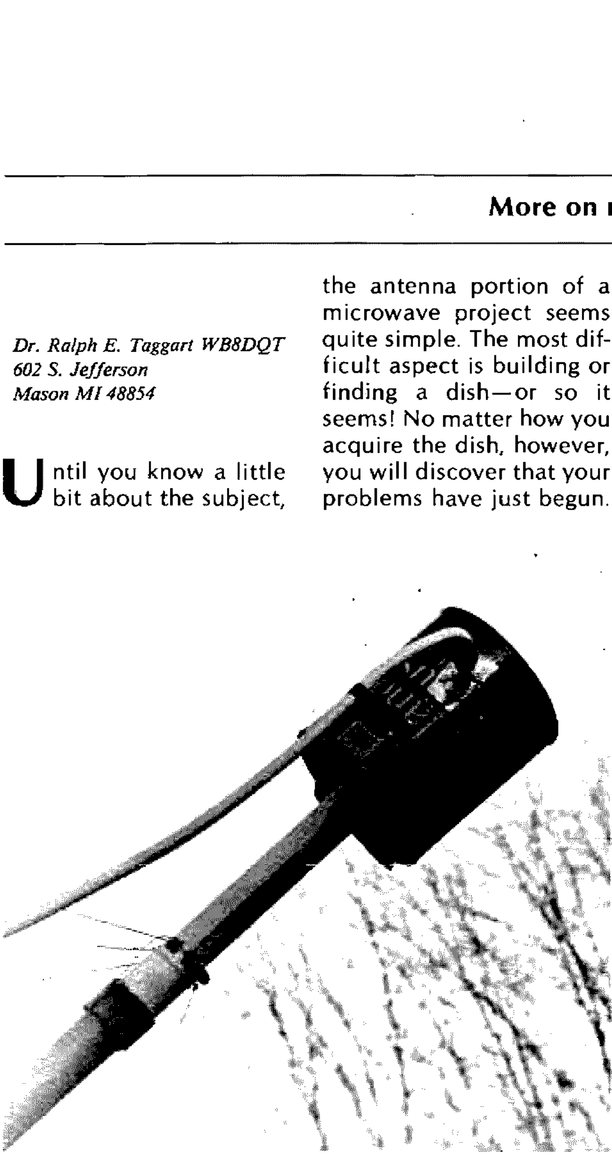

Photo A. This is a feed-horn assembly for use at the 1.7-GHz satellite frequency.

Next you must find a suitable feed, and if this search leads you into the literature, you will discover that that subject can be quite complex indeed.

In the final analysis, one of the simplest and most effective feeds in the low-frequency end of the microwave region is the horn feed. Rectangular horn feeds are superior, in the sense that the illumination pattern can be controlled with some precision. Their main drawback is that they are mechanically unwieldy.

Despite their reduced illumination efficiency, cylindrical feed horns are quite popular in that they can be constructed of metal pipe, tubing, or cans. A number of articles have appeared in the amateur literature describing the construction of horn-feed systems. They are quite non-critical in use—particularly in receiving applications.

Horn Mounting

Once you have obtained a dish and constructed a horn, you inevitably encounter the real problem—how to get the darn thing mounted! I have been working on antennas in the low microwave region (S-band) for the past two years now, in conjunction with a series of projects involving the GOES weather satellites. These satellites transmit pictures on a frequency of 1691 MHz, and thus I was forced to deal with the feed-horn mounting problem. The answer to it has proved to be quite simple and effective and should be applicable to similar situations involving operations on 1296, 2304, and 3300 MHz.

The key point in any mounting scheme is to avoid obscuring the open end of the horn with metal in any form. Any metal will serve to shield out a certain portion of the received rf, all of which will be focused into the mouth of the horn in a well-designed system. The two most common mounting schemes are shown in Fig. 1. One of

these is excellent but largely impractical, while the second is very inelegant and somewhat inefficient.

The first involves the use of either three or four spider-arm assemblies running from the horn to the periphery of the dish. The arms do not impede the rf front reflected from the dish surface into the horn, and they can be made even of metal for, although they do intercept the wave front as it arrives at the dish, their area is quite small compared to the area of a typical dish; the gain reduction is not measurable.

This does, however, highlight why obstructions to the horn are so critical. *All* the rf energy reflected by the dish surface must pass into the relatively small opening represented by the mouth of the horn. Any metal obstruction here can cancel out a good percentage of the gain!

The primary disadvantage of the spider-arm system is the difficulty in fabricating it. One must have considerable mechanical ingenuity to devise fastenings to secure the arms to the horn and to the edge of the dish. The arms must be of equal length, provide rigid support, and must hold the horn at the proper focal length for the dish in use while also permitting rotation of the horn to match polarization with the transmitted signal. Since the precise position of a particular feed horn relative to a particular dish at a given frequency can be determined only approximately at first, one is in for a considerable period of tinkering to get everything right.

The second approach is to use a support rod at the center of the dish—usually fabricated of plumbing tubing and fittings—with an offset to accommodate the horn radius, as shown in Fig. 1(b). The horn is clamped to the tubing using large hose clamps or some other system. It is an easy system to adjust, since the horn can be moved up or down the tube for focusing prior to being clamped in place. The major disadvantage is that the tube does absorb rf coming in from the dish surface. Also, the system looks terrible!

Figs. 2 and 3 show a much better system. The horn is mounted to a square of unclad G-10 board material (no copper) using four small metal brackets outside of the horn. The G-10 square is just slightly larger than the outside diameter of the horn, and the horn brackets attach within the corner areas that extend beyond the edge of the horn.

Other materials may be used for the mounting square if they pass a simple test. Simply hold a sheet of the material across the mouth of the horn and observe the indicated signal strength on the receiver. If there is no noticeable drop in the signal level, you are getting minimal attenuation and the material may be used. Most plastics appear to work fine, but be sure to check them out anyway, as the composition of a few plastics or their additives can sometimes show unexpected rf absorption at some frequencies in the microwave region.

The mounting square is attached to a mast of PVC plumbing tubing (don't use metal!) that holds the horn at the proper focal point. The mast is mounted to the center of the dish by sliding it over a stub of metal pipe secured to the center of the dish with a pair of pipe-mounting flanges. The PVC mast is slit where it slides over the pipe, and the entire mast assembly can be moved both up and down the pipe to optimize focus and rotated to match polarization. Once the proper orientation is achieved, the mast is locked into place with one or more hose clamps.

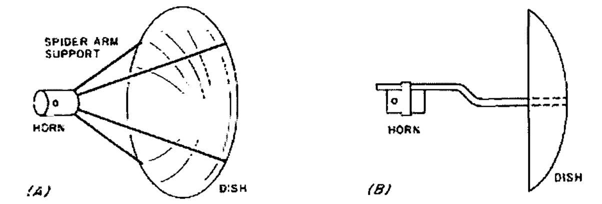

Fig. 1. Two common methods used to mount cylindrical feed horns. (A) shows the use of spider-arm support rods—an efficient system, but difficult to construct; and (B) shows the use of a support pipe, offset to accept the horn. This system is easy to construct but is unsightly and somewhat inefficient.

If the mast is quite long or the feed horn is heavy, the assembly can be guyed with dacron lines run from the corners of the G-10 mounting plate to screw-eye and turnbuckle assemblies attached to the rim of the dish.

Construction

The diagrams in Figs. 2 and 3 provide most of the information required, but a few points are worth discussing. First, the mounting plate *must* be attached to the PVC mast using nylon mounting brackets and hardware. If you use metal here, you will eliminate most of the advantages of this particular mounting scheme. The brackets and hardware can be obtained from hobby shops that carry supplies for radio-controlled airplanes.

The PVC tubing is cut about four inches shorter than the focal length of the dish. This permits the focal point to fall about 2 inches (5 cm) into the horn while

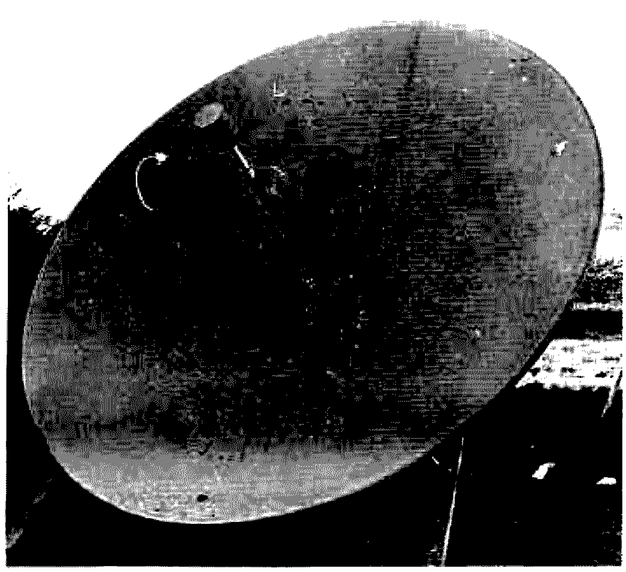

Photo B. Pictured here is a 10-foot (1.3 m) dish, complete with horn feed, used for GOES satellite reception. With a small dish in the 4- to 6-foot range, and depending on its weight, the horn may not require guying. With a larger dish of the sort shown here, the long mast does need dacron guys.

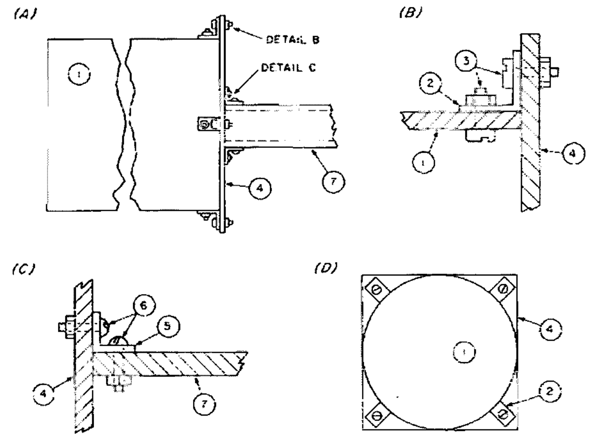

Fig. 2. (1): feed horn; (2): metal mounting brackets; (3): 6-32 pan-head hardware; (4): G-10 fiberglass mounting plate; (5): nylon mounting brackets; (6): 4-40 nylon hardware; (7): PVC pipe mast. (A) General view of the relationship of the cylindrical feed horn, mounting plate, and PVC mast. (B) Detail showing the attachment of the horn to the plate using metal brackets and 6-32 hardware. Use pan-head screws with the heads inside the horn to minimize metal protrusions into the cavity. (C) Detail of the attachment of the mounting plate to the PVC mast using nylon *brackets and hardware. (D) End view of the horn, looking toward the dish, showing the relationship of the metal mounting brackets to the corners of the square G-10 mounting plate.*

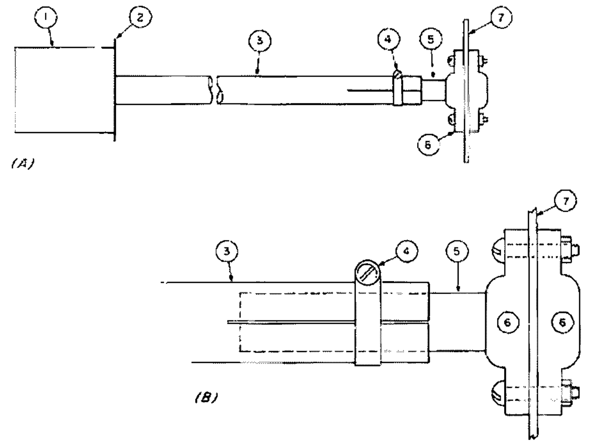

Fig. 3. (1): horn; (2): G-10 plate; (3): PVC pipe mast; (4): hose clamp; (5): steel pipe stub; (6): pipe mounting flanges; (7): dish surface. (A) The general relationship of the horn mounting-plate, PVC mast, pipe stub, and the pipe flanges used to secure the mast to the center of the dish. (B) Detail showing the attachment of the mast to the dish surface. Two pipe flanges, one on either side of the dish center, are used to provide rigidity. A pipe stub, which may be up to 1/3 of the dish focal length, is used to provide support to the mast. PVC and steel pipe sizes should be chosen so that the steel pipe is a slide-fit in the PVC pipe. The PVC mast is slit at the dish end and tightened down with one or more hose clamps.

still permitting about the same distance for downward movement of the assembly if required for focusing. The following assembly sequence should be followed:

(1) Mount the nylon mounting brackets to the end of the PVC mast. Doing this first lets you get pliers or fingers down inside the mast to tighten the hardware!

(2) The mounted brackets then can be used as a guide for marking the G-10 plate which can be drilled then and mounted to the end of the mast—again, use nylon hardware!

(3) The brackets (aluminum, brass, or other metal is OK) then may be mounted to the horn and the horn attached to the plate. In mounting the horn brackets, be sure to use pan-head screws with the heads inside the horn and the nuts outside. This minimizes metal protrusions into the horn which could distort the wavefronts in the waveguide horn assembly.

(4) The entire assembly is placed over the pipe stub, its position optimized, and then everything is tightened up with hose clamps.

If guying is required, it can be installed now. In the case of an antenna used for support of a satellite ground station, the guying system can perform a fine-tuning function in the alignment department. Large dishes (8-10 feet or larger) are quite critical in orientation, and it often is possible first to horse the dish into the best possible orientation, and then to use the guy adjustments to shift the horn position laterally as required to peak the signal level. If large displacements of the horn are required (more than an inch or so), it means that the dish was not aligned properly. The horn should be centered (guy lines of precisely equal length) and the alignment of the dish altered to bring up the signal. You then can fine-tune the alignment with the guy cables.

Since the pipe attached to the dish can provide some rigidity to the PVC mast, it is useful to know how long the pipe can be without absorbing significant rf. This is dependent upon dish focal length. Generally, if the pipe is about one-third of the focal length, it will not affect the signal level. This is because the horn obscures the center of the dish and the converging wavefront from other areas of the dish will not intersect the pipe as it would if the pipe were much longer.

If desired, you can run a bead of silicone seal around the edge of the horn where it attaches to the G-10 plate, to provide some weather-sealing. This is usually most important with antennas used for point-to-point ground service, as the horn is not likely to pick up water or snow when pointed up in the air at a satellite! In the latter case, it is not even necessary that the plate cover the entire opening to the horn. I have built several feed assemblies where the plate was simply a wide strip across the opening of the horn. In making an inspection of one GOES satellite installation, however, I discovered a nice wasps' nest in the feed horn! I suppose that if a bird decided to use the horn for its spring nesting ritual, it might result in some puzzling signal-level anomalies! It probably is best to seal up the horn—if only to exclude the local wildlife!

This mounting scheme has been used in a number of GOES satellite ground station installations, with antennas ranging from 3 to 10 feet in diameter, with excellent results in all cases. Cylindrical feed horns are certainly simple to construct, and they provide fine results. I think you will find that this mounting system will make them just as easy to use! ■

Antenna Tuning Joy Revisited

—remember the Tektronix 190B?

Amplifying K5QY.

Dave Brown W9CGI
RR 5, Box 39
Noblesville IN 46060

In the May, 1978, issue of *73 Magazine* there was an excellent article by Dick Sander K5QY entitled "Make Antenna Tuning A Joy." The article described the modification of a Tektronix 190B constant-amplitude sine wave generator. It is my intention in this follow-up article to add to Dick's comments and ideas and give a few basic details that he left out on the generator itself.

I can testify to the long-term worth of his unit, because I did the same modification 2 years ago. It has proven to be worth at least a hundred times the time spent on it. When I say I did the same modification, like any ham, I have to add an important word—almost. It is additional information and some of the ways I did things as a VHF ham that I believe will be of additional value to readers.

To keep this as short and to the point as possible, I'll first cover the additional specifications you may find of interest. We both started off with the 190B. This unit will run on 105 to 125, or 210 to 250 V ac, with a very slight wiring change similar to Heathkit® equipment (change jumpers, etc.). Further, it runs fine on 50 to 400 Hz. The latter part may not seem important, but I have found that I can use part of an old 6 meter AM mobile power pack unit that was designed to put out around 250 V dc. If you take out or disconnect the dc portion (mine was shot and burned up, anyway), you get, from the ac portion, about 230 V ac and 360 Hz, in my case. The 190B requires about 100 W on 120 V ac, 60 Hz, but the power pack only warms to the touch after about 30 minutes of use. Just a thought for those of you who really must be portable and dc only.

The gear is quite compact and portable compared to some of the older tube-type bench or rack-mounted equipment. It measures only 9-3/4" wide, 13½" high, and 11" deep. Its all-aluminum alloy construction gives it a total weight of only 24 pounds, so it is no surplus boat anchor.

The frequency indication specification for the dial readout is quite good at 2%. This is nice, even if you use the generator only as a generator, but invaluable if you modify it, as Dick and I did, into an antenna bridge.

The output amplitude is continuously variable over a 40-mV-to-10-V peak-to-peak range. Looking into a 50-Ohm load, you have 5 volts peak (times .707 for rms volts). Square that result over a 50-Ohm load, and indeed you have an output of about 250 mW.

This brings out the only point I question in Dick's article. I am a QRP power nut and a VHF/UHF ham. I often have worked another ham 63 miles away with only 16.5 mW on 6 meter CW. That's no great feat, but it all started by accident and has continued using the same setup: my transmitter coupled to a light bulb dummy load in the basement! All I am driving at is, while this may be the handiest device you have ever built for antenna work, remember: You are radiating! Use the minimum on-air time you need for antenna pruning and try to pick non-peak hours in your locale—especially on VHF.

The original ouput meter read the output peak-to-peak volts at that funny-looking connector your unit will come with and is accurate only to ± 10% of full scale. This is really no problem in the modified version, as the absolute value of forward power (voltage) is not important as long as it will drive the swr meter to full scale in the forward mode. Dick mentions changing to a plain voltmeter with a different scale from the original and using a chart supplied by him in the article to calculate vswr. I went one better, I think, and it is by total accident that we were working toward the same general ends at nearly the same time. I found the meter for the Heath VHF wattmeter (HW-2102) to be a great replacement in the $15 range, as it has a direct reading scale for swr. You can ignore the power out-

put scales! I used the bridge basically out of the Heath wattmeter, but have constructed Dick's, too, and either seems to be fine for my VHF work. If you are HF inclined, stay with Dick's resistive version. The Heath meter has a white-on-black scale that is both very attractive and easy to read out in the bright sunlight.

If you contemplate operating at the stock upper limit of 50 MHz, for 6 meter work, by all means use an N-type (50-Ohm) panel-mount female connector to replace the weird little output connector on the front panel of the 190B. Dick used a UHF-type connector here, which is fine at HF frequencies. Unfortunately, due to the huge demand created by the CB market, some UHF connectors are showing up that are UHF in style and name only. Some are OK at CB frequencies and useless at 50 MHz and up. Some would be junk at dc! Why have your worst swr "lump" built right into your test equipment? The extra cost for the N connector is worth it.

If you are *un*fortunate enough to get the attenuator that plugs into that same weird little connector on the panel, do *not* get any ideas about using it for any kind of accurate readings on antennas or any other load with reactance. As you do the band-wandering trick to prune an antenna, as Dick describes, the output impedance of the attenuator wanders all over, and right on the specification sheet it states the following information: Output amplitude is constant ±5% from 30 to 50 MHz, *if* the load capacitance does not exceed 10 pF on the 10-V range. This can be a fixed C, or the antenna reactance! In the 1-V-to-.5-V range, it improves by allowing 50 pF for the same ±5%. Further, it is stated that all changes will be related to, and dependent on, the load capacitance, the length of cables (more on that later), the voltage range in use, and the frequency.

These facts are primarily for those of you who may want to use the generator as a generator with the attenuator. Dick comes right off the generator at the strange little plug you replace with the N fitting, and so did I. Speaking of the attenuator, and to further induce you to go buy a 190B, consider the following.

It's an old flea-market sales trick, but the truth is that you don't want the attenuator unless you intend to outboard the bridge in a box, and swap back and forth between it and the attenuator as the attenuator replacement accessory. So, why let someone run the price up on you by saying he is offering more, or something the unit won't work without? On the other hand, if he doesn't have an attenuator to sell with it, you may succeed in driving down the price by screaming that you must have one!

Fair? It all depends which side of the flea-market table you are standing on at the time, and I have spent 18 years on one side or the other. *"Caveat emptor,"* no doubt, has a seller's corollary, too, and rightly so. The only good deal is where both parties feel they have a bargain—so bargain away!

Before we get away from the specifications on the stock 190B, there is one more thing you should know. If you are working with wideband or multiband antennas (log periodics, discones, trap dipoles or verticals, etc.), you should know that there is *no* specification made for the harmonic content of the 190B! I heard of a case where it was typically less than 5%, but that was a new unit in perfect shape.

If you are going to use your unit seriously, then it would pay to at least spot check it at your points of interest. Even a simple check on a shortwave/allband-type receiver will give you a good idea of where the unit is at. For instance, set the generator up on 7 MHz into a 50-Ohm resistor, with enough leads to radiate a little, and drive the generator up to where the S-meter reads S6 to S9 depending on the linearity of your particular receiver's agc system. Tuning the receiver to 14, 21, 28 MHz, etc., should produce readings in the range of S1 or at least as low as the meter reads, with the receiver input terminals shorted by a 50-Ohm resistor (or proper load to match receiver input impedance).

As for the unit you are looking for, I assume you are not rich enough to see Tektronix for a new one (and I doubt if they still even build it), and the used gear catalog prices are still quite high and are aimed at the small business user. This leaves the hamfests/flea markets. I mention this because the unit is easy to open up so you can look at the condition inside. You can plan on cleaning up a little dust, but beware of anything that resembles saltwater corrosion (white, chalky, lumpy), extreme rust, or missing, bent, or battered shields or covers. You want a piece of test equipment, not junk.

I got a real bargain on mine—fully working and intact, for $20, from a man who knew not what he had!

I sprayed over the slightly-scratched case with a forest green by Rust-o-leum, which is great for equipment you want never to rust or corrode. Besides, this is a nice match for the Heath meter, which has a black face and green plastic bezel, and it contrasted nicely with the brushed-aluminum panel.

My next modification will obviously be to get higher frequency operation out of this wonder of wonders. Even if I get a sudden interest in the low bands and get my Advanced license, I don't really need the .35- to .75- and .75- to 1.7-MHz bands. The 21- to 50-MHz band on my unit does make it usable on 6 meters, but a bit of coil adjustment may be required on some you might purchase. If you have to juggle, my suggestion is to move the whole band up by 1 MHz and recheck the tracking. Use the allband receiver again to align the tracking by adjusting C on the high end and L on the low end until the dial tracking is as close as possible.

That wraps up my way of attacking the 190B and achieving the joy Dick mentioned in his title. I got my first exposure to this instrument at work and know it is a good one. I kick myself for not seeing the full LC impedance bridge Dick goes on to mention, but you can bet I am working on trying it soon. If anyone has any ideas on putting the higher bands into this gear (at least 2 meters), please write it up or contact me.

I promised to cover more on the capacitance effects, cables, etc., and I left it for last because it really does not pertain only to the 190B. Dick touched briefly on using the modified generator to check old coaxial cable. A lot of bridge, swr, and loading problems can be eliminated or minimized by using the same general techniques. By using a *new* piece of RG-8 foam, commercial grade and quality (not the CB-grade junk), and cutting it to ½ wavelength or even 1 wave-

length at the desired and most-used frequency (allow for the velocity factor of the cable), you can make a simple swr transformer. As you know, voltage and current repeat themselves in the cable at ½-wave intervals, and, therefore, so does the swr reading. By first cutting the coax close to the calculated length, but slightly long, and shorting out the far end from the generator, you can determine the exact resonance of the coax just like an antenna. When you have it properly trimmed for the frequency chosen and connectors are on it, hook it up to a good 50-Ohm load like a Heath "Cantenna." Your resonant point should remain the same (matched resistive load) and the swr should be 1:1. If the coax is good and cut to the correct length and the load is really 50-Ohms resistive, any remaining swr is the combined result of bridge unbalance, coax connectors, and coax reflections (bumps or imperfect cable); all, in total, should be very small. Note it on the generator panel for future reference if you can't eliminate it. If the unit won't get 1:1 with a perfect load, it will never get it with the antenna under test. A digital swr meter readout would make the unit perfect, and I am working on that very thing right now.

I can only repeat Dick's closing statement that the 190B in modified form is the "... most practical and economical antenna tuning aid I've used in my antenna experimentation ...," and I hope my article will help make Dick's article and a great piece of gear more useful to all of you who try it. Drop me a note and an SASE if you have any problems with what I've written here.■

Modern Solid-State Equipment Design: A Better Way

—sorry, tube fans

L. B. Cebik W4RNL
5105 Holston Hills Road
Knoxville TN 37914

Most books and articles on solid-state design for rf stress the parallels between transistor/FET circuitry and tube circuitry. These parallels are accurate enough as far as they go, but they also are misleading. To the average reader, they imply that equipment design using transistors or FETs should parallel tube equipment. In many ways, especially for the amateur, this inference is wrong and accounts often for why we never get some piece of equipment to work.

In this article, I want to compare old-style tube techniques with some tried and proven principles for transistors. These principles are not for the engineer or the commercial manufacturer; they are for the home builder. They call for some changes in the way we think about building up a fairly complex piece of rf equipment. In this review of the similarities and differences between vacuum tubes and transistors, all of the ideas I give will be commonplace. But when set next to each other, they suggest new ways of doing things for the ham constructor.

Changing an old way of thinking is probably the hardest thing for any of us to do, but if you think through these ideas, and then take a look at some of the projects that have appealed to you (transmitters, vfos, receivers, and the like), you will be in a position to make the change. No longer need you believe that you can never get a bunch of transistors to do what the original author got them to do. By some simple redesign work, you can have confidence that you can do it, too—and maybe do it better.

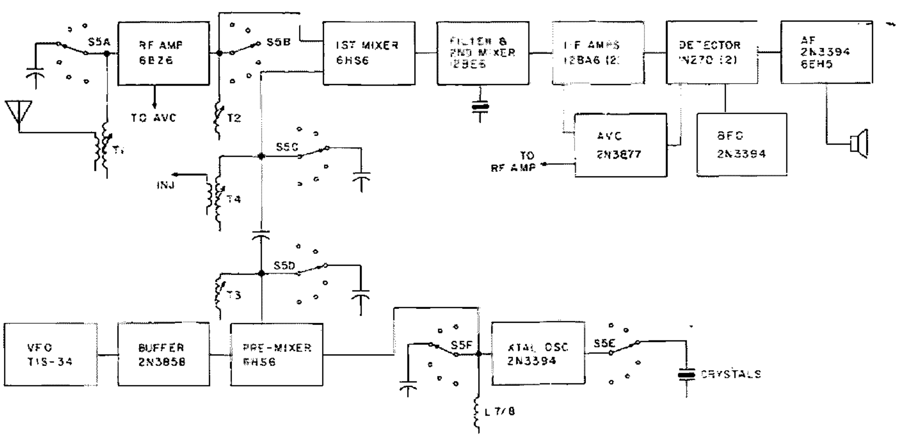

Fig. 1. Simplified block diagram of a tube-type receiver, adapted from the R-4B and drawn to show the methods of switching rf-tuned circuits for each stage prior to the mixer, i-f, and af stages. Note that a 6-pole, 6-position switch is required to accomplish band changes. Although the method of mixing frequencies to reach the i-f differs among manufacturers, the relationship of band changing to the various stages is common to almost all of them. In this late model tube-type receiver, some solid-state devices have been introduced. Tuned circuits have not been terminated because of complexities in the full schematic of this Drake receiver.

Designing with Vacuum Tubes

The design of rf equipment using vacuum tubes has changed little in the past forty years. Perhaps the major change—outside of improved tube construction and improved individual circuits—has been the introduction into amateur gear of the heterodyne vfo system of frequency control. The 5- to 5.5-MHz vfo heterodyned to the ham band of choice has eliminated most of the prob-

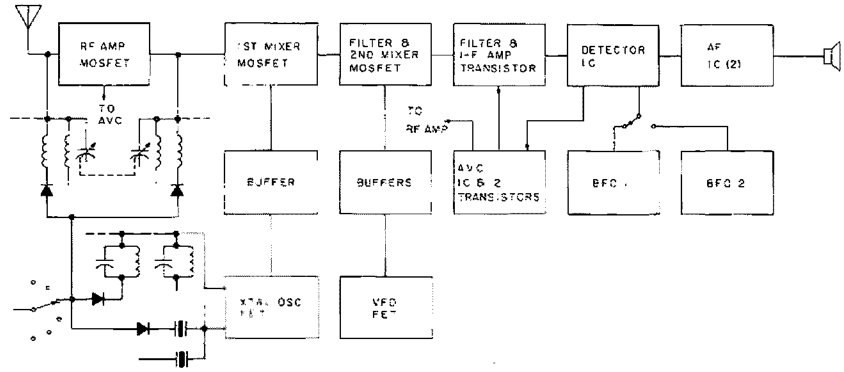

Fig. 2. Simplified block diagram of a recent commercially-manufactured solid-state ham-band receiver. Note the similarities to Figs. 1 and 3: All use single devices in the critical rf circuits and switch-tuned circuits. Problems of lead length and switch expense are solved in this design by the use of a diode switching system. The switch handles dc, and all rf remains on the printed circuit board. This, plus the use of a high-impedance device, the MOSFET, minimizes some problems of multiband operation, but not all. Compare this to Fig. 4 in which the rf circuits are optimized for one band. This diagram, with modifications for simplicity, is based on the Heath HR-1680. Both the HR-1680 and the Drake R-4B of Fig. 1 are fine receivers in their respective price classes, but their design philosophies may not be best for the ham builder.

lems inherent in the bandswitching vfo or the vfo multiplied to frequency. The instability of vfos required to cover a ten-to-one frequency spread, as well as instabilities introduced by switching tuned circuits, held back single sideband and serious communication on VHF frequencies for many years. Likewise, when we used frequency multipliers, we also multiplied any flaws in the vfo.

Other than this, equipment design has changed little. To illustrate this fact, let us look at Fig. 1, a simplified diagram of a straightforward receiver. In the diagram, I have shown most of the switching circuits, but omitted other circuit details. In both amateur gear and commercially-made gear, this basic system design has been standard. With vacuum tubes, there are good reasons for this standardization.

Notice that most of the switching involves the replacement of one frequency-determining circuit for another. To switch bands requires the exchange of several tuned circuits, as well as a change of crystals. Here are some of the basic reasons for working out the system design in this way:

1. The system permits the least number of tubes, which is desirable because, (a) tubes are large—they take up space; and (b) tubes are heat generators, and this system minimizes heat.

2. Tubes, being high-impedance devices (high especially when compared to the frequency-determining circuits associated with them), usually require little attention to perfect matching, and are, therefore, reliable for a given biasing arrangement over a large frequency spread.

3. Tubes are large compared with tuned circuits and switches (especially at low power levels), thus making it more economical of space and cost to switch tuned circuits.

4. Tubes are inherently expensive; for receivers, five tubes can cost five times as much as one five-position switch section.

5. Tubes, as they come into the hands of either the commercial manufacturer or the building amateur, are reliably similar, varying well within a 20 percent range in characteristics within types.

6. Most modern tubes have input and output capacitances which are small enough to present no design problems in the 3- to 30-MHz range (unlike the old '24 and '27, so popular around 1930).

Fig. 2 shows a simplified diagram of a relatively recent piece of ham gear. The diagram has been drawn to bring out the similarities between tube and transistorized gear commercially available. Note that the switching arrangement is not materially different from that of Fig. 1. Single solid-state devices are used at each stage, and the frequency-determining circuits are switched with the traditional bandswitching arrangement.

Fig. 3 shows a simplified diagram of a piece of equipment taken from a recent ham publication. Notice that it, too, uses the very same system of switching and design.

Unless one is an engineer or has access to select components, circuit design of this order is difficult to replicate. Among the reasons for the difficulties we face in making a complex circuit work just as some article claims are these:

1. Transistors may vary greatly in characteristics from a design center. This problem is aggravated by the fact that hams generally have access to culls, hobbyist-grade devices, or surplus, any of which may vary by an even greater extent. For this reason, the amateur designer must do his own selection from among the batches of 20-cent transistors he has on hand, and he must be willing to rework bias and drive circuits to make the device work as it did in the original. To expect a complex group of transistors to perform reliably over a wide frequency range under these conditions often strains the imagination and the experimenter's patience.

2. Other materials of the system of circuits may not be available, and the amateur designer substitutes what he has on hand. He may use surplus or junk box coil forms or toroids of dubious ferrite or iron content. What this may do to circuit Q is anyone's guess. Capacitor quality is another overlooked problem, one aggravated by the uncertain history of the short lead parts in the junk box.

3. Those who attempt to reproduce equipment shown in articles and books often lack the test equipment necessary to perform the right measurements so as to find out what in a circuit may not be working correctly. Among our common building practices are these: tapping coils just as specified in the article, rather than determining the actual impedance to be matched; assuming that the bias circuitry of a transistor provides the correct parameters, rather than measuring actual currents drawn; and assuming that proper

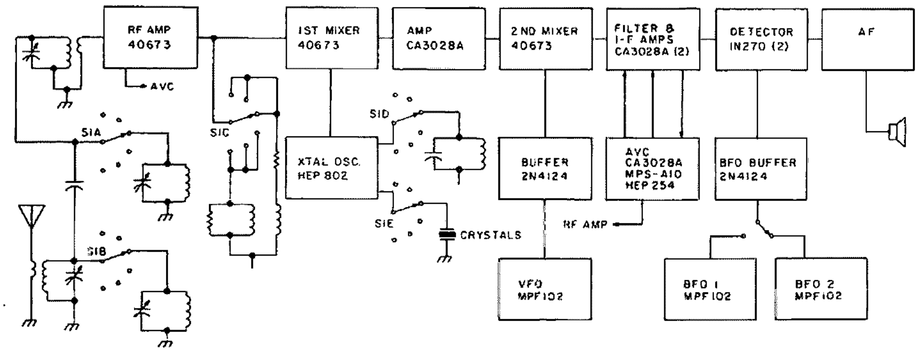

Fig. 3. Amateur receiver (simplified block diagram), adapted from the 1974 Handbook. *This particular unit was originally built in two pieces: a basic receiver from the CA3028A amp through the af board, and a converter section for all the HF bands. Note the attempt to use high-impedance devices—MOSFETs and JFETs—to minimize problems with switching-tuned circuits. Even so, a long five-section ceramic switch is required. Among the positive design features of this receiver are the provision of avc voltage to the first rf stage, upward conversion to minimize birdies, and switched bfos. Front end compromises would have been further minimized through the use of separate converters for each band.*

drive levels are present from stage to stage, rather than measuring rf voltage.

Add up all these conditions and practices, plus perhaps a dozen others peculiar to certain kinds of builders, and it is little wonder that the amateur who tries to build a receiver designed like one in Figs. 2 and 3 has little luck making it work.

Now, it is not reasonable to believe that every ham builder will spend the money it takes to obtain select components or to set up complete test facilities. Nor should we expect that in the near future, circuit reliability will increase to make every wide-range rf system easily repeated. Does this doom the amateur builder to failure? No, not if we change some parts of our design philosophy.

Some Useful Things to Remember about Transistors

Transistors and FETs resemble tubes in these two main ways: First, they may be operated Class A, AB, B, or C (plus some other ways to which experimenters have given new class names); second, any element may serve as the common element, so that we have corresponding common cathode/emitter/source amplifiers, common grid/base/gate amplifiers, and common plate/collector/drain (cathode/emitter/source follower) amplifiers. Knowing this much is important in determining the details of individual circuits. However, transistors also have significant differences from tubes, differences which are very important in the development of a design philosophy for complex pieces of equipment. As we did with vacuum tubes, let us set them out together:

1. Transistors and FETs are very small and take up little space on a chassis or circuit board. About fifty of them might fill the space taken up by one miniature tube and its socket. *Principle: Unless we are interested in the greatest degree of microminiaturization, it really does not matter how many transistors we use, so long as each is used well.*

2. Transistors and FETs create little heat at low powers, i.e., under a Watt. *Principle: No matter how many low power stages we use, heat will probably not be a factor in either the stable operation of a circuit or in the lifetime of the circuit.*

3. While MOSFETs are very high input impedance devices, transistors especially, and to some extent JFETs, will have lower impedances which require attention to matching. There are, of course, many more wide-range circuits for FETs than for transistors, which require little attention to matching. *Principle: For transistors, at least, matching to the individual device is still best.*

4. Transistors, especially in the hobbyist class available to most ham building, will vary in characteristics and require attention to operating levels. *Principle: Bias levels for transistors may need to be fiddled with, and may not work consistently across wide frequency excursions.*

5. Transistors and most FETs are cheap; to buy them five for a dollar is not uncommon, and even specified types like the popular 40673 or MPF 102 cost under a dollar. *Principle: The number of transistors and FETs in low power stages is not likely to make a ham project too costly to build.*

7. Compared to other components, such as switches, coils, and capacitors, transistors and FETs are small and inexpensive, and their associated biasing resistors may cost a nickel or less apiece. *Principle: It is better to substitute small, inexpensive components for big expensive ones wherever circuit reliability can be maintained or improved.*

From these points of comparison and their associated principles, you can see a design philosophy beginning to emerge. Since it is often (though not always) necessary to tweak a circuit up for an individual frequency band, and since the necessary components are cheap (and for other reasons which will become obvious in a few more paragraphs), it is better for the ham to build rf systems of circuits for one band at a time, and then to switch them in and out as needed, rather than to use the tried and true (for tubes but not necessarily for transistors) method of switching frequency-determining components. Not only can this method assure better circuit reliability, but it can also simplify the process of building, provide operational equipment before the entire unit is functional, and save money for the builder.

Some Examples

Let us look at a couple of examples of this design philosophy and see how they work out in practice. First, go back to the receivers of Figs. 1, 2, and 3. Fig. 4 shows how the receiver can be designed using the principles above.

The revised receiver employs converters for each band except 80 meters. This is a scheme used extensively and, with the exception of separate converters, goes as far back as the Drake 2 series of tube-type receivers. The i-f frequency is a matter of choice in accord with the design objectives, and can be a function of up or down conversion. The

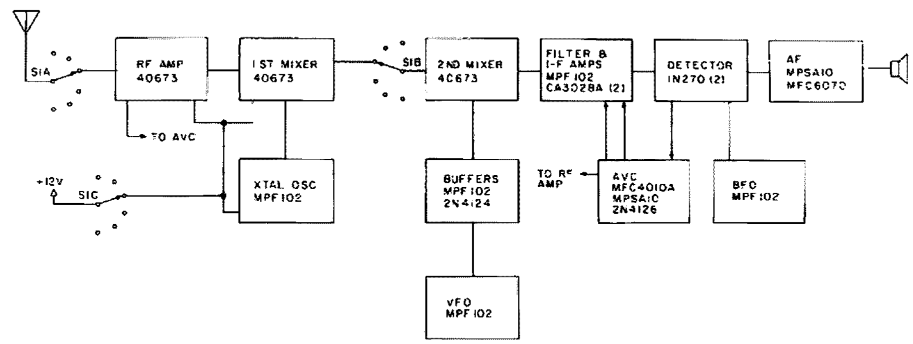

Fig. 4. Block diagram of a receiver most closely meeting the design principles enumerated in the article. In general, this is part of WA1JZC's receiver in the 1978 Handbook, *with some alterations. Unlike the original, avc is shown for the rf amplifier. My personal choice calls for different circuitry, but this design is readily available for study by the prospective home builder. Note the simplified switching of rf circuitry. The originator in fact optimized converter design for each band using JFETs in a grounded-gate circuit (except on 80, where he omits the rf amplifier) and a 2N4124 crystal oscillator. His commentary is worth repeating: "Separate converters were incorporated to eliminate the need for complicated bandswitching, and also to permit optimization of circuit values for each band of interest. The system used in this receiver calls for switching of only dc and 50-Ohm circuitry. Low-impedance switching eliminates problems caused by long switch leads. Switching at high impedance points, which is the usual technique in multiband receivers, can impair the quality of the tuned circuits and makes isolation of critical circuits more difficult." (See pp. 280-281.) Although some of these problems can be overcome by the diode-switching techniques of Fig. 2, optimizing performance and being able to assure full frequency range repeatability with home construction techniques require adoption of something similar to the design philosophy of this receiver.*

main design features to note are these:

1. No device operates at more than one frequency or band, thus allowing for optimization of all parameters. Among these are gain, bandwidth, oscillator-output level, stability, and avc action. For each converter, bias values, coupling capacitors, LC values, and the avc voltage-divider network can be juggled either to provide equal gain for all bands or to emphasize or de-emphasize some bands. (Maximum gain for 80 and 40 meters usually means more noise than signal.) The remainder of the circuit is standard, in the sense that almost all receivers operate i-f and detector stages at one frequency.

2. Note the switching system. Converters which are not in use are not powered, thus eliminating some potential birdies. Switching, however, requires only a three-pole switch, one each for antenna input, converter output, and Vcc. Moreover, by using shielded signal leads (and shielding the power lead is not a bad idea) and minimal inter-section shielding of the switch, the entire switching network can be made very compact. In some receivers using similar schemes, I have seen retained the classic long switch, running from front to rear on the chassis. It is quite unnecessary.

3. The avc system employs resistor-divider sections to limit or expand voltage excursions so that the avc action is controlled for each band. Many receivers of this design omit avc to the converters, relying upon the basic receiver sections to do the job. Given the gain of the converter sections, overloading can become a problem. Tailoring the avc action to each converter solves the problem. Avc voltage can be switched or not, depending on circuit design; it should be switched out unless the converter, when not in use, shows an open circuit to the avc voltage. Otherwise, it will load the avc system. A compact fourth pole on the bandswitch solves this potential problem.

4. Unlike many handbook designs, there is no need to make each converter identical. Single-ended rf stages operate well on all HF frequencies with MOSFET devices, but experimentation with a pair of grounded grid amplifiers in cascade, or with cascode circuits, is worthwhile. Moreover, one can try push-pull circuits, since the usual mechanical problems of band changing with balanced LC circuits are not present. I am often amazed at the lack of experimental ingenuity which appears in rf designs in the ham journals, despite the large number of possible circuits available for use, and the variety of devices which just might make one or more of them a good performer.

5. The main limitation on this design philosophy is that it does not produce the most compact equipment possible. For subminiature gear, perhaps another method of design should be used, but for home station use, miniaturization is not the ideal situation. The two main physical considerations should be experimental flexibility and accessi-

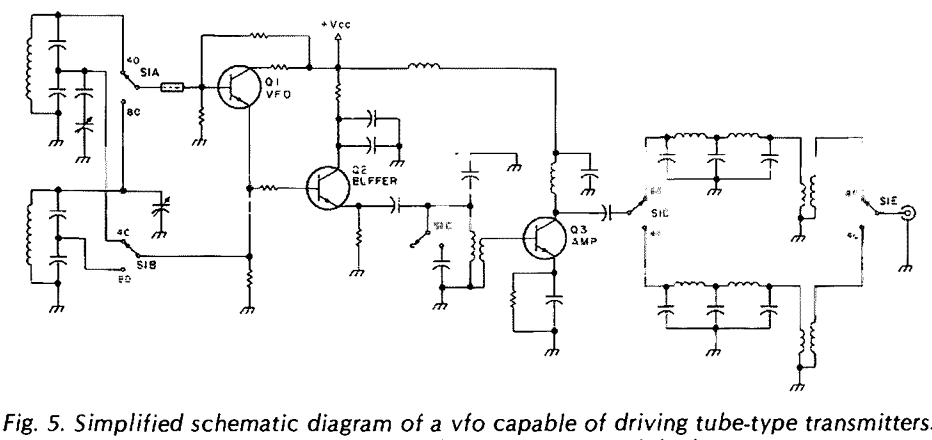

Fig. 5. Simplified schematic diagram of a vfo capable of driving tube-type transmitters. Note that LC combinations are switched by S1A and S1B, while the input to Q3 is tuned by switching a capacitor across a fixed coil with S1C. From the ARRL Handbook.

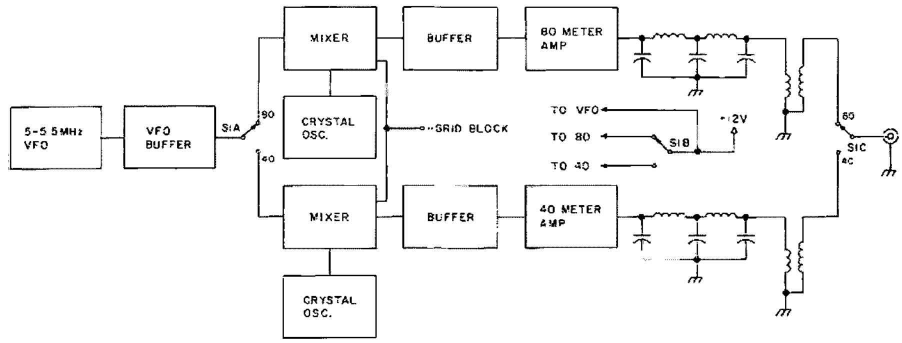

Fig. 6. Block diagram of mixing vfo for tube-type transmitters. Individual circuits are similar to those of Fig. 5. Buffers are untuned. Mixers are FETs with about −4 volts grid/gate block. Note especially the simplification of switching, which allows a single wafer to be used rather than the 8″ switch used in the original of Fig. 5. Notice also that either mixer-amplifier section may be removed for adjustment or experimentation without disabling the vfo completely. Total cost of the "extra" mixer-oscillator-buffer-amplifier devices was under $2.00.

bility, and operating ease. The mechanical size of easily read digital- or mechanical-readout systems is still the main factor limiting miniaturization. Within the size limits of most convenient readouts for main station use, there is plenty of room for the boards for each converter. In fact, many of the imported transceivers, when mobile use is not intended by the operator, appear to be excessively compact both for operating ease and for maintenance convenience. Heat is a constant worry with them.

The amateur designer, therefore, might well take a page from the notebooks of home computer designs. Within whatever case one uses, develop a main frame with plug-in units at every stage, along with space for future, more complex circuits. With careful attention to routing rf paths, you can use plug-in circuit boards or plug-in perfboards. Shielding between most boards is a must. The advantage of this system is that replacement circuits can be developed independently and tried in the receiver, without losing the receiver from service for long and without mechanical alteration to the basic unit. This not only ensures an operative receiver at all times, but also eliminates future mechanical costs for new versions. Your equipment will be as up to date as your latest experiments, however old the case may get.

These advantages accrue not just to receiver design, but also to transmitter stages as well. Fig. 5 shows an 80/40 meter vfo that appeared in the *ARRL Handbook* for several years. Notice that the tuned circuits in the vfo are switched. Note, too, that the input circuit to the power amplifier is changed from 40 to 80 meters by the addition of a capacitor. Neither of these schemes is optimal, and their correction is hinted at by the design itself. The output filters are switched in their entirety. Why not the entire power train?

Fig. 6 shows a simplified diagram of the revised system built for a ten-Watt standby rig using tubes. The 5- to 5.5-MHz oscillator runs all the time. Separate mixer, buffer, and amplifier stages give 80 and 40 meter output. They are built on separate boards and require only a three-pole switch, one each for vfo input, amplifier output, and power. If one desires separate output jacks for each band, one pole of the bandswitch can be eliminated. Tuned circuit and bias values have been optimized for each band. Since the transmitter with which the vfo is used supplies not only the twelve volts, but also blocked grid-keying voltage, the mixers are keyed. Because of the transmitter design, more output was required on 80 than 40, a problem easily solved using this scheme. If I ever use the vfo with another rig, equalizing the vfo output will be no problem either. Despite the fact that the vfo uses an old ARC-5 tuning capacitor, the entire unit fits in a 4 x 5 x 6 case. Obviously, little is lost to compactness by the use of the design principles enumerated here.

The purpose of this article is not to get you to build what I have built. Instead, it is designed to encourage you to build what you want, by showing that there are some basic principles which take the scariness out of complex rf equipment that appears in the ham journals. The basic idea to get rid of is that you have to make a tricky device like a transistor operate all the way from 80 or 160 up to ten meters. Doing your work one band at a time and building your equipment one section at a time not only makes building for the amateur non-engineer possible, but also makes it fun. What you learn from trying new bias values and schemes, or from trying different LC values, will soon give you confidence that you can make almost anything work.

building, and that is to give you my personal prejudices about what test equipment the ham builder ought to have. A VTVM with regular and rf probes is essential—preferably one that has a range of about a volt and a half for reading partial volts. My trusty Heathkit has stood me in good stead for many years. A grid-dip meter for testing LC circuits or for a signal source is also very useful. A VOM for current readings is needed, but it need not be an expensive model. Beyond that, the rest is up to you. Oscilloscopes, frequency counters, impedance bridges, and the like are all useful, but with them I notice that I do not have to clean off my fingerprints nearly as often as I do with other pieces of test gear. Finally, station operating meters for swr, power output, and dummy loads are useful only for some projects. An all-wave HF receiver, however inexpensive and inexact in dial reading, can help a great deal, especially in testing things like heterodyne oscillators. For me, however, the big three are the VTVM (and rf probe), the gdo, and the VOM.

The principles I have given can be expressed in many ways. I welcome additions to the list, and new ideas to improve my own techniques. Hopefully, the ones given here are enough to encourage you to make the move from building station accessories to building your entire station. Then you can use that commercial rig as your standby. ■

Shortened Antennas for 75 and 80

—designs which fit your QTH

Slopers exposed.

During 1975 and 1976, I tested various 75 meter antennas with several ZLs and VKs. This band is generally open from there to the United States during the early mornings (local US time) around 1000 to 1200Z. I have been trying to determine if there is any particular 75m antenna best suited for this 7- to 8-multihop 8000-mile-plus path. There are usually a number of US hams working the ZLs and VKs on SSB between 3775 and 3850 kHz. The ZLs are permitted to work this portion of the band. As the VKs' highest frequency end is 3700, they generally transmit SSB between 3680 to 3695; therefore, split operation must be used with them.

75m antennas tested here during 1975-76 were: several dipoles at various heights (40 to 70 feet); three delta loops; a two-λ horizontal quad at 70 feet; two ½-λs in phase, collinear at 70 ft. (broadside to NZ); several ¼- and ½-λ verticals; a 3-element yagi at 60 feet; and three horizontal monoband dipole log periodics (DLP), one 3-element, one 4-element, and one 5-element, all at 60 feet.

At times, I have had as many as 3 or 4 75m antennas up at the same time for making direct comparisons between the various types. During the tests, the best reports from the ZLs and VKs have been with the log periodics and the yagi. As all of my antennas are supported by pine trees, the maximum height above ground for the horizontal antennas is limited to 60 to 70 ft., or approximately only ¼ λ above ground at 3.8 MHz. These are, of course, fixed-wire beams.

At times, the yagi or the log periodic would be reported as much as 10 dB better than some of the other types being tested. The yagi and the LPs were all beamed west or SW.

The log periodics and

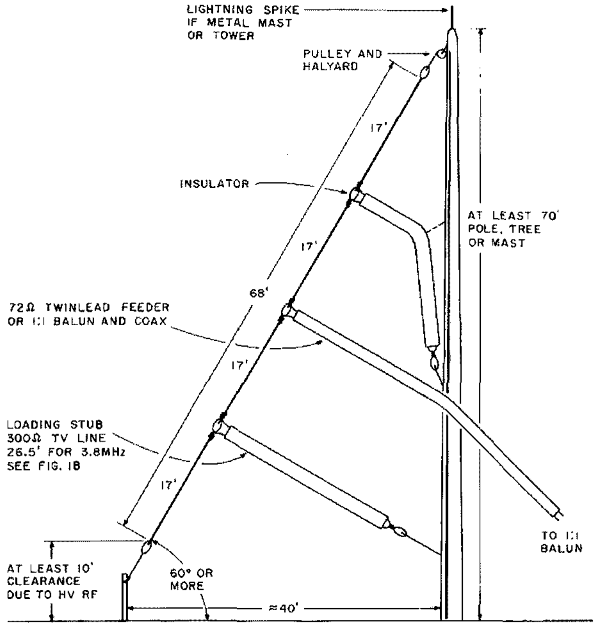

Fig. 2. Shortened ½-λ dipole sloper, stub-loaded.

the yagi, although producing the best reports from "Down Under," are quite large, requiring a width of approximately 150 feet and a boom length of at least 100 feet. The general design of the 5-element monoband log periodic is given in reference 1, Fig. 6, reference 2, Fig. 2, and reference 3, Fig. 4. The dimensions for the frequency range 3.8-4.0 MHz are given by reference 2, Table 1. This LP was supported at about 60 feet by 8 pines.

As an antenna of this size is generally impractical for the average ham on a city lot, during 1977 I tested 75m antennas requiring less space but still giving some gain and more directivity than the usual 75 or 80m dipole or inverted vee when limited to a height of only sixty to seventy feet. These are described in the following.

Shortened Dipole Slopers

During the tests with the ZLs and VKs, it was noted that W2GO, one of the more consistent early morning DXers, uses a single shortened (66-foot) dipole as a sloper to the west with very good reports.

Shortened dipoles using off-center loading coils were well covered by Jerry Hall K1PLP (*QST*, Sept., 1975, page 28). By use of two 40-μH loading coils, the 75m dipole was shortened to 66 feet. This is the type used by W2GO for his shortened 75m centerfed ½-λ sloper, which requires only a single 60- to 70-foot pole, tower, or tree support. It is sufficiently compact to be used on a small lot. This was the type which I selected as being the most simple and compact antenna requiring minimum space.

As I did not have a pair of loading coils as specified in the *QST* article and did not wish to take time to wind them, I used instead two lengths of 300-Ω TV line as loading stubs for the shortened dipole. See Fig. 1(b). As a start, I used 30-foot stubs which resonated the shortened 68-foot dipole at approximately 3.5 MHz. Resonance can be determined by a GDO or by running an swr.

Next, the stubs were each pruned about 6 inches and the resonance was again checked, and then another 6 inches were removed and the frequency checked. This procedure was continued until the dipole resonated at 3.8 MHz. A total of 3.5 feet had been removed from each stub, making them each 26.5 feet in length. These loaded the dipole to the desired center frequency, 3.8 MHz. An swr was then run to determine the usable bandwidth of the shortened stub-loaded dipole, illustrated in Table 1. It will be noted that the bandwidth is quite narrow but usable ±100 kHz covering the DX portion of the 80m phone band.

This shortened or loaded dipole was then suspended as a sloper (Fig. 2) from the top of a 70-foot tree and sloped SW for tests with the ZLs. Although the overall length of the sloper was only 68 feet, it worked surprisingly well, considering its simplicity and ease of construction. It was fed with 72-Ω twinlead connected via a 1:1 balun to a buried coax to the shack.

For a dipole-type sloper to be effective for DX, or rather to have a fairly low angle of radiation, it should form an angle of at least 60° to ground. 70° to 80° would probably be better. It, no doubt, acts as a ½-λ vertical or semivertical. Being centerfed, the necessity of an elaborate ground radial system as required with a ¼-, ½-, or basefed vertical is probably not as important. None was used during these tests. If the slope angle is less than 60°, say 45°, it will probably have more horizontal polarization and higher angle radiation and would become more like a low horizontal dipole with the major radiation lobe at 90° or straight up. In this configuration, it would no doubt show an improvement with nearby stations up to a few hundred miles, but DX operation would suffer.

A second sloper using an old Hy-Gain 40/75 trap dipole (overall length about 110 feet) also was tried, suspended from a 100-foot tree and aimed SW. This sloper seemed slightly better than the original 68-foot stub-loaded sloper. This was no doubt due to greater overall radiating length, more effective height, and an angle of about 70°. It had the advantage of also being usable on 40, though no extensive tests have been made with it on this band.

Phased Slopers—Endfire Array

As above slopers gave fair results considering their simplicity and ease of construction, it was decided to try a 3-element phased sloper (all elements driven) in a log periodic, endfire sloper array configuration. This was constructed by using a nylon line catenary stretched between two high pines separated by about 200 feet and oriented to give a beam at about 225°. The higher, rear tree was about 75 feet in height and the forward tree was about 60 feet high.

As the use of stub-loaders was not desirable due to complications in suspending the stubs so that they would come off at about 90° with respect to the sloper elements, it was decided to use end loading instead of stubs. This was accomplished by folding about 25% of each element end to the rear and securing them to the top and bottom catenaries, as illustrated in Fig. 3(a).

As it was desired to operate this beam centered on 3800 kHz, it was adjusted so that the longest rear element, #1, resonated at 3.7 MHz, #2 at 3.8 MHz, and the short forward element, #3, at 3.9 MHz. The easiest

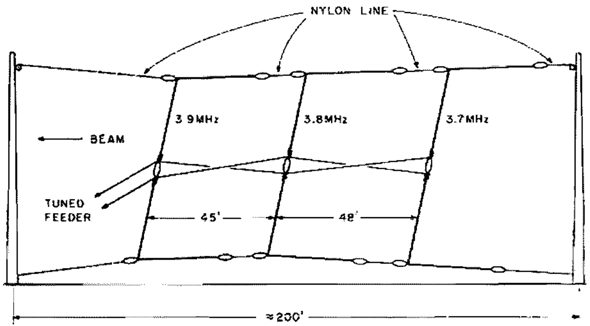

Fig. 3(a). Log periodic phased sloper, end-loaded.

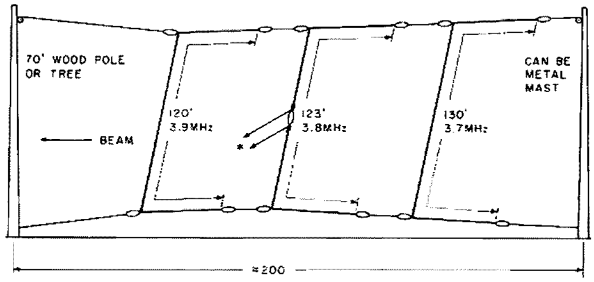

Fig. 3(b). Yagi phased sloper, end-loaded.

way to adjust this is to cut each element slightly longer than its required frequency. Then put temporary jumpers across the center insulators (feedpoints). Secure the ends of each element (folded back portion) to the catenaries and then raise the array to its normal suspended height. At this point, the 2-wire center feeder is not used.

Next, check resonance of each of the three elements separately by holding the GDO near the horizontal section at the bottom of the catenary, and pruning the ends as necessary to the three frequencies, 3.7, 3.8, and 3.9 MHz, as mentioned above. This must be done with the array suspended at its final location due to variations of resonance depending on the height of the three elements above ground. These three frequencies were selected so that the completed antenna would be centered on approximately 3800 kHz, and also to allow the array to operate as a log periodic.

Once the three elements are tuned, the array can be lowered, the jumpers across the three center insulators removed, and the 2-wire open feeder or phasing line connected as shown in Fig. 3(a). Note the transposition required for the array to perform as a log periodic or an endfire array. Each element must be out of phase with its neighbor, as required of any log periodic. The construction of the feedline is presented by the articles in references 1, 2, 3, 4, and 6, covering log periodic wire beam construction, and will not be repeated here.

A large array of this type for 75, even though using only 3 elements, must be assembled and tuned on site for its particular surroundings and height above ground. Table 2 is overall swr covering 3.5 to 4.0 MHz, after adding the center feeder to the array. It then centered on about 3.7. However, as the swr at 3.8 was only 1.25:1, no further changes were made since the beam was usable between 3.6 to 3.9 MHz.

Although this phased-sloper log periodic was only tested for about one week, it appeared to have gain and directivity as hoped. During one of the tests on 3808 kHz, Bob Tanner ZL2BT advised that it was about the same as the 3-element horizontal yagi at 60 feet which I was using at the same time.

The main advantage of the above phased sloper is that only two trees or masts are required, as compared to 6 or 8 necessary to support the 3-element yagi or an equivalent 3- to 5-element DLP. Further, the phased array, being primarily vertically polarized, should have a lower angle of radiation. Since the radiating elements are semivertical dipoles (centerfed), a ground screen or counterpoise was not used during the tests. Although the length requires about 200 feet of mast spacing, its width is less than 1 foot, compared with the 150-foot width of a 75m dipole log periodic or yagi.

For those who prefer yagis, the same 3-element sloper could, no doubt, be arranged as a 3-element yagi by deleting the open wire center feeder, deleting the center insulators from elements #1 and #3, and feeding the center of #2 element directly with 72-Ω twinlead or, better still, with an open tuned line. See Fig. 3(b).

The array would then become a yagi with #2 the driven element, #1 a parasitic reflector, and #3 a parasitic director. The yagi sloper array would, no doubt, have a more narrow bandwidth (possibly no more than ±50 kHz) than the bandwidth of the log periodic configuration. I have not tested the sloper array as a yagi, but, on previous tests comparing a 3-element horizontal monoband DLP with an equivalent 3-element yagi, a greater bandwidth was given by the log periodic.

Test Results

Shortened loaded slopers—

From the tests made with ZLs and VKs on these 75m antennas, and also from comparing notes with the previous tests with ZL1BKD during 1975-76, it appeared that the single shortened loaded-dipole sloper was equal to the larger delta loops, 2-λ horizontal quad, verticals, etc., which were tested then versus the large 75m yagi and/or log periodic (horizontal dipole-type) beams. The latter did average out about 10 dB better than the more simple antennas, including the slopers.

Considering the simplicity and ease of building the loaded sloper, and the fact that only one support is required as against 6 to 8 to support my large beams, it is believed the loaded sloper is the least expensive 75m DX antenna and about the only one suited for a city lot except, possibly, a single ¼- or ½-λ vertical, which can be quite expensive if a 60- or 120-foot tower or mast is used and the required 60 feet or more of ground radial system buried. The latter may also be a problem on a city lot.

During the tests, the large beams would show as much as 15-dB increase over some of the more simple antennas, but these differences would vary from day to day. The 10-dB gain over the more simple antennas was more the average.

Comparing the simple sloper with the delta loops, the type with apex topside requires only one high support but needs about 120 feet of space for the lower horizontal section. The type with the horizontal section up and apex down requires two supports spaced at about 120 feet.

Comparing it with the

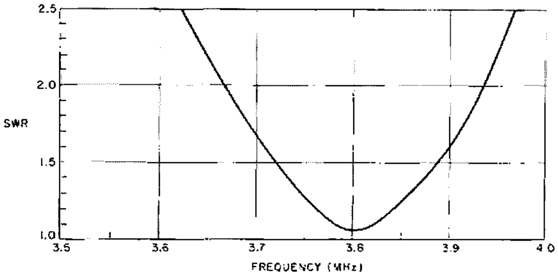

Table 1. Shortened dipole sloper.

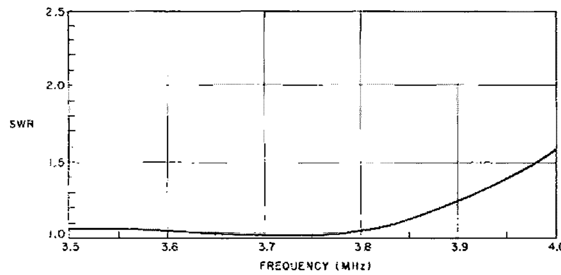

Table 2. Log periodic as in Fig. 3(a).

horizontal 2-λ quad, the latter requires four supports arranged in a square with about 130-foot separation, hardly suited for a city lot. The delta loops and quads also require more wire. 75m phased verticals are also impractical in a small space.

Therefore, the simple loaded-dipole sloper is recommended as a good all-around and inexpensive DX antenna if one does not have an open space of about 150 x 150 feet for a large beam to provide gain. Further, the latter, requiring 6 to 8 supports, also requires considerably more wire, insulators, etc., and a great deal more effort and labor!

For anyone not interested in 75m DX, a shortened or loaded sloper used as a high-angle radiator, either as a sloper at about 45° or as a low dipole at about ¼ λ or at approximately 60 feet above ground, will be a good average short-haul antenna for several hundred miles.

One suggestion would be to have two anchor posts for the bottom end, one to provide a slope angle of at least 60° for low-angle DX, and the other to give about a 45° slope for general short-haul communication.

The 3-element phased sloper—

Although this is a more elaborate beam, having gain, it is not generally suited for a city lot, since two masts with a 200-foot separation are required. It does have an advantage in that very little width is required, but it does require considerably more wire, insulators, and labor to assemble. It did appear to be about neck and neck with the yagi (also being used at the same time) from the ZL and VK reports. It may have been just a bit noisier on reception due to being more nearly vertically polarized. However, I did not have time to determine this for sure. It did make a good showing "down under" when compared directly with the yagi being used then.

A 3-element wide-spaced horizontal log periodic beamed west was set up later, which Bob Tanner ZL2BT advised was the best antenna tested here over the past 3 years.

I might add that, when comparing the various 75m antennas during this period, if the ZL or VK reported a 1 or 2 S-unit or 5- to 10-dB increase or difference between two antennas, the same difference on reception of their signal would generally be noted, as would be expected.

On this multihop 75m path, there is generally less QSB than on the higher bands. When there is fading, it is usually slow, unlike rapid QSB on 20.

For the information of those who do not work 75m DX, the VK and ZL signals generally have a slow buildup about 15 minutes before sunup, when they peak. They remain peaked for 15 to 30 minutes, and then start a decline for 30 minutes to 1 hour after sunup, local time.

As yet, I have not determined if the sunrise peak is due to "gray line" propagation or possibly due to a change in ionization of the F-layer, causing less attenuation at this end or possibly in the last hop (received at this end), thus giving the 5- to 10-dB signal increase which is generally noted at sunup.

It is doubtful that "gray line" affects the US-NZ path since they are in total darkness approaching midnight (sunup here in the east). "Gray line" might affect the W-VK path since sunup here is about sundown in certain parts of Australia.

To get more firsthand information on this, I am now (as of this writing) in the process of putting up two beverage receiving antennas, one N-S and one E-W. These are 2-wire reversible-direction beverages, each 520 feet in length, for use on 160, 80, and 40. Some very excellent data, suggestions, and material have been made available to me by Paul W6PYK for this test, for which I am very grateful. I had previously tested several simple single-wire beverages, resistor-terminated, to improve S/N.

The beverage project was started here originally to try to improve reception which is extremely poor, especially on 75, at this QTH. This is due to very poor ground conductivity, extremely high noise level (both QRN and man-made) on 75, and the fact that it is surrounded by high pine trees (60 to 90 feet) except to the NE and E. They extend for several miles to the SW and W.

For this reason, there is little open space for verticals, since trees higher than a ¼-λ vertical would surround it. There would be some trees separated from them by less than 50 feet, very thick in the direction of the ZLs and VKs. The two single-wire slopers which were tested were suspended from trees in open areas, although there were trees within about 100 feet to the W and SW.

For those who may become interested in 75m DX, there are some very good suggestions on propagation, "gray line," 75m antennas, receivers, a list of 75m DXers, beverage antennas, etc., presented in John Devoldere ON4UN's ham book *80 Meter DXing*, published in 1977. He includes a very complete list of 86 previously-published articles in the various ham publications covering these subjects.

Other Suggested Sloper Designs

In addition to the shortened loaded sloper and the 3-element phased sloper described above, the following are several suggested slopers and phased slopers. I have not actually tried these, but they are described briefly for anyone wishing to experiment or

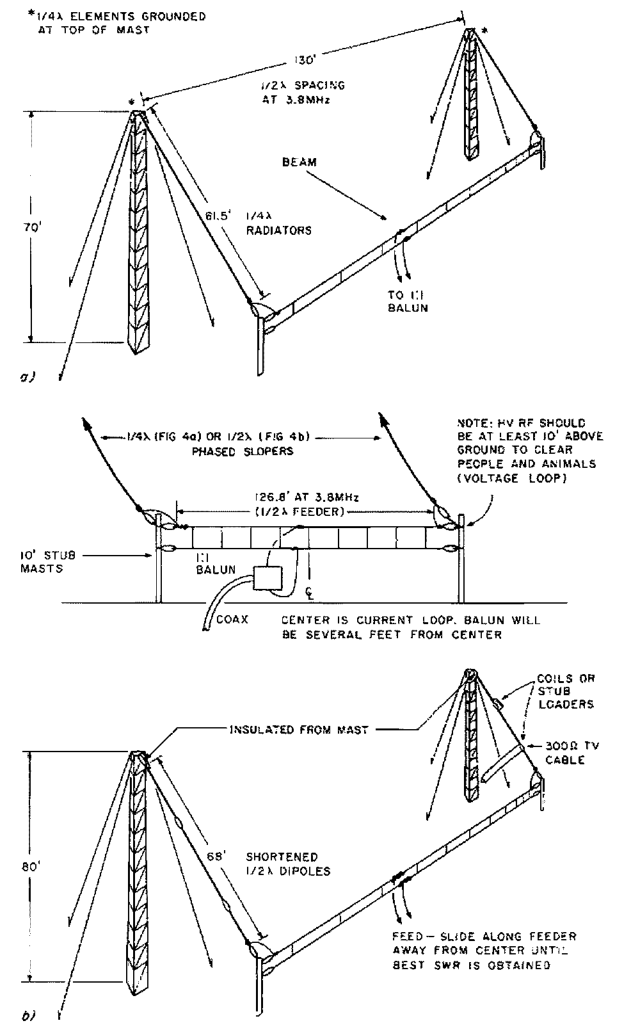

Fig. 4.(a) ¼-λ phased slopers. (b) ½-λ shortened phased slopers.

who is interested in antenna design.

Multidirectional slopers—

If there is sufficient open area around a single high mast or tree, 3 or 4 of the shortened 75m dipole slopers could be used for several directions as per K1THQ's 40m four-direction sloper described in the *ARRL Antenna Book* (Figs. 8-12, page 200, 13th edition). According to his measurements, the forward gain was about 4 dB and front-to-back up to 20 dB. Note that the coax to the relay box must be just over 3/8 λ. At 3.8 MHz, this length would be approximately 63.4 feet of RG-8/U or RG-58/U (VF = 66%), or 74.9 feet of RG-8/AU or RG-58/AU (VF = 78%).

I have not tried this 4-directional sloper, but it sounds interesting for anyone having the room and needing a lobe in more than one direction. If a mast at least 130 feet in height is available, full ½-λ sloping dipoles could be used without loading and would no doubt be more effective. The dimensions would then be about double those given for K1THQ's 40m switchable sloper.

¼-λ slopers—

Not having a tower, I have been unable to test a ¼-λ inverted sloper fed by coax at the top of the tower (with the coax sheath grounded to the tower near the feedpoint). I have worked several on 75 who have reported good results with this type of inverted sloper.

Theoretically, this should be a good antenna, since the current loop of the ¼-λ sloper is topside and generally in the clear. The tower provides a ground plane or acts as a reflector, which should give some directivity. However, this type appears to be tricky (and they either work or they don't). No doubt the ¼ wavelength and the angle between the sloper and the tower are critical, probably affecting the impedance at the top feedpoint, which is probably low. Possibly a matching network between the coax and the feedpoint would help, or possibly the top of the ¼-λ element could be grounded directly to the towers and the lower end voltage fed at the bottom with a tuner or a ¼-λ tuned line used to voltage or end feed, similar to the old Zepp. Using voltage feed at the bottom also saves the length of coax from bottom to top of tower.

I have one friend, YV5DLT, who put up two of these ¼-λ inverter slopers (topfed), one for 75 and one for 40. He said the 75 worked with no problem, whereas the 40m refused to work. I have noted that about 25% of those using the ¼-λ sloper have gotten them to work; the rest had problems or became discouraged if they did not work right away.

Possibly those using these successfully can give some suggestions. Also, the estimated angle of radiation, H-plane pattern, etc., would be interesting.

Dual ¼-λ phased slopers—

Possibly, using two of these side by side, in phase, spaced ½ λ broadside to the desired direction, might be of interest, as per Fig. 4(a). The two ¼-λ elements spaced ½ λ would be grounded topside, as mentioned above. The two bottom ends (voltage loop) would be voltage-fed with a ½-λ open phasing line feeding the ends, so the two ¼-λ radiators will be in phase. The ½-λ phasing line is current-fed, slightly off center directly with the coax or with a 1:1 balun. For 3.8-MHz operation, the two ¼-λ slopers would be approximately 61.5 feet and the 2-wire open phasing feedline approximately 126.8 feet long. This beam requires two 70-foot towers spaced about 130 feet apart and oriented broadside to the desired direction. A few wire reflectors between the towers might improve the lobe in the desired direction.

This array would be similar to the broadside or side-by-side phased slopers described below, except ¼-λ slopers would be used in place of the ½-λ shortened dipoles. See Fig. 4(b).

½-λ phased-sloper or vertical-dipole arrays—

If a mast at least 130 feet high is available, it could be used to support a full ½-λ phased sloper or vertical dipole endfire array. The elements would then be a full ½ λ (no endloading required), thus being more efficient and having greater effective height.

Another advantage of greater height would be the possibility of having the three elements near or exactly vertical, so the array would then become a 3-element vertical (dipole) log periodic or 3-element vertical yagi (whichever configuration is preferred) as was described above under "Phased Slopers—Endfire Array."

With the shortened dipole sloper or multi-element sloper arrays, the loaded elements probably reduce efficiency about

50%, as the shortened radiating portion is only approximately ¼ λ. Their ¼-λ radiating portion should be about the same as the vertical radiating portion of a Bruce array.

The end-loaded sloper array might be considered as a 3-element endfire array, as opposed to a 3-element Bruce array which is a bidirectional, broadside one using ¼-λ radiating elements in phase spaced ¼ λ. The 3-element endfire array would be unidirectional and should give greater gain. The Bruce would, however, probably have a greater null to the sides (180°).

If a single high mast is available, it could also be used as the center support for 3 or 4 separate phased endfire arrays, thus providing 3 or 4 separate beam headings or separate selectable lobes at 120° for 3 arrays or 90° for 4, for beaming N, E, S, or W.

Granger, Trylon, and Hy-Gain manufacture commercial or military fixed-wire monopole and vertical dipole log periodic wire beam arrays of these types for frequency ranges 2.5-32, 3.0-32, 4.0-32, and 6.0-32 MHz. These are recommended for long-haul HF circuits. See the Hy-Gain commercial catalog E, 1969.

Incidentally, if any hams are interested, these commercial wire beams are generally in the $20,000 to $50,000 class. However, this does include an 100- to 240-foot steel tower. A 3- to 5-element vertical (monoband) dipole log periodic for 75m can generally be ham-built for $100.00 or less for wire, insulators, etc., less tower and coax.

Broadside or side-by-side shortened slopers—

Another suggested phased sloper could be the use of two shortened 78-foot ½-λ (loaded) sloper dipoles suspended from two 70-foot masts spaced ½ λ (approximately 130 feet at 3.8 MHz). See Fig. 4(b). The two slopers would be operated in phase with 130 feet of separation. A ½-λ tuned feeder/phasing line would be required for feeding and phasing the two slopers, similar to the dual ¼-λ phased slopers described above in Fig. 4(a).

Better still, if the two phased slopers could be a full ½ λ (requiring two 130-foot masts), they should give about maximum gain to broadside for an array of this type. I believe I have heard of some ham using this type of beam.

There are, no doubt, many phased-sloper-array combinations which can be designed. I again wish to point out that I have only built and tested the loaded sloper of Fig. 2 and the 3-element (end-loaded) phased sloper of Fig. 3(a).

I would appreciate hearing from anyone who is using or has tried any phased-sloper arrays or has any suggestions along this line. ■

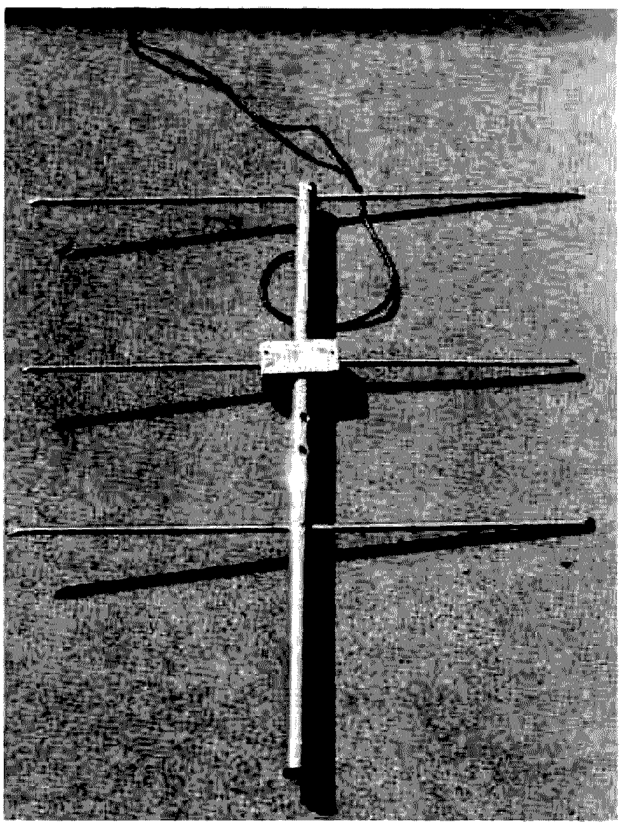
Build This Simple 220 Yagi

—3 elements, 6 dB

The $5 AJA special.



The completed 220-MHz beam.

If you're looking for an expensive, double-figure-dB gain HF antenna, try another article, because this construction project won't help you at all—especially if you want an HF skyhook. However, if the idea of a $5.00, 3-element yagi with about 6 dB of gain for 220 MHz suits you, then read on.

When the June, 1978, issue of *220 Notes* (volume 1, number 4) arrived at my doorstep, I was new to 220 MHz; in fact, the ink on my Tech ticket was still moist! So the blurb titled "Your Own Little 220 Beam" on page one captured my immediate interest. Although *220 Notes* included a marvelous sketch of the antenna (which they adapted from C. N. Zornes W9TAL), the newsletter contained no instructions for assembly. Fig. 1 is redrawn from *220 Notes* and shows antenna dimensions.

To build W9TAL's beam, I purchased a GEC-52 conical TV antenna, made by RMS Electronics, 50 Austin Place, Bronx NY 10462, for five bucks from a local radio-electronics store. I chose this model because of the cheap price, but any television antenna will do. Another route is to buy a boom and 1/8" or 3/8" aluminum rods separately.

Step 1: After taking the TV antenna from the shipping carton, remove the elements (secured to plastic hubs with pop rivets) by drilling out the rivets with a bit slightly larger than the head. Now you have several aluminum elements of various lengths and a boom.

Step 2: Measure the length of your boom. It must be at least 30 inches. The mast-cum-boom supplied with the GEC-52 is 31½ inches long. If your boom exceeds three feet, I recommend shortening it

to 30 inches. A hacksaw or saber saw will do the job. Now mark a ¾-inch point in from either end; mark another ¾-inch point on the other side, i.e., directly behind it. You will be drilling through these points, so make sure they line up! Make similar marks 19½ inches in front of the first two. Measure the diameter of your elements, add 1/16 of an inch, and drill holes in each of the four marks. The drill bit will not slip if you first punch holes in the boom with a large nail.

Step 3: Make marks midway between the holes you drilled for the reflector element. These are perpendicular to and ¼ diameter away from the original holes. Stove bolts will drop through these points to secure the reflector. Repeat this procedure for the director. Once the spots are marked, drive a large nail through them and wiggle it around to ream out the aperture.

Step 4: Time to cut your elements. Measure and cut one element 27-1/8 inches long—this is the reflector. Measure and cut another 24-1/8 inches long—this is the director. Measure and cut two elements each 12 inches long—these are the driven elements.

Step 5: Crimp the open ends of the reflector and director and one open end of each driven element with pliers to prevent water from entering and rusting them. If the crimped ends are rough, a file or sandpaper will smooth them off. Locate the midpoint of each element (13-9/16 inches for the reflector; 12-1/16 inches for the director) and punch a hole, using the nail from Step 3, to allow a bolt to pass through it.

Step 6: Take a 4-inch piece of 2" x 4" and bore a hole in it as shown in Fig. 2, to accommodate the boom. Use a smaller bore (or large bit) to drill holes in the sides of the 2" x 4". These holes should be ¾ of an inch to 1 inch deep and under no circumstance should they intersect with the boom bore.

Set a driven element in each of the two side holes (make sure it is snug against the back) and screw a 1½-inch wood screw into the top of the 2" x 4" about ½" from the edge. The screw will secure the element and will later serve as a conductor between the coax and element. Slide the 2" x 4" on the boom so that the elements' centers are 10½ inches from the middle of the reflectors' holes.

Step 7: You're in the home stretch . . . final assembly begins here. Place the reflector (remember that's the longer element) in the large holes near the rear of the boom. Align the holes in the boom and reflector so that they match. Set a flat washer over the topside hole and drop in a bolt. Tighten the bolt with a lock washer and nut on the underbelly. Repeat this for the director.

Strip 1½ inches of the coax's outer covering off the end. Twist the shielding braid into a "wire" and remove the plastic insulator from around the center conductor. The total distance between the split in the coax to the end of each driven element is 12½ inches. Measure the length from one screw in the 2" x 4" to the tip of the corresponding driven element. Subtract this size from 12½ inches and wrap all but the difference of the twisted coaxial braid around the head of the wood screw. Drive the screw as deeply as possible into the 2" x 4". Repeat this part of Step 7 for the remaining screw and the cable's center conductor.

I wrapped silver duct tape around the 2" x 4" to isolate it from the nasty Michigan winters and to increase the beam's life.

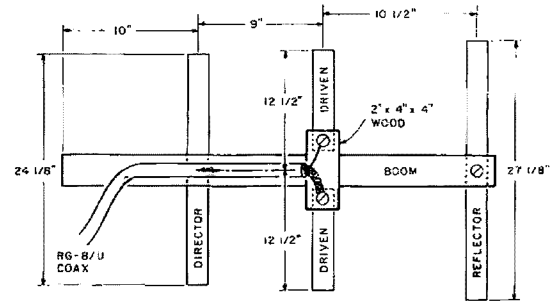


Fig. 1. Antenna and dimensions. Adapted from: 220 Notes, *volume 1, number 4, June, 1978, page 1.*

Bathtub caulking is another solution.

Results

In preliminary tests the yagi performed admirably. My first simplex contact was with Tom WB8GVC in Detroit (a distance of about fifteen miles), and the antenna was only ten feet above ground level. When I taped the beam on a twenty-foot makeshift mast (and had my father and Tom WD8OTN take turns playing rotor), I raised the WR8AOK repeater in Livonia, Michigan. WR8AOK sits forty-five miles from my home QTH—not bad for a ten-Watt Midland 13-509 rig and a twenty-five-foot run of RG-58/U. In the low power position (one Watt), I full-quieted the WR8AEF machine in Mt. Clemens, Michigan, a six-mile haul. All in all, I've been impressed with the results of W9TAL's design.

For maximum results, mount the beam as high up as possible—or, at least above surrounding trees—away from other metallic objects, and use RG-8/U coaxial cable to minimize transmission line loss.

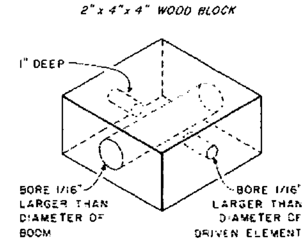

Fig. 2. Sketch of wood block holding driven elements.

I purposely neglected VHF/UHF antenna theory in this article. If you're curious about why it works, then consult one of these fine books: *VHF Antenna Handbook* from *73 Magazine* for $4.95 or *The Radio Amateur's VHF Manual* from the ARRL for $4.00. I felt the underlying theory was too much to tackle here and many hams, like myself, are more concerned with putting out a good signal. Any comments, questions, or objections you have on this fine, 6-dB, 220-MHz antenna at the minimal cost of five bucks will be answered, provided, of course, that you enclose an SASE.

As for me, I'm heading back to the radio . . . "QRZ rare DX from N8AJA in Roseville, Michigan." ■

Parts List

TV antenna (GEC-52) *or* 6½' of 1/8" or 3/8" aluminum rods and 30" boom
4" piece of 2" x 4" wood
saber saw or hacksaw with blade
2 wood screws (1" long)
2 stove bolts (1½" long) and lock and flat washers
wood bore and drill bits
electric drill
RG-8/U coax with 1 PL-259
rosin core solder and soldering iron

Denville NJ 07834

Beware of the Dreaded Phantom Ground

—exorcise those antenna gremlins

Avoiding the non-radiant antenna.

The article by John Cranston WB2DYU/2 in the March, '78, issue of *73* ("I Need A Contact!") brought back many unpleasant memories of past station operation and more than too many of how it works now. I, too, have a long history of inventing the non-radiant antenna. However, a few of the rules of thumb (or burned fingers, if you will) arrived at may be of help to other hams starting out.

If you don't read too much theory, it is harder to build an antenna that will not work than to build one that works.

From the description of what Cranston has, there seem to be a few old friends. One of my favorites is the phantom ground. All the books say that you should ground the equipment, particularly the transmitter, to avoid all sorts of troubles. Usually this leads to all sorts of troubles just like the ones you wanted to avoid, like TVI and rf burns when you touched the rig.

So what happened? Well, the ground was always shown in a picture-book station. There was all that beautiful gear, all hooked up together with a heavy copper braid ground bus to a conveniently located ground. It is the "conveniently located" that kills you. When they say ground, they mean ground, as in nice wet earth. To work, the direct earth connection must be quite close to your equipment and connected with a solid hunk of metal.

Many hams have some heavy copper water pipe that goes right through the basement shack and into the ground. Now that is a reasonable ground. If you don't have that, you don't have a ground. The further away from that you are, the less ground you have.

If your shack is on the first floor, or more probably the second floor or attic, you don't have any ground at all. What you do have is a hunk of far too thin wire draped all through the house to a water pipe and maybe a long run of that to the ground. For rf purposes, you aren't even connected to the ground. What your transmitter sees is what looks like another hunk of antenna. That, added to your nominal antenna, results in almost as good a radiator as your store-bought dummy load.

I have tried a number of different configurations of this basic circuit and can recommend it for tune-up purposes. It also is very impressive to show visitors how you can light a small neon bulb with your nose when you key the rig.

Let's get back to practical for a bit. There is no such thing as a long ground unless you can run something the diameter of a sewer pipe from the rig to the ground. I don't think that will work well, either.

So, forget the ground. Build an antenna that will work without the ground. This is not as hard as it sounds. Without the false ground to give trouble, many antennas will do the job without trouble.

Most rigs are coax-fed these days, so the basics will be for that type of output. The coax-fed antennas, dipole, beam, quad, etc., will work fine without the earth ground. Here you may want a balun or other matching device to go from unbalanced line to balanced, but it should not be critical.

If you can do it, the attic shack is the ideal location for the roof-mounted antenna. A simple mast with a small beam or quad will do nicely. From there it will be a short coax run to the rig.

So far, so good. What about that dipole you wanted to have? It doesn't matter that the rig is in the attic, but it usually happens that when you have met the condition that your rig is nowhere near a good ground, it probably is situated where you can't have a good antenna. Somehow the landscape has been carefully arranged so that there is no possibility of stringing a dipole, inverted V, or

anything resembling the antennas shown in the book.

Now what? This is where the all-time easy antenna comes into its own—the classic random-length antenna. What this is is a long piece of wire. You make it as long and as high as you can. Nominally, you want it more than ¼ wavelength long. It would be nice if it was in a straight line, but it is quite accommodating to being bent into odd shapes. It would like to be free and clear of other objects, particularly metal ones.

With a little thought, it is almost impossible to not be able to meet the requirements of this antenna, but there are a few little hitches.

It runs from your transmitter to where it ends. That means there will be radiation in the shack; however, this should not be what is usually thought of as rf in the shack, i.e., burned fingers when you touch the rig. It just has to be hooked up right. Most rigs have a 50-Ohm output. The random is high impedance. You have to use an antenna tuner. This can be as simple as a coax jack, a variable capacitor (with insulated shaft), a coil and a few clip leads, or a fancy store-bought tuner. A short run of coax from the rig to the tuner and the antenna goes from there to the great outdoors. It works quite well.

It's hard to miss, but you're not home free yet. The books still say to ground everything together. This is how you get all that rf in the shack, plus assorted rf burns and minor jolts.

You still will have your phantom ground problem. It wasn't until I got rid of both the ground and connecting the various chassis together that my setup got tamed.

Don't connect anything to anything else that you don't have to. They fight with each other. This will leave you with only one problem.

There may be potential differences between the various chassis. If you are holding onto one and reach for another, you may get bitten. This is not pleasant, so learn not to do that any more. Don't grab two pieces of gear when both are live (or plugged in). This is a small price to pay for a reliable attic system. It may not happen that your particular gear does that. Some of mine does and some doesn't.

Of course, you are going to ground your antenna when not in use . . . or are you? You will have the same problem trying to ground your antenna to a phantom ground as your transmitter had working with it.

Antenna grounding is supposed to serve two purposes. It is fondly believed that it will protect your rig from a direct lightning hit.

Lots of luck. Even with the usual textbook ham ground setup, that is asking a lot. A direct lightning hit will go to ground, but it is probably going to take everything along the path with it. I don't know if the usual antenna, lead-in, and grounding setup is going to stay put for that, not to mention any gear connected to it. The best you usually hope for, and the usual case, is protection against the static charge buildup from a nearby electrical storm. While this is not usually big enough to turn your antenna into abstract artwork, it is often big enough to put a walloping charge into the front end of any rig that's there.

Here the solution is simple. It is not so much a direct earth ground you need as a chassis ground connection. Any of the antenna switching arrangements can usually be hooked up to short the antenna lead directly to the ground of the coax connector (chassis ground).

I haven't seen it mentioned in years, but there was a time when many schematics made a distinction between chassis ground and earth ground. There are different schematic symbols for each. The familiar ground symbol, Fig. 1(a), is the one for chassis ground. Fig. 1(b) is the symbol for earth ground.

If your shack location is such that you can't get a good earth ground for antenna grounding, the chassis ground will still work a lot better than leaving your rig there to get hit.

It also doesn't cost much to run a ground wire to your shack and try it for rf purposes. Then if you have trouble with operating, remove it when you use your rig and reconnect it just for

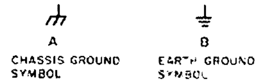

Fig. 1. Schematic ground symbols.

electrical safety when you are not operating.

The key is to go by the book as far as you can and only make such modifications as you have to for your particular circumstances. Then do as much as you can to restore non-operating safety.

I hope these two particular techniques, the use of a tuned random-length antenna and the avoidance of a phantom ground, will help solve a few problems for those who are just beginning or not able to use a more conventional configuration.

It drove me nuts for quite some time until I got the hang of it. It's not the best, but it will be reliable when properly applied. ■

A Close Encounter With Voyager I

—the W6VIO story

Voyager II is next.

Dr. Norman L. Chalfin K6PGX
JPL Amateur Radio Club
4800 Oak Grove Dr.
Pasadena CA 91103

Jet Propulsion Laboratory Amateur Radio Club members gave up lunch periods, many after-work hours, and weekends during the period from March 1-11, 1979, to operate their club station W6VIO in celebration of the close approach of the *Voyager I* space probe to the planet Jupiter and its four Galilean satellites, Io, Europa, Ganymede, and Callisto.

Dick Piety K6SVP at the SSTV position. The image on the screen is of Callisto, one of Jupiter's moons.

Dick Piety K6SVP organized and managed the operation. He was assisted by Jim Lumsden WA6MYJ. Jim mounted a Herculean effort in getting the newly refurbished trailer which constitutes the W6VIO shack ready for the event. Equipment, stored in many locations during the refurbishing, had to be returned to the shack and reinstalled in the beautifully arranged shelves and decks.

The 1540 contacts made in the various bands on which the operation was mounted include:

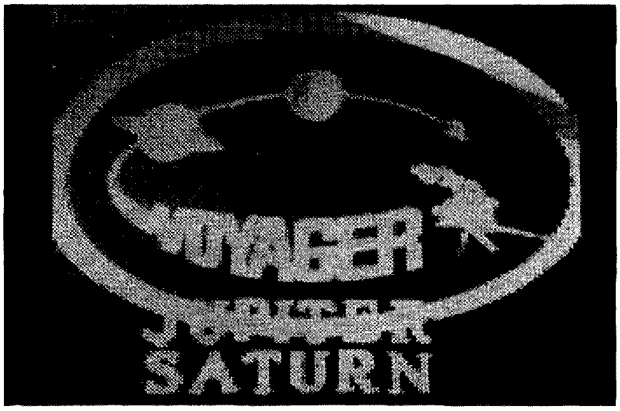
10m	phone	281

(includes a number of SSTV contacts)

10m	CW	21
15m	phone	123
15m	CW	164
20m	phone	362

(includes many SSTV contacts)

20m	CW	157
40m	CW	10
75m	phone	1



One of the SSTV monitor views of the W6VIO ID during the Voyager I *commemorative.*

A slow-scan image of the great red spot on Jupiter.

2m	FM	348

(includes check-ins to various JPL/Goldstone* nets run during the commemorative)

220 MHz	FM	72
OSCAR		1

There were 79 contacts outside the United States.

Interesting sidelights arose during the commemorative. Dick says he "doesn't believe" the contact on 2 meters who gave a K7 call and said he was speaking from Seattle. (Seattle to Pasadena on 2m?) Merv MacMedan N6NO began a CW contact with a Spanish amateur who wouldn't let him go on to others. Merv explained to him in Spanish about the *Voyager* commemorative. The Spanish amateur wanted to "rag-chew." Jim made a contact on SSTV with a Wichita Falls, Texas, amateur who said he was recording the pictures for his high school class of fourteen-year-olds. Dave Ingram K4TWJ telegraphed that he was recording the Jupiter images and sending them to the local press as fast as he received them. A Denver amateur contacted the Denver *Post*. They called K6SVP on the phone to interview him about the operation. A contact with F6KCP by W6VIO led to five or six other French amateurs joining the activity.

The promised QSL card, including Jupiter pictures made by *Voyager I's* cameras, was a magnet to pull in the contacts. All who contacted W6VIO during the March 1-11, 1979, period will receive QSLs if they send an SASE to W6VIO or QSL through their bureaus. The card also identifies the major discoveries about Jupiter and its moons made by the *Voyager I* spacecraft in its close encounter of the most spectacular kind. Those who remember the *Viking* commemorative card from N6V, operated by the JPL club during the landings on Mars, can appreciate the beauty of these very special QSLs.

From July 6-15, 1979, there will be a second Jupiter fly-by commemorative for the *Voyager II* Mission. It will have a somewhat different card. If you missed out on *Voyager I*, try for *Voyager II*.

The individual members of the JPL ARC (in addition to myself) who took part in the *Voyager I* commemorative are: Dick Piety K6SVP (chairman of the commemorative operation), John Repar WA6LWD, Stan Sander N6MP, Ron Zenone W6TUZ, Warren Apel K6GPK, Merv MacMedan N6NO, Jim Longthorne WA6KPW (off-lab member), Bob Gosline AE6S, Rich Soikkele WD6ERI (an Arcadia, California, high school student, 16 years old, who is communications associate on the Sunfire I project), George Morris W6ABW, Jim Lumsden WA6MYJ (facilities chairman for W6VIO), Mike Griffin N6WU (president of the JPL ARC), and Glenn Berry K6GHJ (who organized the reconstruction of the trailer).■

*The JPL Amateur Radio Club (operating on 220 with WR6APS at La Canada CA) and its affiliated Goldstone Club (operating on 220 with WR6AZN from Table Mountain, near Wrightwood CA), are linked together for a general amateur radio news net on each Tuesday at 8:00 pm PST and for an AMSAT/OSCAR news net on each Wednesday at 8:00 pm PST. The combined net covers all of southern California.

GIANT Wire Antennas

—impress the neighbors

Have you ever found yourself wanting an antenna that was easy to put up, had gain over a dipole, was simple to match, and could work on more than one band? Then read on. This article shows how to design and build wire antennas which are longer than a half wavelength. These antennas may be operated as dipoles or V-beams. By careful choice of leg length, it is possible to build an antenna which will work on several amateur bands, but requires only a single feedline. The input impedance is about 200 Ohms and may easily be matched to 50-Ohm coax with a 4:1 balun.

Background

One advantage of the half-wave dipole is its low feedpoint impedance. The reason for this is shown in the upper drawing of Fig. 1. This drawing shows the standing waves of voltage and current which are present on a resonant antenna. From Ohm's Law, the input impedance is equal to the voltage divided by the current at the feedpoint of the antenna. For a half-wave dipole, the voltage at the feedpoint is low and the current is high, which gives a low value of impedance —typically, 50 to 70 Ohms.

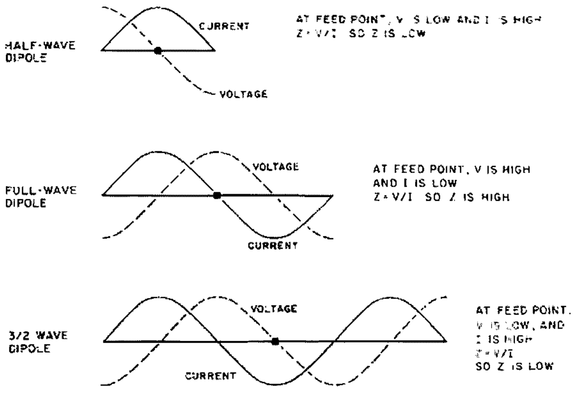

Fig. 1. Antenna impedance is determined by voltage and current at the feedpoint.

Many hams use half-wave antennas, but it is also possible to make a dipole in which each leg is much longer than a quarter wavelength. Fig. 1 also shows the voltage and current distributions for 1-wavelength and 3/2-wavelength dipoles. Notice that the current in the center of a full-wave antenna is low and the voltage is high, resulting in a very high input impedance on the order of several thousand Ohms. However, the 3/2-wavelength antenna has a voltage minimum at its center, similar to the half-wavelength dipole. The feedpoint impedance is again relatively low—around 100 Ohms or so.

At the ends of each dipole drawn in Fig. 1, the current is shown to be at a minimum value and the voltage is maximum. This makes good sense if you think about it. The current flowing at the end of a piece of wire must be zero because it has nowhere to go. On the other hand, the voltage at the end of a wire easily can be quite high. The important point to remember is that to get a low value of input impedance, there must be a voltage minimum at the center of the antenna. In other words, each leg of the antenna must be an odd number of quarter wavelengths. For the half-wave dipole, each leg is ¼ of a wavelength, while for the 3/2-wavelength dipole, each leg is ¾ of a wavelength. Each of these antennas has a voltage minimum at its center, and each also has a low value of input impedance.

Determining the Correct Antenna Length

Table 1 shows the formulas to use in order to calculate the right length for each leg of the antenna at the frequency of interest, once you have chosen how many quarter wavelengths you want each leg to be. Notice that a ¾-wavelength leg is *more* than 3 times as long as a ¼-wavelength leg. This is because the influence of "end effect" diminishes as the number of quarter wavelengths in each leg increases.

The antenna may also be oriented as a V-beam rather than a dipole, if directivity is desired. Table 2 shows the included angle (angle between the two legs of the V) for several different V-beam leg lengths, as well as the approximate gain of each configuration.

For those of you with lots of real estate, Table 3 gives the data required to design and build antennas which are truly giants. The feedpoint impedance of these monsters is in the neighborhood of the 200-Ohm value given for the antennas of Table 1.

Leg Length in Wavelengths	Leg Length in Feet (f in MHz)
1/4	234/f
3/4	738/f
5/4	1230/f
7/4	1722/f
9/4	2214/f
11/4	2706/f
13/4	3198/f
15/4	3690/f
17/4	4182/f
19/4	4674/f
21/4	5166/f
23/4	5658/f
25/4	6150/f
27/4	6642/f
29/4	7134/f
31/4	7626/f
33/4	8118/f
35/4	8610/f
37/4	9102/f
39/4	9594/f
41/4	10086/f
43/4	10578/f

Table 1. Determining the correct leg length.

The formulas shown in these tables will give leg lengths which are approximately correct, but these values should be used only as starting points. All antennas should be cut a little bit long to allow for trimming to the exact length which is required. The actual resonant frequency of any antenna is affected by factors such as height above the earth and proximity to other objects.

Multiband Use

Certain leg lengths will resonate on more than one amateur band, which can be very convenient. I used to work in a small coal-mining town deep in the hills and hollows of southern West Virginia. I lived in a mobile home and had 340 feet of RG-8 coax which ran from my ham shack up the hollow to a hilltop behind my trailer. I badly needed an antenna which could cover several bands with a single feedline and which had some gain to make up for the cable losses.

While reading Ed Noll's book, *73 Dipole and Long-Wire Antennas*, I came across the information given here as Table 1. Ed explained that multiband operation was possible, so I got out my calculator and made a list of antenna lengths which would be resonant in the bands I wanted to operate (80 and 20 meters). Then I looked through my list to see if any of the numbers matched. It turned out that a ¾-wavelength leg on 80 meters was the same size as a 11/4-wavelength leg on 20 meters—about 190 feet in length.

This antenna was built from #12 copperweld wire and fed through a W2AU balun with a 4:1 impedance ratio. The swr was below 2:1 across the whole 20 meter band. On 80 meters, the resonant frequency was lower than I had planned (3.7 MHz versus 3.9 MHz), but I still was able to operate my Triton II on 75 meter phone with the swr around 3:1.

Other suitable combinations can be found by plugging desired frequencies of operation into the various equations and making a list of the resulting leg lengths. For example, a leg length of about 440 feet should resonate on both 80 and and 40 meters, while 428 feet looks good for 20 and 15 meters. It has been my experience that the actual leg lengths on 80 meters are somewhat shorter than the formula values, so a leg length of 428 feet may work well on all bands from 80 to 15 meters. A leg length of 362 feet should work on 40 and 20 meters, 330 feet on 10 and 15 meters, and 310 feet on 80 and 15 meters. For really big antennas, a leg length of 710 feet looks good on 40, 20, and 15 meters, 943 feet for 160 and 80 meters, and 673 feet for 160 and 20 meters.

Leg Length in Wavelengths	Included Angle in Degrees	Gain in dB
11/4	60	5.3
13/4	56	5.8
15/4	52	6.3
17/4	48	6.8
19/4	46	7.2
21/4	44	7.6
23/4	42	8.0
25/4	40	8.4
27/4	38	8.8
29/4	37	9.2
31/4	36	9.6
33/4	35	10.0
35/4	34	10.3
37/4	33	10.5
39/4	32	10.7
41/4	31	10.9

Table 2. Gain and included angle for V-beams.

Conclusion

This article has described large centerfed antennas where the length of each leg is an odd number of quarter wavelengths. Multiband use of a single antenna is possible by a judicious choice of leg length, and low-standing wave ratios are achieved by placing a 4:1 balun at the feedpoint. These large antennas show gain over a normal dipole and may be oriented in either straight-line or V-beam configuration. ■

Corrections

It has been called to our attention that the breadboard shown on page 51 of our June, 1979, issue is indeed Continental Specialties Corporation's Model EXP-300 Experimentor Proto-Board®.

John C. Burnett
Managing Editor

In my article "Build the \$80 Wonder" (November, 1978), there was an error in the input amplifier shown in Fig. 6. The corrected portion is shown below.

Howard M. Berlin W3HB
Newark DE

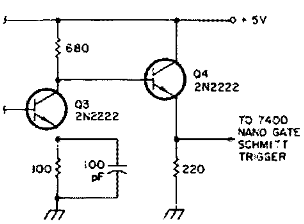

Fig. 6 (partial), "Build the \$80 Wonder."

In my article "12 Volts, 5 Amps, 3 Terminals" (April, 1979), there was an error in the schematic—the electrolytic cap should be somewhere in the range of 2500-4000 uF at 30 volts or so, not 500 uF at 1000 volts. My power supply has two 100-uF, 35-volt caps in parallel, but it should be emphasized that this was a commercially-built supply (minus the regulator which is what the article was intended to introduce). The designer of the supply took a shortcut in the cap's value in order to retain the small size of the supply. I am recommending the 2500-4000 uF, 35-volt electrolytics to those who have been writing, if they can get along with the extra space that is required.

Again, the intended purpose of the article was to introduce a very effective way to obtain regulation of a power supply with a minimum of external parts (one!). If anyone was to duplicate the circuit shown, it does work, and will make an effective supply at a small cost as long as the cap's value is changed as noted here. Any "computer-grade" electrolytic with a rating of 30 volts or more—and many are advertised at bargain prices in *73*—should work just fine.

Readers might also be interested in knowing that one supplier of the chip, Tri-Tek, has just dropped their price for the 78H12 to \$6.50. Fairchild has also introduced several other new regulator chips that might prove of value.

Miami FL

Ham Help

I am looking for a schematic of a device which would allow me to tune in a CW signal and have the received Morse characters translated into Baudot and ASCII. Once translated, the signal could produce a teletype™ copy of the CW being received.

There did exist the Converter Shift Register Group AN/UGA-3A (designed and built in the 1960s) which translated CW to Baudot. This unit used discrete components and weighed some 110 lbs. Its CW speed capability range was 10-110 wpm, machine-sent. Two-level Morse-keyed dc, or Morse-keyed audio signal inputs were accepted and translated to 5-level Baudot, and then to TTY copy.

I would appreciate hearing from anyone who may have an arrangement such as this. Thank you.

Microcomputer RTTY . . . a Software TU

—use your 8080 and very little else

Count frequencies, too.

Albert S. Woodhull N1AW
Enfield Road, RFD 2
Pelham MA 01002

Microprocessors are not just super calculators. They are general-purpose electronic circuits waiting only for programs to transform them into specialized devices. In this article I will describe how a computer can be used as a frequency counter, and I will show how the counting program can become the basis of a microprocessor-centered RTTY terminal unit. I am writing this also to show how easy it can be to replace hardware with software. Applications such as the one I will describe require only a fraction of the amount of memory that is needed to do calculations with a high-level language such as BASIC. And, for the experimenter, replacing gadgets with programs has another great advantage. No longer do you need to worry about the condition of your gear if a lengthy equipment modification doesn't work. Rewind your tape cassette and you can have the old version up and running in a few seconds.

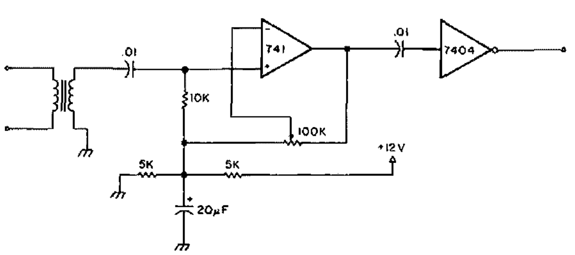

Fig. 1. Input interface. The pot is used to adjust the gain of the 741 amplifier until it drives the 7404 TTL inverter to the point of producing a clean square wave output of the same frequency as the input. 60- or 120-cycle hum is the villain that can make this difficult; the transformer may not always be necessary, but sometimes eliminating the common ground connection gets rid of hum.

Counting Frequencies With a Computer

The computer works with ones and zeros; counting is a very simple task for it. A little bit of external hardware help is needed, however, to get the signal from the outside world into the form the computer requires. Fig. 1 shows an adequate arrangement. An operational amplifier circuit boosts the input signal to a level adequate to drive a TTL inverter. The resulting square wave is applied to one bit of an input port of the computer. On most systems, the other seven bits can just be left floating, but, if you are picky, you can tie them to either ground or +5 volts. On my home-brew computer, I have a number of input and output ports that are implemented as single bits for applications like this. The transformer shown may not be necessary, but may help in keeping 60-cycle interference out of the system.

The easiest way to measure audio frequencies is to time the duration of a half cycle. Fig. 2 shows a flowchart, and Fig. 3 shows an 8080A program to do this. Two registers are used, one to hold the previous input, and one to count up the number of times the program loops between changes in the input. Suppose, at the starting time, the input signal from the inverter is in the 0 phase of the square wave. The unused seven bits will be read as ones, and 11111110 will be stored. Until the input changes to the 1 phase, the program will loop and the counter will count. Eventually, a time will come when the input is read as 11111111. When this happens, the count will be displayed and a new count started. If desired, a bit of programming could be done to calculate the frequency in decimal units from the binary representation of the duration of a half cycle, but, for many purposes, it is adequate to know what pattern on the LED display corresponds to a desired frequency.

For a typical 8080A system with a 500-ns clock, the instruction loop just

discussed will require 14.5 µsec. If you were trying to measure the tones from an AFSK generator, this counter would produce a count of 16 (00010000 in binary) for a 2125-Hz input or a count of 15 (00001111) for a 2295-Hz input. That might be good for some purposes, but it obviously is not very accurate. The way to make a timer more accurate is to time longer intervals. The counting time can be doubled by timing whole cycles of the input instead of half cycles. This also will eliminate inaccuracy due to asymmetry in the square wave input. For the 8080A program illustrated, this can be accomplished by changing the JZ (jump on zero) instruction to JNC (jump on no carry). Following a comparison operation, the zero flag is set when the numbers compared are equal, so in the original version of the program, the loop is broken whenever the input changes from 1 to 0 or from 0 to 1. The carry flag is set when the number in the accumulator register is less than the comparison number. Thus, by using the no-carry condition to stay in the loop, the timer ignores transitions from 0 to 1 and the count accumulates until a transition from 1 to 0 occurs.

A second way to increase accuracy is to put the basic program inside a larger loop that counts down a predetermined number of cycles of the input signal. Figs. 4 and 5 show the flowchart and program for this approach. The inner loop again takes 14.5 µsec, but now the JNC instruction is used to keep the timer going for the entire duration of an audio cycle. The outer loop causes the inner loop to be repeated as many times as the value initially loaded into register D calls for. With this approach, standard AFSK tones in the range of 2000 to 3000 Hz can be measured to the nearest 10 Hz or so. This will suffice for adjusting an AFSK generator or calibrating an oscillator to be used in adjusting a RTTY demodulator. More accuracy yet can be achieved by timing a larger number of cycles and accumulating the count in a 16-bit register pair. Still other software frills could turn the computer into a fancy frequency meter indeed, but that is not my present goal. Instead, I would like to show how the basic timing program can be used to build a radioteletype terminal unit with capabilities not usually found in the simpler analog TU circuits.

The Software Terminal Unit

My home-brew computer decodes audio signals from an audio cassette recorder by means of a simple cycle timer program which is stored in read-only memory. Compared to the problems of decoding over-the-air RTTY signals, it is trivial to decode a tape. A few preliminary experiments showed me that the simple frequency measuring routines could work on clear and strong signals, so I set out to define the additional requirements for RTTY.

Essential features for RTTY are some kind of filtering to minimize the effects of interferences and some kind of tuning indicator. Another feature, not necessary, but very desirable, is a squelch or mark-hold provision to keep the printer from running wild when a useful signal is not present. Finally, an easy way of throwing in a locally-generated line feed or carriage return can sometimes prevent loss of print. Doing all this in software is easy.

The flowchart of Fig. 6 shows how all these provisions are included. Entry and exit from the program are through a control section which allows a local ASCII keyboard to direct operations. Next, a cycle timer section determines the frequency of the incoming audio. Decision routines cause execution to branch, first to display the current state on a tuning indicator, and then to take appropriate action. A "noise counter" disables the printer whenever the signal-to-noise ratio becomes lower than the preprogrammed acceptable limit. A "signal counter" takes over the functions of a post-detection low-pass filter, and the processed data then drives the printer magnet through an output port and very simple interface circuitry.

The details can be seen in the program listing. In my system, a surplus 8-bit parallel-output ASCII keyboard has its data lines connected to one input port and its strobe line connected to another. The control section of the program first examines the strobe signal and skips to the frequency-measurement section if no key is depressed. If a key is pressed, a subroutine in my monitor program is called which converts the ASCII to Baudot and drives the printer. The subroutine checks for control characters and returns immediately when one is encountered. The TU program then checks for ↑B (control B) or ↑E characters, which cause exits to either a RTTY transmit routine or the control level of my monitor program. ↑T, ↑N, or ↑R characters are stored for later reference; they signify Tune (no printing), Normal (low tone is mark), and Reverse (high tone is mark).

The frequency measurement portion of the pro-

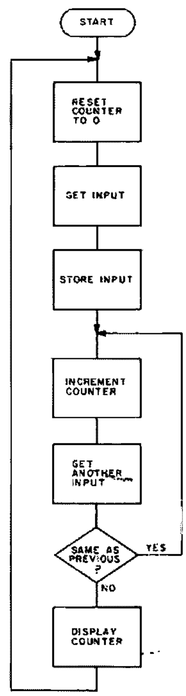

Fig. 2. Flowchart for frequency measurement by cycle timing. Note that this simple version times the duration of a half cycle of input.

```
START   MVI C 00      reset counter
        IN AUDIO      get input
        MOV B,A       store it
LOOP    INR C         increment counter
        IN AUDIO      get new input
        CMP B         compare with first input
        JZ LOOP       If same repeat cycle
        MOV A,C       otherwise display count
        OUT DISPLAY
        JMP START     and do it all again
```

Fig. 3. An 8080 program that times half cycles of audio according to the flowchart of Fig. 2. The DISPLAY output port can be a row of LEDs or 7-segment displays which show the count in octal or hexadecimal. The meaning of the count in real-time units will depend on the clock frequency of the processor.

gram works like the routines described in the first part of this article, with two refinements. It doesn't matter that a simple continuously-cycling routine gives a short count on its first cycle. For RTTY decoding, an accurate count is needed the first

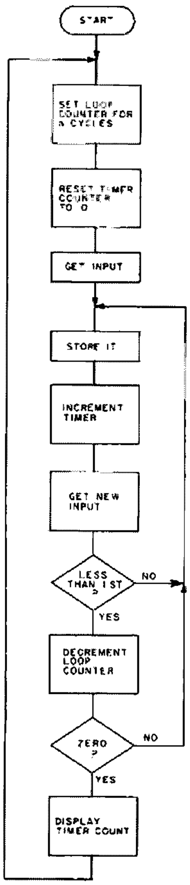

Fig. 4. Flowchart for an accurate frequency-measurement program that times the duration of n whole cycles of the input signal.

time. This problem is solved by an extra loop which causes the computer to wait for the cycle in progress to finish before the following five cycles of audio are timed. The other refinement is a more complicated nesting of the inner and outer loops which keeps the execution time constant regardless of which branch is followed. This is aided by inserting a "nonsense instruction" (MOV B,B) into one branch to compensate for the execution time of the DCR C instruction in the other branch.

All the information needed to accurately tune in a RTTY station and drive the printer is in the output of the frequency measurement section of the program. With analog circuitry, at this point one would use a comparator to decide whether a voltage was above or below a criterion level. Having a count, not a voltage, and having the power of the microprocessor makes possible a six-way decision. Try setting up comparators to do that at the output of a phase-locked loop! I use the various possible outcomes of this six-way decision to light up a row of LEDs on the front panel of my computer. As the receiver is tuned across a signal, the light appears to move from left to right as the audio tone goes from low to high. Fig. 7 illustrates the patterns

Constant	Locations In Assembled Listing
CRIT1	044A
CRIT2	044F
CRIT3	0454
CRIT4	0459
CRIT5	045E
KBDSTB	0401
KBD	0408
KBDW	04E1
PRINT	040A 04E8
MONITOR	0429
AUDIO	0430 0433 043A
PRINTER	0479 04CE 04DC
LEDDISP	0468 0480 0487 0499 04A0

Table 1. The above locations will probably have to be changed to make the TU program run on a different machine. The values for CRIT1, CRIT2, CRIT3, CRIT4, and CRIT5 will depend on the clock frequency of the computer being used. The other values listed are port numbers or, in the case of PRINT and MONITOR, routines in the author's ROM monitor.

observed. The effectiveness of the technique is due to the criteria for the comparisons having been chosen in such a way that a clear indication that the signal is not tuned in exactly on center is given before the error is great enough to cause inaccurate printing. With practice, it is also easy to spot shifts which are too wide, or stations transmitting "upside down."

The mark-hold and low-pass filtering techniques I use are also examples of simple software implementation of functions that would be relatively complex with analog circuits. Each of these features uses a counter. The mark-hold is controlled by the noise counter. This register is incremented when a tone too high or too low to be a valid RTTY signal is encountered. Valid signals decrement the same counter. Limits are placed on the maximum and minimum values the noise counter can hold, and, after each frequency measurement, the noise-counter value is compared with an intermediate criterion.

When the criterion is exceeded, operation of the printer is suppressed. With the values given in the listing, printing will proceed when a good signal is decoded one-third of the time. When the signal drops out, the printer is silenced almost immediately, but a fraction of a second of steady mark tone at the beginning of a transmission immediately enables the printer.

The low-pass filter also uses a counter, which I call the signal counter. Mark signals increment this counter and space signals decrement it. The counter is limited to a minimum value of zero and a maximum value of seven. A mark signal is sent to the printer when the value is four or higher; otherwise, a space signal is generated. Thus, at any time, the printer is given a signal corresponding to the majority of the eight previous samples of audio from the receiver. Without some

```
START  MVI D,n        set loop counter
       MVI C,O        reset timer counter
       IN AUDIO       get input
LOOP   MOV B,A        store it
       INR C          increment timer
       IN AUDIO       get new input
       CMP B          compare with first input
       JNC LOOP       if equal to or greater than first repeat cycle
       DCR D          otherwise decrement cycle counter
       JNZ LOOP       and continue timing another cycle
       MOV A,C        when done, retrieve the total count and show it
       OUT DISPLAY
       JMP START      and do it all again
```

Fig. 5. The 8080 program corresponding to the flowchart of Fig. 4. The count indicates the duration of n complete cycles of the audio input signal.

form of filtering of this sort, the information in 80% of the received signal is lost, since the printer itself samples only 20% of each bit.

The last part of the listing isn't really part of the RTTY receiving routine at all. This is a simple loop that enables me to use the ASCII keyboard for transmitting RTTY. It includes a test to recognize a ↑C character as a command to leave the transmit routine and return to the receive routine. It is not a misprint that the keyboard is called by a different port number here than that used in the control section of the program. I decode two different port numbers for my keyboard; the one used here initiates a WAIT state in the 8080A which is terminated by the falling edge of the keyboard strobe signal. This allows me to simplify the coding used for getting keyboard input in cases like this.

It would be cruel to present a program listing of this sort without pointing out the parts of the program that might need to be changed to make it run on another system. Table 1 lists the instructions which are unique to my own computer. For the most part, patching the program will require changing only I/O port assignments and relocating addresses, but it should be noted that a major and crucial difference between my computer and most others is the clock frequency. My junk-box crystal gives me a clock period of 694 ns instead of the usual 500 ns. The various criteria constants will need to be reevaluated to suit the timing of another system. This can be done experimentally by using a calibrated audio oscillator (calibrate it with the timer progam!) and trying different values for each criterion, using the tuning indicator to check results. For example, CRITERION3 should be a value that causes the low space and high mark lights to blink as the audio input is rocked around 2210 Hz.

Interfacing and Operation

A few pieces of hardware external to the computer are needed, of course. At the input, a circuit such as the one already described in Fig. 1 is needed to convert the receiver audio to digital levels. It will help if a bit of audio filtering precedes this. Fig. 8 shows a simple filter which gives good results when followed by the recommended 10k-Ohm load. The .05-uF capacitor should be chosen to give a peak at around 2200 Hz. The last external item

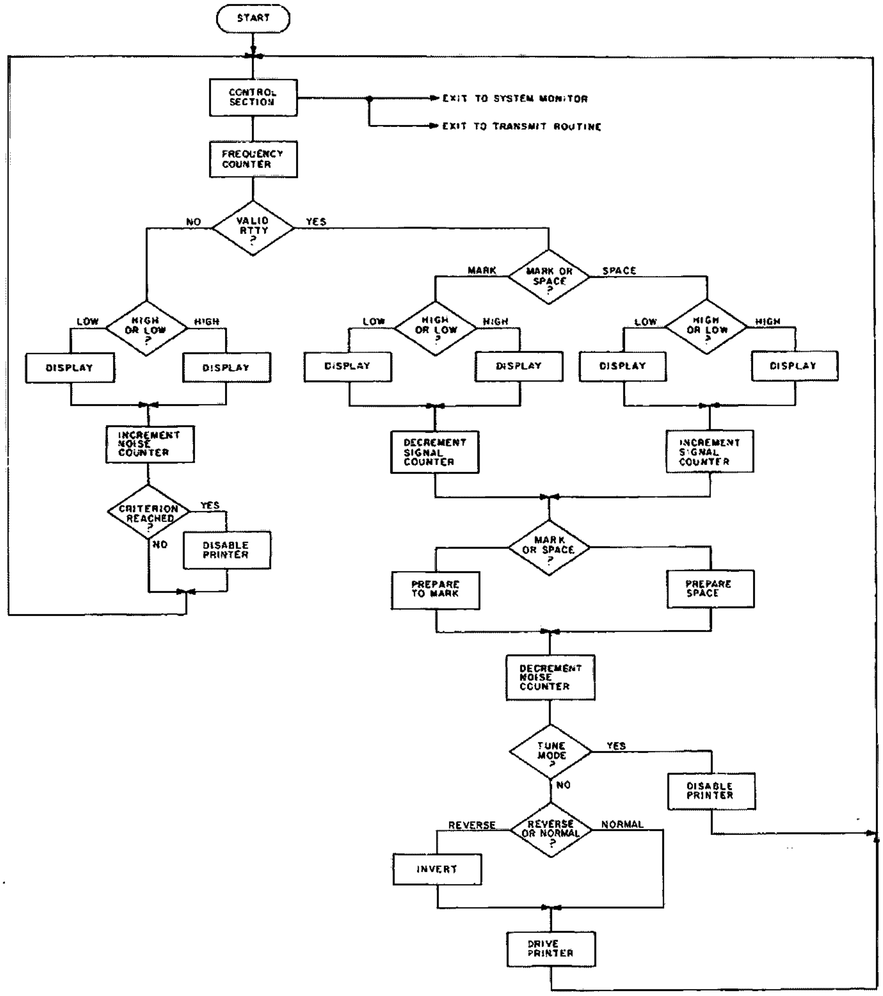

Fig. 6. Flowchart for complete TU program. Note the 6-way partition of the data for driving the tuning display. The noise counter squelches the printer when there is too much noise present. The signal counter acts as a post-detection low-pass filter.

needed is a driver for the teleprinter loop. Fig. 9 shows how I do it. A high-voltage transistor can be used for the switch if one is available. The piggyback circuit shown allows the use of relatively low-voltage "experimenter grab bag" power transistors to switch the high-voltage loop current.

For initial setup, an oscilloscope is convenient to allow determination of the proper audio level. I usually use a simple audio monitor connected right at the computer input port. With this arrangement, I can tell

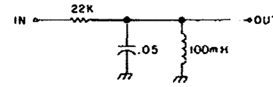

Fig. 8. A simple 2200-Hz filter. A lower-value resistor will widen the passband. Selecting capacitors from the junk box is the easiest way to tune the filter.

by ear when the audio level is adequate. Tuning is simply a matter of watching the LED display and making corrections when the low mark or high space lights begin to flash.

As I said at the start, one of the advantages of software is the ease of modification. Just sitting down to type this manuscript made me think of four or five changes, and I just had to try them before getting back to the typewriter. I'm sure anyone who tries this method of copying RTTY will come up with other changes. I intend to do some experimenting with different amounts of averaging in the signal counter and different criteria in the noise counter. It also would be possible to add more control signals to instantly modify the criteria and allow for different shifts. Enough information is extracted to allow the generation of control signals for afc. I would enjoy hearing from readers who undertake some of these improvements. ■

Fig. 7. Some of the possible combinations seen on the row of LEDs that serve as a tuning indicator. It is very easy to see which way the receiver dial should be tuned to maintain good copy. O = on; ● = off.

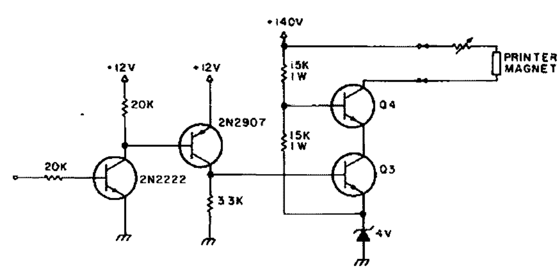

Fig. 9. A TTL-to-60-mA loop interface circuit. Q3 and Q4 could be replaced by a single high-voltage transistor. This piggyback circuit is a useful one for switching high voltages with low-voltage transistors. In my station, I use two unmarked TO-220-type power transistors from a "40 for $1.98" special pack.

Baudot Hard Copy For Your SWTPC

—noisy, but cheap

Tie a 6800 to a five-level Teletype™.

Garry Caudell K4HBG
3125 Robin Lynn Drive
Ashland KY 41101

In an earlier article (March, 1978), I discussed the use of a simple search program. In this article, I'll explain hardware and software to tie an SWTPC 6800 to a Baudot Teletype™.

Everyone probably knows the disadvantages of the old Baudot machines, such as being slow, having a limited character set, etc. However, on the plus side, they are cheap and compatible with ham radio operation. If you want cheap (but slow) hard copy, or if you want to use the CRT terminal as a glass Teletype, keep reading.

The simplest way to get hard copy is to use the standard SWTPC MP-S board. All you need to build is the clock divider (see Fig. 2). Unfortunately, this board uses an ACIA (6850) chip, and there is no way to tell it that you don't need all eleven bits when you really need only seven (five data bits plus start and stop bits). If you are willing to slow down the already slow printer, it will think that the extra bits are just long stop bits. Trying to copy this way would not work on anything that was sent at near-synchronous speed. The program would need to be changed to accommodate an ACIA (see listing 2 in Fig. 4).

The circuit I used to interface my SWTPC 6800 computer to my Model 15 Teletype is an expansion of the circuit used by Mark J. Borgerson in his article in *73* (November, 1976). It has a PIA (6820) controlling a UART (S-1883). All connections into the PIA are identical to those used by the MP-L board.

The clock for the UART is derived from the 600-baud clock divided by 13. If you are using the 1.843-MHz crystal recommended by Motorola for the MC14411 baud generator chip, this comes out slightly high. If you are using the crystal which SWTPC rec-

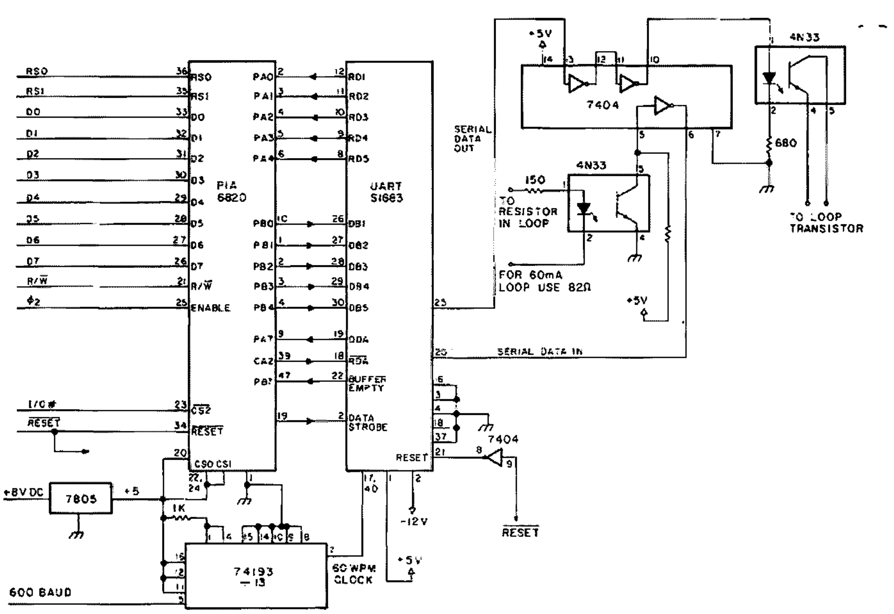

Fig. 1.

ommends, it will be slightly low. In either case, it is as close as the rest of the baud rates, if you follow SWTPC recommendations. (I don't know why SWTPC did this.) This circuit works well and gives one less variable, as compared to using a tunable oscillator (one less confusion factor when trying to get the thing working).

The A-side of the PIA ties to the receive data side of the UART, with bit 7 used for a data ready indication. CA2 is used to clear the UART.

The B-side of the PIA is used as an output to drive the UART, with bit 7 used as an input to poll the UART for a buffer empty signal. CB2 is used to strobe the UART to tell it when to transmit data.

I found it useful to connect the UART reset to the SWTPC reset (through a 7404 inverting gate). This may not be necessary, as most UART circuits do not require a reset, but simply ground this pin. I felt that if the UART did need a reset, this would be well worthwhile to include.

Data in and data out are buffered by the 7404 gates and by 4N33 optical couplers.

In my system, the output is in series with the base of my loop-keying transistor. This allows the printer to

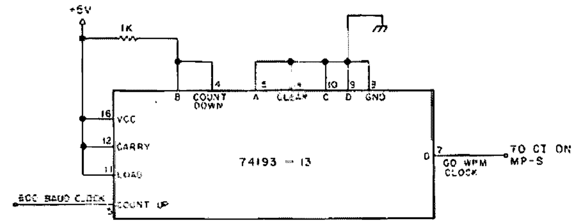

Fig. 2. Build this only if you are going to use the MP-S board. Don't jumper any baud rate on the board.

Fig. 3. Program listing 1.

operate either from my ST-5 or the computer, without doing any switching. Similarly, the input is a resistor in the loop which allows either the keyboard or the ST-5 input to the computer.

Construction

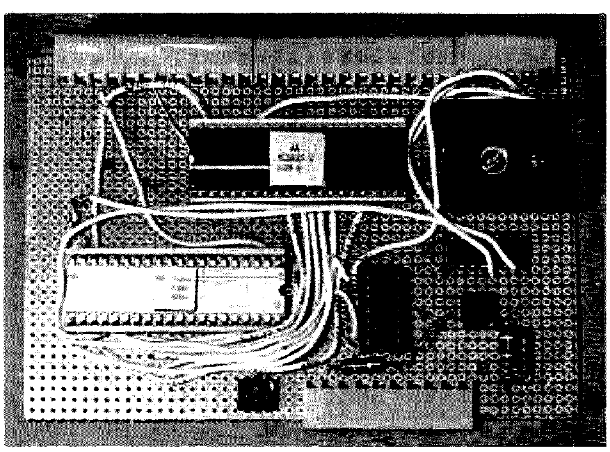
I am sorry to say that I do not have a nice printed circuit board to build this gadget on. Mine is hand-wired on a piece of vectorboard which is the same size as the SWTPC I/O boards and has the same plug arrangement. For no good reason, I put it on slot 3.

Program

The program to convert ASCII to Baudot (see listing 1) is noteworthy only because of the ease of relocating it. If you have a block-move program, only the memory locations in lines 1130, 1210, and 1220 have to be changed. From here on, relative or indexed addressing is used.

The first part of the program (1040-1110) consists of a lookup table to convert Baudot to ASCII. In the table, the conversion is accomplished by pointing the index register at the start of the table and using the ASCII character (6-bit form) as an offset. Line feed and carriage return are handled as exceptions. No other control characters are allowed (bell might have been useful).

Space is handled as an exception because some machines are set up for unshift on space. In the program, space is handled as a letters character only.



Home-brew I/O board.

The CINT (1120-1140) subroutine is used to restore the flag so that the PIA will be initiated after a reset.

OUTEEE (1150) is the point to branch to in order to output a character in "A" accumulator (just like MIKBUG). The first thing it does (lines 1150-1160) is reject any lowercase ASCII. Next, it stores the index register and points the index register to the start of the conversion table (lines 1210-1220).

In line 1230, the program makes sure that we are talking about 7-bit ASCII and then saves the "B" accumulator (line 1240).

The test in line 1260 is to see if the PIA has been initialized or not. It does this by checking to see what is stored in LAST+1 (line 1510). If it sees a negative value ($FF), it will go through the INT portion (1290-1340) which will initialize the PIA, clear the last flag, and put the printer in letters shift.

If it sees a nonnegative value, it will jump around this section. All this means that, if you have reset the computer, you need to restore the $FF in LAST+1. This is the purpose of the CINT routine.

Lines 1350-1470 check for carriage return, line feed, and space. If it finds them, it substitutes values for them so they can be printed. Line 1472 rejects all other control characters. Line 1480 converts the character to 6-bit ASCII, and then it is stored to be sent later (1490).

In 6-bit ASCII, if the character is less than hex 20, it is a letter of the alphabet, so we should be in letters shift.

If it is greater than hex 20, we should be in figures shift. Line 1500 reduces the character to either a hex 20 or a zero value. This is compared to the value in LAST+1 (line 1510) to determine if the printer is in the correct shift. If it is in the correct shift, the program jumps ahead to send the character; otherwise, the appropriate shift is sent (1550-1630).

ASEND (1640) branches to send the character then to SAVX (1680) to restore index register and "B" accumulator and return.

Lookup (1710) does the actual conversion and stores the Baudot character in SEND+1. In lines 1730-1750, the UART is tested to see if it is ready for a new character. 1760-1770 sends the character to the UART. 1780-1820 strobes the UART to tell it that the character can be sent.

Software to input a character is listed in the November article and will not be repeated here.

These two programs do not represent a complete system for RTTY operation, but rather a set of subroutines to be incorporated in such a system. A complete system would need a software FIFO and some form of sense switch operation, so you would automatically switch from the input program to the output program when your transmitter is keyed.

The program listed here can be used to give hard copy on your existing program.

The procedure for finding the correct places and the patching procedures were outlined in my earlier (March, 1978) article.

I would like to say that I am not sure how much of this is my own work and how much was Doug Schwab WA4ZV1's. Anyhow, thanks to Doug, and thanks to the repeater gang. ■

Photos by WA4KIL

Hy-Gain's "tiger on 20," the popular 204BA 4-element monoband yagi, exhibits the excellent performance which can be obtained from a relatively small close-spaced yagi array. For over a decade, the one at K4FK has been performing flawlessly and giving no maintenance problems. Originally, the antenna was up 77 feet on a Rohn tower. A move to a new QTH in 1971 limited us to mounting it on a telescoping TV mast at heights between 12 and 20 feet (see Walker and Mazzagatti, "The Towerless 'Tower,'" *73 Magazine*, June, 1978). Even at such low heights, the 204 has proven itself competitive in pileups.

With the recent upturn in the sunspot cycle, we decided to try interlacing a 15 meter yagi with the 204BA on the Hy-Gain boom. According to *The ARRL Antenna Book*, "It is generally accepted that interaction, if any, is very minimal between bands which are not harmonically related." Would this hold true in practice? Our empirical experimentation has essentially validated that quotation. The result has been a much more versatile antenna, with no degradation in 20 meter performance.

We began by constructing one 15 meter element and placing it near the boom. The swr on 20 meters immediately jumped to 1.7 to 1 from 1.3 to 1. Moving the 15 meter element along the boom and rotating it in and out of the plane of the 20 meter elements produced no further changes. As soon as the 15 meter element was placed within a yard of the boom, the swr climbed. We moved it further away, and the swr returned to normal. We tried the same experiment using a 10 meter ele-

Photo A. A most unorthodox 204BA. Nine elements and two gamma matches radically alter its appearance!

Photo B. A view of the "business end." The result is usually heard around the world.

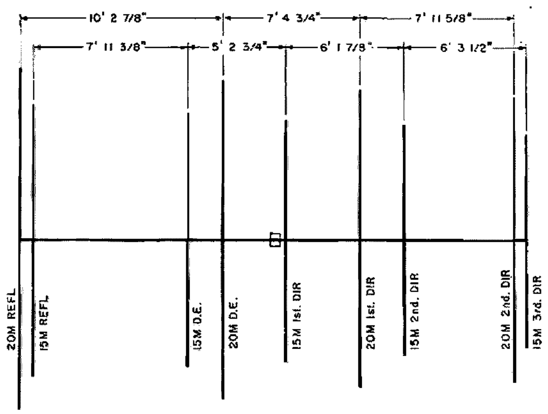

Fig. 1. Element spacing.

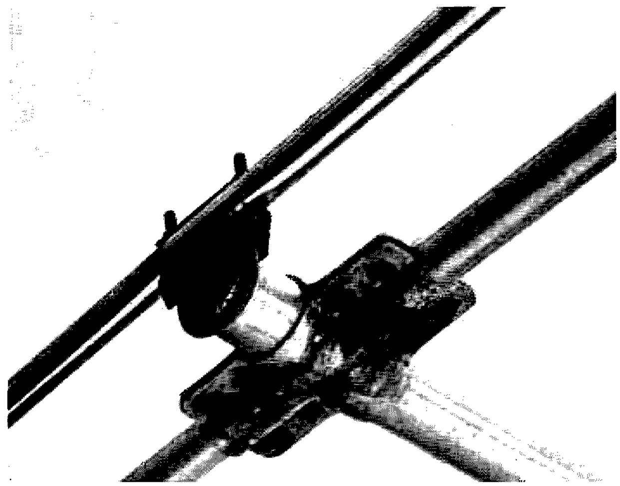

Photo C. Despite using just one muffler clamp per element, there has been no difficulty maintaining alignment.

ment, and, interestingly enough, this had no effect on the 20 meter swr. Bringing a Hy-Gain DB10-15A 3-element trap duobander close to the 204 produced a similar effect to that produced by the 15 meter element alone. Obviously, there was some interaction. Was it sufficient to reduce the 20 meter efficiency?

We tested for any 20m degradation by mounting three 15m elements on the boom and then using the beam normally on 20m over a period of several weeks. The additional elements did not increase the interaction over that introduced by the initial element, and we could detect no difference in the beam's 20 meter operation. If the 15 meter beam would function correctly, there appeared to be no reason why we couldn't interlace it with the 204BA. It would be desirable to provide an easily-adjusted matching system for each of the yagis, however.

One thing which we had noticed over the years of using the antenna at extremely low heights was how profoundly its capacitive coupling to the building was reflected in impedance excursions during rotation. Most annoying—rotate the array a few degrees, and then retouch the transmitter tuning. The better the antenna and feedline are matched, the less pronounced this effect becomes.

20 Meter Modifications

Hy-Gain's beta match is an inductive "hairpin" type of matching device. We decided to replace it with a more easily adjusted gamma match. Commercially manufactured coaxial capacitor-style gamma matches are much easier to install and maintain than are those which require a separate air variable capacitor in a waterproof enclosure. Viking Instruments* and Gotham Antennas** both market such a gamma match. We settled on the Gotham unit because it is a lower-Q device, which makes adjustment easier and less critical. Additionally, the Gotham gamma match is mechanically stronger and doesn't tend to fill with water and short out, as did two of our Viking matches.

The Hy-Gain driven element is split at the center for use with the beta match. We made it into a one-piece element by wrapping heavy-duty aluminum foil over the plastic center insulators and out over the element.

*Viking Instruments, 73 Ferry Rd., Chester CT 06412.

**Gotham Antennas, 2051 N.W. 2nd Ave., Miami FL 33127

An ohmmeter check showed that once the driven element halves were installed in the element-to-boom bracket, continuity was excellent. The aluminum foil should be covered with electrical tape and waterproofed by coating the tape with a sealant such as a popular uncured silicone rubber compound. For good measure, we attached a piece of coax braid between the two element halves as well.

Make sure you obtain good continuity between the driven element and the boom as well, if you plan to attach your feedline braid to the bracket which mounts the gamma match to the boom. Otherwise, attach the braid to the center of the driven element, not to its mounting bracket. It's also a good idea to run a bolt through the gamma tube itself for attaching the coax center conductor rather that relying on the U-bolt as the instructions suggest.

The length of the driven element wasn't altered from Hy-Gain's CW specification. The beta match, being an inductive device, probably requires a slight shortening of the driven element. Our method of making the driven element into an electrically one-piece element effectively lengthens it slightly. Therefore, resonance does not noticeably change. One additional benefit occurs as a result of this conversion. The 204BA will now display better bandwidth characteristics across the entire 20 meter band.

15 Meter Construction

Fig. 1 shows the spacing of both sets of elements along the boom. We had originally constructed the antenna with the 20 meter reflector mounted at one end of the boom, and the remainder of the elements spaced according to Hy-Gain's instructions. This left 2 inches of boom unused beyond the 20 meter second director. We chose to mount the 15 meter third director in this area to maximize its spacing. If you don't have room to do this on your particular 204BA, you can move that director inside of the 20 meter second director

Element	Length
Reflector	23' 5-1/2"
Driven Element	22' 6-1/2"
1st Director	21' 6-1/2"
2nd Director	21' 1-3/8"
3rd Director	20' 8-1/4"

Fig. 2. 15 meter element lengths.

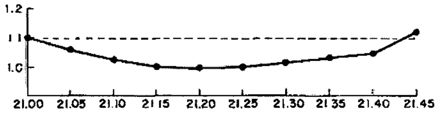

Fig. 3. Swr curve across the 15 meter band.

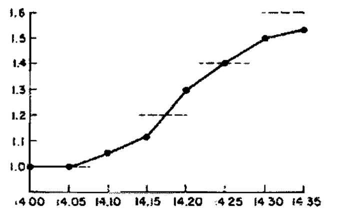

Fig. 4. Swr curve across the 20 meter band.

without affecting performance.

The boom of our 1968 vintage 204BA measures 26 feet, 2 inches. We needed to use it all if we were to mount 5 elements. Also, we had to locate some of the 15 meter elements very close to existing 20 meter elements. For these reasons, we dispensed with the usual aluminum element-to-boom mounting plates such as those used by W8ZCQ in his article, "Working 15m with a 20m Beam," *73 Magazine*, June, 1978.

Photo C shows how a single 2-inch muffler clamp can be used to mount each element. If you can't get muffler clamps with a long U-bolt, you may have to use hardware-store U-bolts with the saddles from your muffler clamps. The U-bolt must be long enough to come up through the element. We have had no trouble with elements slipping or otherwise coming out of alignment, and the array has withstood winds gusting to 56 mph.

Each 15 meter element is constructed of two 12-foot lengths of 3005 aluminum tubing. Make the center of each element from a single 1-inch diameter run. Cut a single run of 7/8-inch tubing into two 6-foot lengths. These are inserted into the ends of the center section. The ends of the center section should be Xed with a hacksaw so that hose clamps can pull it down snugly over the end sections. Our 1-inch tubing has a wall thickness of .041 inches, while our 7/8-inch tubing has a wall thickness of .035 inches. This combination produces a nicely telescoping assembly.

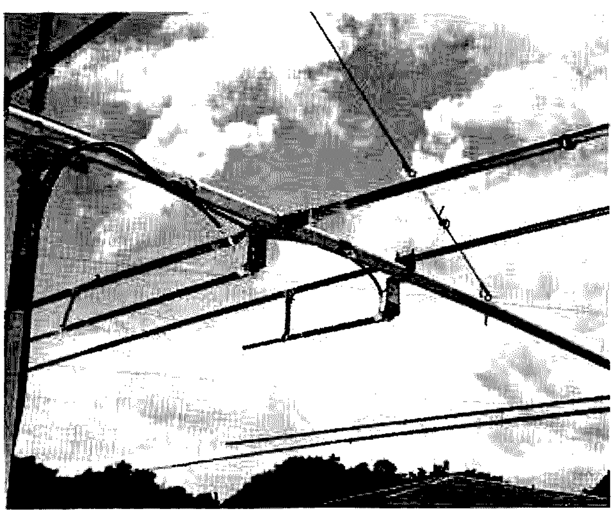

Photo D. White material on the gamma matches and over the electrical tape is GE Silicone Seal.™ It also protects the aluminum foil on the 20 meter driven element.

Adjustment

The gamma matches are adjusted in the normal manner, 20 meters first, and then 15. A good starting point for the shorting strap is a distance of 10 percent of the total length of the driven element, out from the center of the driven element. Preset in this fashion, both sections displayed an swr of less than 1.8 to 1 prior to any additional adjustment. Slide the coaxial capacitor part of the gamma match in and out until lowest swr is obtained. Then move the shorting strap a half inch and readjust the coaxial capacitor. By alternating these adjustments, you should easily find a combination which yields an swr of 1.2 to 1, or less.

It is ideal, of course, to adjust the gamma matches with the antenna in its final operating position. Most of us cannot accomplish this. We have found that the swr changes only slightly once the antenna is installed if it has been carefully adjusted either on top of a ladder or pointed vertically into the air with its reflector resting on the ground.

Performance

Figs. 3 and 4 show the swr curves on the 15 and 20 meter bands, respectively. It is quite permissible (although purists may disagree) to use the gamma matches to "fudge" the resonant frequencies a bit, if desired. Our matches were adjusted for lowest swr at 21.125 and 14.025 MHz. The 20 meter performance remains, as far as we can observe, absolutely unchanged except for the previously mentioned improvement in bandwidth. We have no way to measure the forward gain on 15 meters. However, "if you point it at 'em and give 'em a call . . . you usually get a reply." The front-to-back ratio on 15 meters runs about 20 to 25 dB and the front-to-side is just about 40 dB.

Some Thoughts

We were so pleased with this project that we decided to try to add 10 meters as well. Predictably, the interaction was so bad that we had to forego our attempts to triband the 204BA. The 10 meter elements didn't affect the performance on either 15 or 20 meters. We were just unable to make the 10 meter section perform as a beam. One set of adjustments gave us a slight bit of gain—off the reflector! Another set provided an omnidirectional pattern with signal levels about three S-units under a dipole. In no case did it make any difference whether the 10 meter elements were insulated from the boom or not. We would very much like to hear from anyone who successfully adds both 10 and 15 meter elements to a 204BA. That would surely be a most impressive tribander!

Parts Availability

In cooperation with Gotham Antennas, we are offering a complete kit to interlace five 15 meter elements with an existing 204BA. Elements, hardware, both gamma matches, and instructions are included. Please send an SASE for details.■

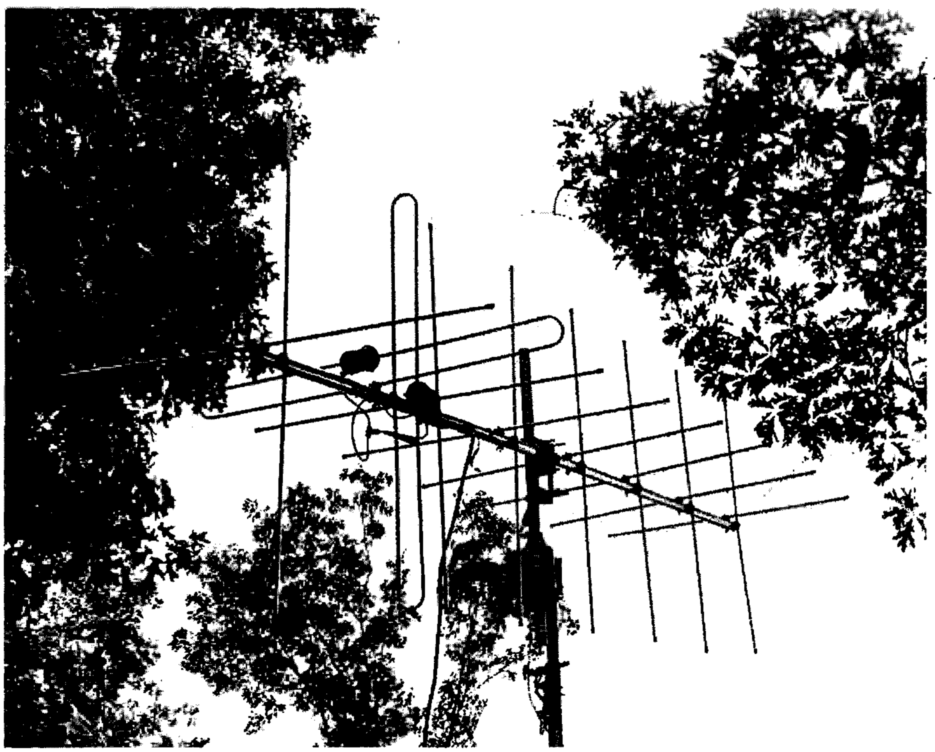
Here's a "Twist"

—an OSCAR antenna with a difference

Introducing the 8XY/2M.

Dave Ingram K4TWJ
Eastwood Village No. 1201 S.
Rt. 11, Box 499
Birmingham AL 35210

If you are one of the many amateurs who has experienced communication via our OSCAR orbital satellites, you know the challenge and enjoyment of satellite operations. The various aspects of OSCAR communications have something to catch nearly everyone's fancy: convenient operating times, orbital calculations and tracking systems, duplex style operating, unobtrusive antenna setups, low TVI levels, etc. Amateurs with limited time available to enjoy on-the-air operations truly appreciate the pinpoint-accurate communication times synonymous with satellite passes. What else could one ask?



The Spectrum International 8XY/2M OSCAR antenna is mounted on a 30-foot push-up mast which is tilted 30 degrees. This "skyward tilt" bypasses elevation rotor needs.

As with any station setup, the antenna system plays a major role in its performance. Quite simply, it's what's "up top" that counts! A poor skywire can undermine the most elaborate amateur setup, while an efficient antenna can make a mediocre setup perform like a million dollars. OSCAR setups are no exception to this rule. If you plan to fully enjoy OSCAR, you'll definitely benefit from using an antenna designed for satellite operations. Such an antenna is the 8XY/2M 8-element, 2-meter "Twist" antenna distributed by Spectrum International.

I found that assembling the 8XY/2M antenna was a refreshing change from the usual time-consuming task of rigging clamps and measuring element mounting locations. This gem went through smoothly in an hour's time, with heavy-duty bolts and wing nuts making hand-assembly a snap. Not a single tool was required until transmission lines were connected to

the driven elements. Each element of the S.I. "Twist" is ¼-inch aluminum tubing which is precut and capped with color-coded tips to aid assembly. The boom is also predrilled and color-coded to ensure quick, foolproof assembly. *All* hardware for the antenna is *preassembled*, and an extra element-mount is included in case one becomes lost or broken. The massive boom-to-mast clamp could support a triband beam. Very nice! I must admit that this was the first time I've enjoyed (sort of) constructing an antenna.

The 8XY/2M antenna can be fed four different ways to obtain either vertical, horizontal, right-hand circular, or left-hand circular signal polarization. A ready-to-install phasing harness for circular polarization is available from Spectrum International, or you can fabricate your own harness from details supplied in various antenna books. Since I didn't care to kill time building a harness, I used the S.I. unit—and I'm glad I did.

If a fixed polarization is desired, the harness can be mounted at the antenna proper. If various polarizations are desired (for operating various modes of OSCAR), two transmission lines can be run from the antenna's driven elements and the phasing harness placed at the operating position. A coax switch can then be used to select the required polarization.

My Spectrum 8XY/2M antenna replaced a 2-month-old, 3-element array previously used for satellite work, and a significant signal improvement was realized. Suddenly, I was able to easily access the satellite and "stay into" the transponder for a longer period of time during each pass. I also noticed that my signal wasn't as prone to the heavy fades which were apparently due to polarization shifts during passes. This gain alone was worth the change to Spectrum's 8XY/2M antenna, as it allowed me to successfully operate slow scan TV via satellite.

When OSCAR 8 was placed in orbit, I decided to remove a few director elements from the 8XY/2M to reduce my erp to this new "bird." This antenna change worked very well, but a couple of days later, OSCAR 8 lost sensitivity and I had to replace the removed elements. Hopefully this satellite problem is merely an overloading situation which will soon be rectified.

I truly feel that the 8XY/2M antenna was a prime factor in my operations of successfully transmitting the first SSTV pictures via OSCAR 8 during orbit 102. Since I have only one small TV rotor to use with the 8XY/2M, I bent the rotor-to-boom mast approximately thirty degrees. This tilt allows the antenna to "look skyward," and bypass elevation rotor requirements.

In conclusion, I think amateur satellite communication and Spectrum's 8XY/2M are an ideal combination which all amateurs would thoroughly enjoy experiencing. There's no better way of renewing one's interest in amateur radio than by trying a new aspect of communication.

The 8XY/2M antenna is available from Spectrum International, Inc., P.O. Box 1084, Concord MA 01742. This 16-element array (8 elements vertical, 8 elements horizontal) is in the $45 to $50 price class. ■

A Fortified 2m Whip

—won't bend in the breeze

Donald A. Habeck W9AMM
5973 Sugarbush Lane
Greendale WI 53129

Are you in need of a good 2 meter mobile antenna? How about an antenna for your base station? Or, do you just plain have the feeling that your station has become too commercialized and that a portion of your setup should be home-brewed? Then, why not try this antenna project? In actual checks, it was found to compare favorably with the commercially-made antennas tested. Whether you decide to use the antenna for mobile or base station operation, you'll be pleasantly surprised with its performance. The antenna is easy to construct and tune, and, best of all, it's inexpensive.

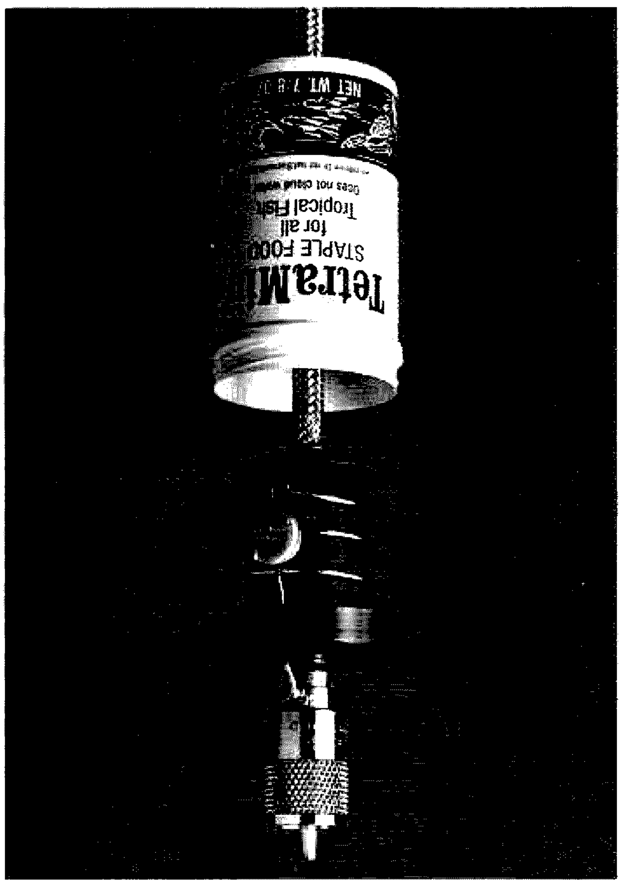


Photo A. The coil protective cover has been removed in this picture to show details of the base coil.

Design

One unique feature of this antenna is the construction of the whip. It consists of a 1/4"-diameter fiberglass rod with a shield of copper braid. This design was selected because it provided rigidity to minimize deflection during high winds or mobile operation. Research has shown that deflection of the flimsy-type whip causes degradation of the vertically polarized signal. In some instances, the efficiency of a 5/8-wave antenna actually becomes less effective than a 1/4-wave antenna.

The fiberglass rod is from the pennant-topped-type whip that is made for mounting on bicycles. Many retail stores have given away these whips as promotional items. They also are readily available from department stores and bicycle shops for approximately $1.25.

The impedance matching coil is 3 turns of no. 14 tinned copper wire wound on a wood thread spool from your XYL's sewing basket. It is tapped 1-1/8 turns from the ground end. A small ceramic trimmer capacitor across the coil provides a precise match in conjunction with the base coil tap. The impedance matching circuit is protected from the weather by enclosing it in an empty plastic container. Fish food had come in the container we used.

Construction and Assembly

Since no tricky construction or special tools are needed, no problems should be encountered. The fiberglass rod is prepared by drilling the 1/16"-diameter hole from the bottom as indicated in the diagram. Another 1/16"-diameter hole is drilled on the side of the rod at point A. This should be drilled at a slight angle towards the bottom to make the routing of the coil tap wire easier. The depth of this hole is only to the extent of meeting with the hole previously drilled from the bottom. When drilling these holes in the fiberglass rod, it is important to use a sharp drill and not allow the drill to heat up. It is best to cut the whip to proper length after the coil form is secured in place.

Prepare the coil form and other parts as indicated. Check that the hole in the spool is of the proper

diameter to permit the spool to slide on the rod. The notches filed into the coil form prevent the coil from slipping. The hole for the coil tap is displaced 1/8 of a turn from the alignment of the bottom notch.

After the coil form is prepared, feed the 20-AWG tap wire through the tap-wire hole and out the bottom of the spool. Slide the form over the fiberglass rod and carefully route the tap wire through the drilled hole at point A and downward through the rod, out the bottom. Allow sufficient length for the tap wire to be soldered later in the PL-259 connector. Apply epoxy glue to the appropriate rod area, slide the coil form into its proper position on the rod, and take up any slack in the top wire. The final position of the coil form should be such that the tap-wire holes in the spool and the rod line up with each other and the rod extends sufficiently below the bottom of the spool to accept the UG-176 adapter. To hold the tap wire securely in position, apply a small amount of epoxy to the tap-wire opening in the spool and at the bottom of the whip.

Two holes must be drilled in the cover of the coil protector. A 1/4" hole in the center will permit it to be slipped over the bottom of the whip. With the cover in position on the whip, use the notch of the coil form for determining the position of the second hole. This is a 1/8" hole and should be drilled in the correct position to allow the ground end of the coil wire to pass through the cover and be soldered to the PL-259 connector. After both holes are drilled in the cover, epoxy the cover (threads towards the coil form) to the bottom of the wood spool. Position the feedthrough hole in the cover so that the tap occurs at 1-1/8 of a turn when the coil is added.

With epoxy applied to the bottom of the fiberglass rod, slide the UG-176 reducer onto the rod and up against the container cover. Check that none of the other parts has slipped from its proper position. At this point of construction, it is best to allow the epoxy to harden before proceeding.

After the epoxy hardens, the UG-176 reducer can be screwed into the PL-259 and the tap wire soldered in the center pin. Measure 42½ inches from the top of the coil form and cut the whip to length.

The next step is to slide the copper braid shield over the fiberglass rod. Tinned braid is recommended. However, if this is not readily available, the shield from RG-8/U coax cable will work fine. If the braided shield is too snug to readily slip over the rod, the diameter of the shield can be enlarged by squashing the braid together a little bit at a time. If the diameter of the shield has to be enlarged to any extent, be sure to allow for the shrinkage in length that will occur. The braided shield is slipped over the full length of the rod down to the coil form. The shield can be snugged to the rod by running your hand tightly along the braid.

One end of the coil is secured by routing a 24" piece of 14-AWG wire through the hole in the cover and soldering it to the side of the PL-259 connector. With the one end secured, the 3-turn coil can then be easily wound on the form and soldered to the whip shield. Solder the tap wire 1-1/8 turns from the coil bottom (ground) and the trimmer capacitor across the entire coil. Cut off the braid shield so that it extends 3/8" above the top of the rod; twist and

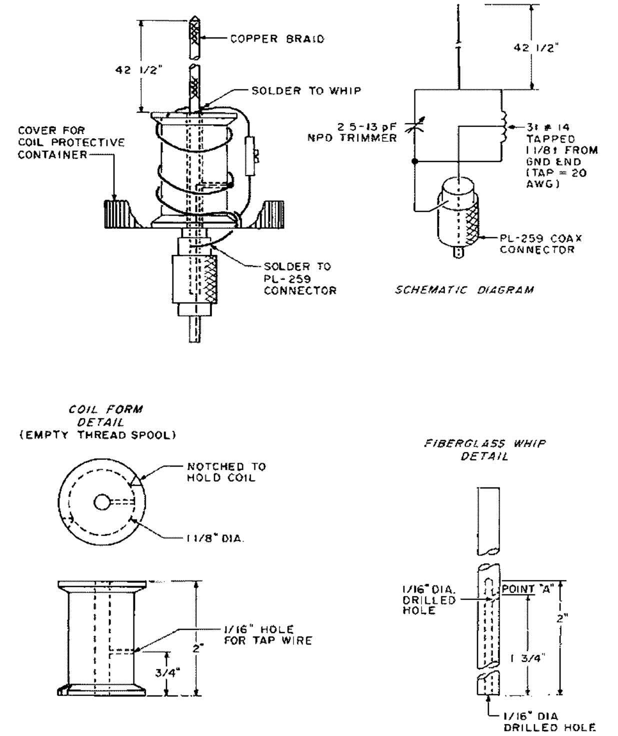

Fig. 1. A rigid 2 meter antenna for base or mobile operation.

solder. To protect the whip from the weather, shrink tubing, plastic electrical tape, or a protective spray can be used.

Mounting

For base station operation, I used a simple L-shaped aluminum bracket with an SO-239 connector, RG-58 coax, and four 19¼" ground radials. This arrangement is secured with U-bolts to the mast above a triband beam. For mobile operation, the bracket design is dependent on the type of car and individual desires. For my mobile operation, I mounted a simple bracket and connector arrangement directly to the luggage rack.

Tuning

The easiest method to tune the antenna is with a field-strength meter at a distance of approximately 2 to 3 feet. With the antenna connected and the transmitter keyed on an unused simplex channel, adjust the trimmer capacitor with a non-metallic screwdriver for a peak field-strength indication. The vswr will be minimum at this point. Numerous antennas have been built, and, on all occasions, vswrs of less than 1.2 to 1 were obtained. The antenna, of course, should be situated away from all objects and as high off the ground as practical during tuning procedures.

With a 5/16"-diameter hole drilled in the bottom of the plastic container to accommodate the whip, slide the container over the whip and screw it into its cover. If the container affects the tuning of the antenna, drill a hole in its side and retune the antenna with the container in position. With RTV, seal the top opening of the container, but not the bottom. The hole in the cover will help prevent any moisture from accumulating.

Do you want to generate conversation? Just mention on your local repeater the fact that you're using a home-brew antenna.■

Ageless Wonder: the Collinear Beam

—sure beats a dipole

Good results for a few dollars.

C. Stewart Gillmor W1FK
Spencer Road
Higganum CT 06441

Ever since the ready availability of aluminum tubing after the second World War, yagi beams have been popular with hams. More recently, quads have joined as popular antennas for the HF bands. These parasitic array antennas have a number of attractive features, including high gain, unidirectional radiation, and rotatability. Realization of their full potential, however, requires relatively expensive support equipment, including tower and rotor.

I have enjoyed using collinear wire beams, which give reasonably narrow bidirectional radiation patterns. These arrays are composed of elements arranged in a straight line. Each element is connected to the next by a phasing stub so that all elements operate in phase. The collinear antenna is often used at VHF and UHF in vertical orientation, but at HF it is only practical to erect horizontal collinear antennas. Collinear antennas have long been used in military applications, or in any situation where need exists for a rugged, directive HF antenna which can quickly be erected and which can deliver good performance. Especially for the Novice or for the ham on a budget, the collinear should be considered because it is easy to construct and it is inexpensive.

Many antenna texts discuss collinear antennas, but few provide complete design information. Particularly omitted is information on impedances. Collinear antennas may use elements of varying electrical length, but most common is the one-half wavelength element. Collinears may have as many as 6 elements. Because of mutual coupling and increasingly uneven current distribution obtained as one adds elements, most hams have built collinears with 2 or 3 elements. Highest gain is obtained if the antenna elements are spaced with 0.4 or 0.5 wavelengths of space between the ends of the elements, but this introduces construction problems. Less gain but much simpler design results from separating the elements only by use of an insulator.

I give design criteria below for 3-element 20 meter and 5-element 15 meter collinears, each of which requires less space to erect than an 80 meter dipole. I also give data on impedance characteristics at and near resonance to aid in selecting a suitable feedline. Many collinears are fed between the ends of the elements, where a very high impedance exists. In the antennas described below, feed occurs in the center of an element at a relatively low impedance, high current point. This permits a good match to 300- or 600-Ohm balanced lines. If one prefers, a 4:1, 6:1, or 9:1 ratio balun may be inserted so that the antennas may be fed directly with coax. My collinears are fed with balanced line, and a balun is introduced just outside the shack.

I was not able to find information on the impedances met when feeding collinears at current points, so I performed measurements on 3- and 5-element collinears suspended ¾ to 1 wavelength above ground. The impedances were measured on my Boonton 250-A "RX" meter. The impedance at resonance of the 3-element centerfed antenna was found to be 372 Ohms resistive; the 5-element antenna showed an impedance at resonance of 600 Ohms. Each of these antennas operates across an entire ham band with vswr of less than 1.5:1 (±1% of design frequency), using no matching device except a

Frequency	Dimensions			½-wavelength in feedline	
				coax V = 0.66	twinlead V = 0.82
	A	B	C		
21.2 MHz	11' 4"	22' 7½"	9' 6"	15' 4"	19' 0"
14.15 MHz	16' 6½"	33' 1"	14' 3"	22' 11½"	28' 6"

Table 1. Dimensions as measured for 15 and 20 meter collinears. A = halves of center element; B = outer elements; C = matching stubs.

properly chosen balun. The transmission line is chosen to be an integral number of half wavelengths. Of course, a balanced line tuner may be employed and the balun omitted. One can also tap up and down the transmission line for impedance matching purposes if this method is desired.

It is worth pointing out that the velocity of propagation of electromagnetic waves along transmission lines varies with the dielectric material used in constructing the line or cable. This velocity factor (V) must be included in calculating electrical wavelength in various types of lines. For example, open-wire line can be assumed to have a velocity factor of nearly 1.0 (or perhaps more exactly, 0.95 to 0.975). Thus, a wavelength in free space is nearly the same as one measured along open-wire line. The coax cable usually used by hams has a V of 0.66, and most 300-Ohm polyethylene balanced line ("twinlead") has a V of 0.82. This means, for example, that a wave of 15 meters length in free space has a physical length in coax of about (0.66 × 15m) = 10 meters and a physical length in 300-Ohm twinlead of about (0.82 × 15m) = 12.3 meters. In the designs below, I use 300-Ohm twinlead for the ¼-wave matching sections.

The 3-element collinear achieves a gain of about 3.3 decibels over a simple half-wave dipole and has a beamwidth to the half-power points (where the field strength voltage drops to 0.707 of its maximum value) in the horizontal plane of about ±18°. This is for a horizontally oriented antenna, of course, and the radiation is greatest at right angles to the axis of the array. The 5-element antenna achieves a gain of about 5.3 decibels and a beamwidth of about ±10° or so. Each antenna's horizontal radiation pattern is bidirectional with minor side lobes. I have designated the centerfed element halves as "A" in the drawing (Fig. 1) and in Table 1, the pairs of outer elements as "B", and the matching sections as "C", for the case of the 3- or 5-element centerfed collinear.

Construction Hints

All half-wave elements should be of equal length in a given antenna. One can erect the centerfed element and adjust it to exact resonance, if desired, then add the stubs and outer elements. Velocity factor V was found to be 0.95 for the 3-element collinear. The 5-element collinear resonated slightly higher than the calculated frequency; evidently a V of 0.95 overcorrects for end effects. I found V here to equal 0.975, and I give the actual determined dimensions for each antenna in Table 1.

I used home-brew nylon insulators which are 2 to 3 inches long and cut out of scrap. They are light and tough. One could also use Plexiglas™ or some other material or commercially-made ceramic insulators.

The phasing sections could be of open-wire line (remember, then, V would be about 0.95), but I chose 300-Ohm twinlead because the stubs tend to blow around in high winds and ladder line might twist up and short. (Also, I had a few scrap pieces of 300-Ohm twinlead in the shack.)

The antenna elements themselves I made of odds and ends of #16 and #14 hard-drawn copper wire, but almost anything will do here.

Care should be taken to fasten the phasing stubs to the insulators so that they do not fatigue and break off. Solder the stubs closed at the ends. I suspended the collinears high in some maple trees using clothesline pulleys and ¼-inch nylon line. One has been up for two winters and has survived numerous ice storms and high winds. You might wish to silicone or wax the twinlead to minimize swr changes during rainstorms. I'm not fussy about these antennas, except that I make sure that I never erect an antenna near, over, or under a power line.

In Table 1, I have given actual dimensions for center frequencies of 14.15 MHz for the 3-element and 21.2 MHz for the 5-element antenna. I use these collinears for working into Europe with my Triton IV. The 15 meter collinear would make a dandy antenna for Novice DXing. If one has the space for an 80 meter dipole, then 2 or 3 hours invested in construction and erection of a multi-element collinear will probably result in surprise and pleasure that such a simple antenna brings such good results for only a few dollars. ■

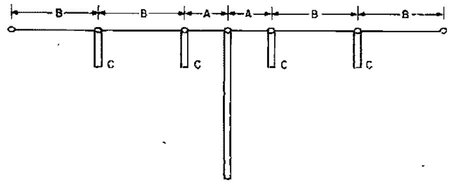

Fig. 1. Centerfed multi-element collinear wire beam. A = ¼ wavelength (ft.) = 246 (0.95)/f_{MHz}; B = ½ wavelength (ft.) = 492 (0.95)/f_{MHz}; C = ¼ wavelength (ft.) = 246 (0.82)/f_{MHz}.

Three Baluns for a Buck

—go find yourself a junked TV

Better than mail-order.

Editor's note: This article was written while the author was in Iran. He has since returned to the United States.

Donald E. Lively W6SJQ
9 Wedgewood Drive
Millington NJ 07946

Activating an HF radio station in areas of the world where hamming is not too common calls for a certain amount of improvisation. This is particularly true if station logistics have not been carefully planned prior to leaving home base.

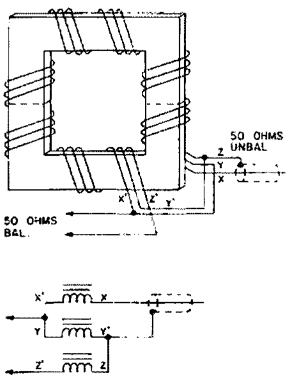

Fig. 1.

Material Selection and Preparation

The problem facing this station was that of acquiring a balun for a three-band dipole and then a three-element beam. Experiments with a homemade balun in the US using the ferrite core of a defunct TV flyback transformer had been quite successful on 80 and 40 meters. It was decided, therefore, to see if the same approach would do for 20, 15, and 10. It figured that a core material able to handle the TV horizontal retrace without significant loss should be fairly good for HF radio transmission. Actual measurements through the finished balun at 28 MHz and lower frequencies show less than a ½-dB attenuation.

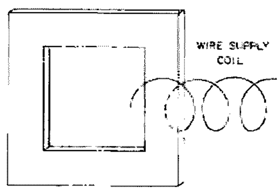

Fig. 2.

Initial Construction

Actual construction was started in the following fashion. A burned-out flyback was obtained from a TV service shop, and all of the windings, plus sealing compounds, were removed. After disassembly, two C-shaped core halves remained. These are normally mated at their highly polished surfaces and clamped together to form a solid O-shaped rectangle. To avoid any shorted turn effects from the clamping arrangement, and to make unobstructed space for windings around the full core circumference, the two core halves are held together with an epoxy compound. A very thin film of steel-filled epoxy is used for this purpose—hopefully this minimizes discontinuities in the magnetic circuitry of the core.

Some further core preparation is still needed before putting windings in place. This includes removal of any sharp edges with a fine file or abrasive cloth (to avoid scratching the enameled wire). The last step of preparation is to place two layers of plastic or glass tape over the core—this gives a very smooth surface for the winding process.

The actual winding calls for considerable care if a low swr is to be realized. Considerable experimentation took place to get best results—and two precautions turned out to be important in getting good balance and low loss: sym-

metrical placement of the turns and uniform "turn shape." The results of this care are uniformly distributed capacity within and between turns and equal inductance for each of the three trifilar windings.

The way the tight and uniform turns are achieved is to employ a modification of the "bobbin" technique (see Fig. 2) used on commercially-wound toroids. For this application, start with a single piece of about no. 20 gauge wire approximately 18 inches long. Thread the wire repeatedly through the core center until eight turns are in place. Distribute the turns evenly and clip all but about two inches on each end of the winding. Remove this temporary winding, straighten it, and measure its length. This will be the length of the permanent windings. Cut three lengths of no. 14 Formvar or similarly insulated copper wire and wind each one around a D-cell battery or similarly sized form to create the "wire supply coil" for the finished balun.

Next, take one of these coils and "screw" it onto the TV transformer core. Do this by spreading the turns and placing an end through the center hole, rotating the coil until it is all on the core. Straighten one end of the coil so that the 2" excess extends out from the core, then press tightly against the core this first turn of the "wire supply coil." Use your thumb to force each turn of the balun into shape against the core. Form each turn diagonally so that two turns are placed on each side. (Depending on where you wish to make your connection to the antenna and transmission line, you may start and finish at a corner or a side.)

Repeat the process for each of the next two windings. To keep the turns tight so that their final spacing can be evenly positioned, temporarily twist the two ends of each coil together. This will prevent any unwinding. Place a few drops of 5-minute epoxy glue at the point where windings start. When the windings are firmly set and evenly spaced, wire and solder them as shown in the diagram of Fig. 1. Be especially careful to make the connections between the windings symmetrical (to ensure equal inductance and coupling). Failure to do this will create a poor swr and increase loss. (An associate of mine has run tests on several commercial baluns and found that inattention to this matter accounts for fairly wide variations in performance, particularly at the higher frequencies.)

You are now ready to attach the leads on the balun which connect it to the feedline and antenna. Mount a coax fitting at one corner, and for the feedline, and the flexible leads (short lengths of coax outer conductor braid) for the dipole connection.

Final Adjustments

With a short length of coax, connect the balun through an swr bridge to a transmitter with variable output carrier. Connect the flexible leads to a dummy load, being careful to keep them straight, symmetrical, and evenly spaced. (Pieces of RG-58 outer covering can be used to protect the leads from the weather and to avoid shorts during the tests.) Next, set the rf source on 28 MHz and apply enough power to get a good reading on the swr meter in the forward direction. (Run the power high enough to ensure that the transmitter output "looks like" its transmission-line drive impedance—with some solid-state rigs, this may vary at very low power settings.)

Switch the swr meter to reverse and observe the reflected power level—it should read 1:1.2 or less. If it's higher, remove the rf power and try evening up any irregularities in the windings or significant spaces between adjacent wires in the individual turns. With careful dressing of the turns and connecting leads, this kind of performance can be realized.

The transformer (balun) is now ready for final assembly and mounting. Numerous schemes are appropriate. For my application, no enclosure was used, but just encapsulation in epoxy with a piece of vinyl tubing threaded through the center to tie the unit to the beam boom. (This was because an earlier model placed in a metal can arced to ground from a nearby lightning strike.) An appropriate form to contain the epoxy while it sets was made from the sides of a polyethylene detergent bottle. This material can be "welded" using a soldering iron to melt and join edges of individual pieces to form the desired shape of container.

Incidentally, the 30¢ cost refers to the wire—it has to be purchased locally. The epoxy is, of course, optional and is an added expense. The TV transformer core was a gift from a friendly Iranian TV repairman—a similar acquisition is no doubt possible anywhere.

The balun has worked fine and is superior to a mail-order kit which has been rebuilt numerous times but which has never given a satisfactory 10 meter swr when connected to a very load-match-sensitive Atlas 210X. ■

So You Want to Raise a Tower

—do it safely, do it right

A simple guide to an important subject.

James Wyma WA7DPX
513 W. 10th St.
Casa Grande AZ 85222

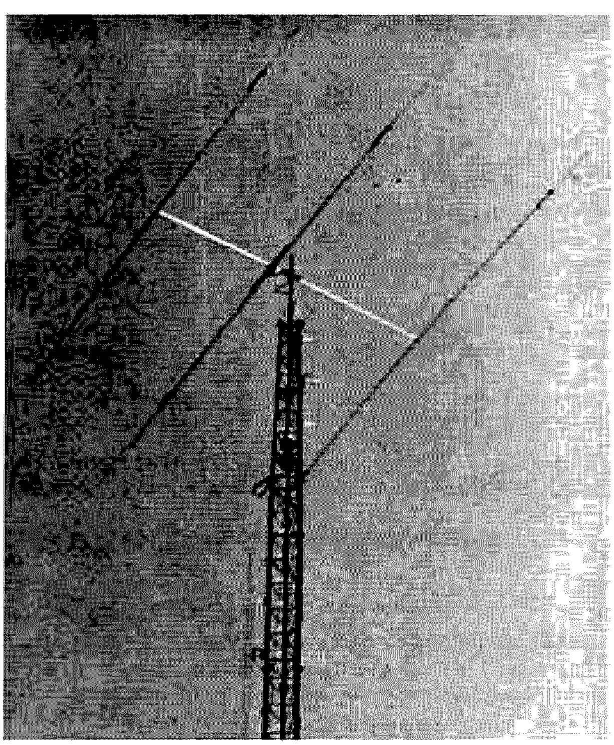

Photo A.

Sooner or later every ham has the desire to put up a tower. The intent of this article is to save you from some of the problems you can have by improper installation of your tower. These problems can result in loss of your tower and antennas, loss of your ham shack (a falling tower can do a great deal of remodeling to your shack), and last, but not least, loss of your or someone else's life. The first two losses can be corrected; the third can't!

First off, let's establish some basics. There are only two *safe* ways to erect a tower: with a crane or with a gin-pole. If you have the money, the first is the easiest. The second method is the one used by those of us who have more time than money.

Assuming that you have decided on the second method, you will have to do some tower climbing. There is one very important principle involved in tower climbing. Simply stated, it is: "If you are unable to strap a safety belt on the tower, let loose with both hands and lean back comfortably for a short nap, then keep both your feet on the ground."

If your legs are shaking, your hands are white from hanging on, and all you can think of is "I'm going to die," then you have no business on a tower!

Try the technique that I use. Tell yourself that once you have climbed more than ten feet, you probably will be killed if you fall. If you don't like this approach, you should get someone else to do the climbing.

Once you have doubled your life insurance—or found some tower rigger to do the climbing—you now have to decide where to put it. The ideal place is right next to the window in your shack, but this doesn't always turn out to be possible. Considerations governing tower location are as follows:

1) The guy-line anchors should be kept within your property boundaries, if at

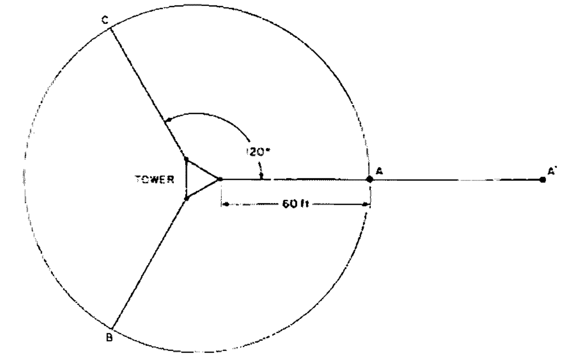

Fig. 1. Diagram for 60' tower and guys.

all possible.

2) The anchors should be at a distance of at least two-thirds of the tower height away from the base of the tower, and, preferably, a distance equal to the tower height. Example: A 60' tower should have guy supports at a distance of 40' to 60' from the base. Three guy lines are generally used.

3) The guy-line anchors should be at 120° spacing from each other. If available, a surveyor's transit should be used to site their locations. Fig. 1 demonstrates this. Note that it is not necessary to have all the anchors in a circle (i.e., equal distance from the base). This is shown by point A' of Fig. 1. Every effort should be made to keep the anchors as close to 120° apart as possible. The more you deviate from this, the more vulnerable is the tower to twisting torque.

4) Guy lines should not be obstructed by power lines, trees, or parts of any building.

5) Be sure your community has no restrictions on tower erection; obtain a building permit if one is required.

6) Make sure there are no buried water, gas, or power lines in the areas where you plan to dig your base- and guy-anchor holes. Call the utility companies; they will locate them for you free of charge.

7) If at all possible, attach the tower to your house or shack. In most cases, this will classify it so that your home-owner's insurance will cover it. Check with your agent to see if this applies to your policy, and, if it does not, ask him about a separate liability policy. In most areas, a tower is considered an attractive nuisance for juveniles, and if a child is hurt on your tower, you are at fault even though it is on private property. If your tower falls on a neighbor's house, more than "Gee, I'm sorry about that!" is usually required to fix the damage.

8) Determine that the ground where your base and anchors will be is solid enough to hold them in place. Freshly-excavated ground should be avoided. (Quicksand, mud, and earthquake faults also should be avoided.)

Now that we have the basics out of the way, let's get started on putting this thing up. The tower foundation and the guying are the two most important parts of your whole installation. Don't take short cuts in either of these areas. A few bucks saved on cheap concrete or junky guy lines could cost you thousands of dollars in the long run.

The type of ground (clay, sand, soft dirt, or whatever) and the height of the tower will determine how much concrete you need for the base and guy-line anchors. A very good place to get this information is in the Rohn tower catalog. You can probably obtain a copy of it from Rohn or your Rohn dealer. This will give you a lot of valuable information on how and where to guy your tower and how big to make your holes for concrete. Under no circumstances should the base or anchors contain less than ¼ yard of concrete.

Photo B. The base plate is anchored to the tower foundation with one bolt.

The specific information in this article is pertinent to most towers, but it is specifically related to the Rohn 25G tower. This is one of the most popular ham towers and the one with which I have the most experience.

In Photo B, you can see what I prefer for the tower base. Note that the concrete sticks up above ground level. This is accomplished by making a frame out of 2 × 4s, with the 4" side vertical. There are a number of reasons for doing this: looks, maintainability (grass trimming), and, most important, leveling. If your base plate isn't level, it will be nearly impossible to level the tower.

Speaking of the base plate, it is a good investment to make. At $40 to $45 per section, it is a very expensive practice to bury part of the tower in concrete. With my system, should you decide to move, the base plate can be taken with you. (Most people would rather not take a yard of concrete with them to get the tower section cemented in it.)

You will notice that the base plate is held in place by one 5/8" x 18" galvanized bolt in the center. If you are unable to find one at your hardware store, try your local power company. These bolts are used quite extensively for power-pole hardware.

After you have poured the concrete in your base hole and tamped the air out of it, the bolt is inserted. Don't wait too long to put the bolt in or your concrete won't hold it too well. If you are a pessimist, a 3" flat washer welded to the end of the bolt before putting it in the concrete will add holding power.

Do not attempt to put the base plate in place until after the concrete has set. Also, be careful not to bump your cement form when pouring the concrete.

Two-inch pump rods were installed to stop cars from running into the tower.

Once the base has cured (at least a week, and preferably longer), the

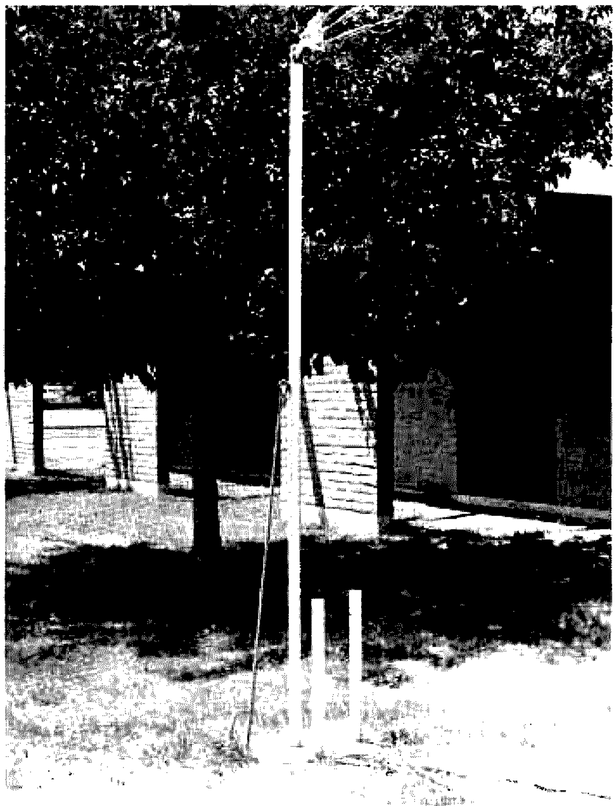

Photo C. Two types of guy-line supports are shown here.

Photo D. Guy lines are attached to equalizer plates, one of which is welded to the pump rod.

tower can be bolted to the base and set in place. Generally, the first two sections can be bolted together and set on the base without too much trouble.

Next, let's look at the guy-line supports. Photo C shows two types of guy-line supports. At the bottom of the picture is a Rohn guy anchor. This piece is cemented into the ground with just a few inches of shaft and the eye sticking out above the ground. (See your Rohn catalog for recommended installation of this device.)

Also in the picture is a pole with the lines attached to it. In this case, a 2″-diameter solid-steel pipe (a well pump rod) is used. If you check with a local pump repair company, you will find that pieces of rod that have been removed from wells are available for a couple of bucks each. Don't take your Volkswagen over to load up three lengths of this pipe, however. A 10′ piece of pump rod weighs over 300 pounds!

If you are unable to find the pump rod, a piece of 3″ or 4″ pipe will do equally well, with the pipes filled with concrete for extra strength, if desired.

The use of the pole has several advantages over the use of the guy anchor. The main advantage is that the lines are above ground so that people won't trip on them or hang themselves on them.

The hole for the anchor was 2′ × 2′ × 2½′ deep. This left 7½′ of pipe above ground, and, in most cases, this is plenty. If a driveway is crossed, you may need to go higher than that. If so, I recommend you use concrete-filled 4″ pipe rather than a pump rod. In any case, to make sure that they don't move, the pipes should be placed in the hole before pouring the concrete. The pipe also can be guyed with wire or rope attached to stakes in the ground.

Before calling your Redi-Mix company for a load of concrete, be sure that you have everything prepared. If the driver stands around while you put the pipe in the ground and guy it, you'll find that your bill will have a substantial charge for "stand-by" on it.

Photo D shows a close-up of how the guy lines are attached to the pipe. The piece of metal welded to the pipe is one of the equalizer plates in the Rohn EP-2534-3 package. When ordering, get 5 EP-2534-3 packages. There are 2 plates and hardware in each kit. Three sets will be used as standard equalizer plates, three of the remaining four plates will be welded to the pipes and the last plate always can be used as a paper weight.

Unless you are an extremely good welder, you should have the plates put on at your local welding shop. Tell the welder you want a *very* strong weld, to hold guy wires which will hold up a tower.

A few more points and tips: (1) All of the hardware shown comes with the equalizer plates, but, when ordering, be sure you get the correct plate for the number of guys that you will have. An EP-2534-3 is for two or three guys. An EP-2534-5 is for four or five guys. (2) When you set the guy-line pipe in the ground, be sure that the equalizer plate is facing toward the tower. It is very hard to rotate the pipe once the concrete has set. (3) If you want a little extra safety, you can weld a 12″ × 12″ plate to the bottom of the pump rod to make it harder to pull out of the concrete.

Once you have the base and guy supports poured in concrete, the next thing is to sit back and take a well-deserved break while the concrete cures. This will give you time to catch up on your reading of those back issues of *73*. After a couple of days, you can sand the rust off your guy pipes and spray them with Rust-o-leum, or some other rust-inhibiting paint. The silver paint seems to last the best of the colors I've tried.

Now that you are well rested and raring to go, we will start putting the tower up. We previously men-

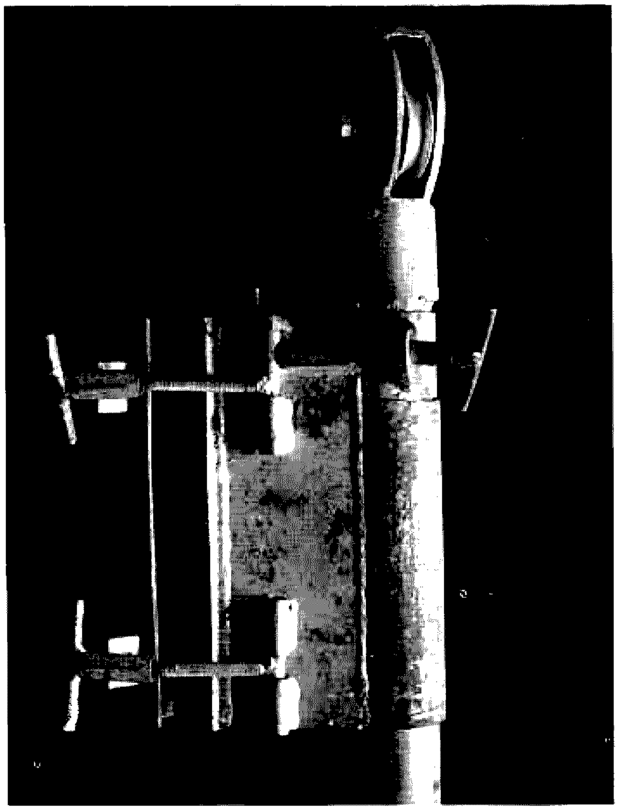

Photo E. This is what a gin-pole looks like.

Photo F. Clearing excess galvanizing from the tower legs will make joining easier.

tioned the gin-pole. Photo E shows a picture of the gin-pole, for those of you who don't know what one is. It consists of an aluminum pipe about 13′ long, a clamping device, and a pulley at the top of the pole. (If you know someone who works at a radio shop, you may be able to borrow their gin-pole.)

While you are out scrounging around, you also will need a *good* safety belt (not a World War I surplus job). Remember, your life literally depends on the belt. If it goes, you go; if your belt breaks, you will be in for a big letdown. Another need is good rope. You will need a piece as long as twice the height of the tower, plus about 30′.

Before you get gung-ho to start putting up the tower, take a few minutes to inspect the tower sections. If any of the mating ends appear to be at all bent, check to be sure that they will mate with another section of tower. If severe damage is evident, turn in a claim to the trucking company and request replacements. While you're checking out the tower, locate the mounting hardware. You will find a plug in one of the lower legs of the tower. Pry it out, tilt the leg, and catch the nuts and bolts as they slide out. There should be two sizes of nuts and bolts, and three of each size. Be sure to count all the hardware to make sure you're not short, and then place it in the pouch of your safety belt.

Two other things can be done to make the tower sections easier to put together. The first is to take a 1½″ piece of rod a foot or so long and grind a blunt point on it. Very gently drive this into the female (lower part of tower) ends of the tower sections. (Don't get carried away or you will split the tower legs open.) Photo F shows this being done. The second is to drive a drift punch through each of the bolt holes in the tower. Drive the punch in from both sides of the holes. The reason for these steps is to clear out any excess galvanizing that may be clogging the holes. (All Rohn towers are hot-dipped galvanized after they are assembled.) Under no circumstances should you use a drill to ream out the holes.

You now are ready to start putting up the tower sections. If you are doing the climbing, be sure that your ground man is reliable. Your life literally rests in his hands. If *you* say "whoa" and *he* "let's go," you have a big problem.

The man on the tower *always* calls the shots—he is the boss. If you can get hold of a pair of walkie-talkies, it will save you from laryngitis from yelling to each other. And let your ground man do as much of the physical work as possible.

The number one rule is safety. Tower work is no place to be horsing around. Before you take one foot off the ground, make the following point emphatically clear to everyone: If anything breaks, comes loose, or drops, don't try to stop it or catch it. Should anything go wrong, get your butt out of the way. A piece of mangled-up tower can easily be replaced. A mangled body is not so easily replaced.

The man on the tower should have the following equipment with him before he starts climbing: (1) Safety belt, boots, and gloves. (2) Two wrenches for *each* of the two bolt sizes on the tower. (A ratchet and socket help a lot.) (3) A drift punch and hammer. These are used to help align the bolt holes. (4) All of the nuts and bolts for all of the tower sections. (5) A small pulley which can be used to raise the gin-pole from one section of the tower to the next. (6) A work platform, if used.

Item six is not a requirement, but it can make the tower work a lot easier and save a lot of wear and tear on your feet and back. (See Photo G.) Once again, I wish to emphasize that very important point: If you can't relax while doing tower work, *stay on the ground*. There is no way

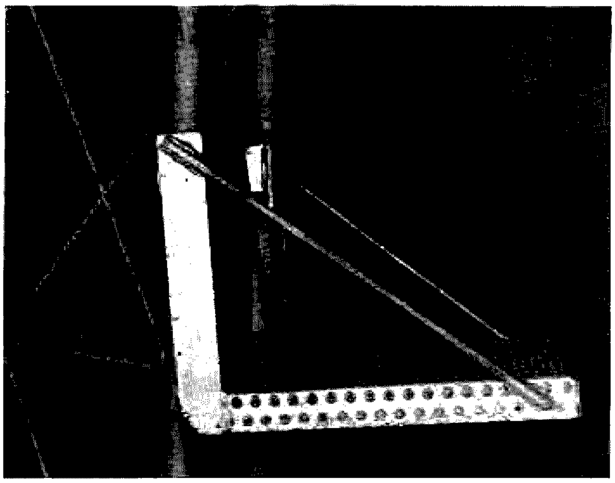

Photo G. A work platform can make tower erection much easier.

that you can hold on with one hand and work with the other. Tower work requires both hands and all of your attention.

Your first job is to place the gin-pole at the top of the first section. Carry the pole up the tower with the pole in the lowered position, or use the small pulley. Once you have it in place on the tower, you can raise the pole. Be sure to place the clamp on a tower leg so that sections can be pulled up without obstructions being in the way.

The clamp should be positioned so that it faces away from the tower. The pulley should be rotated so that it faces toward the inside of the tower. Do not use pliers to tighten any of the clamp screws on the gin-pole; hand-tight is sufficient on all three screws. Photo H shows a picture of the gin-pole clamped in place on the tower.

While you are mounting the gin-pole, your ground man should be tying the rope to the next section of the tower. The rope should be tied approximately two-thirds of the way up the section. If it is tied too high, you will have trouble placing the sections in place. Photo I shows how I tie the rope on. You will notice that this is a slip knot. Many people have looked at this and said, "It won't work." I have used this knot to send up over 500′ of tower sections and never has it come loose.

Once you have the third section of tower in place, the first set of guy lines should be attached. I personally recommend that if you put up thirty feet or more of tower, it should be guyed. The Rohn catalog gives recommended guying heights for various tower heights. While you are working on the third section of tower, have your ground man getting the guy lines ready. Each line should be prepared as shown in Photo J *before* it is sent up to you. The loop should be about three inches long, and two cable clamps (minimum) should be used at each loop.

When you have the gin-pole ready (you can do this before moving the pole if you want), have the loop sent up to you on the gin-pole line. Each line should be taken to the turnbuckle it attaches to and measured to length before cutting. The turnbuckles should be screwed to the maximum *out* position before measuring. *Do not* try to pull the guy line tight when you are measuring it, but leave plenty of slack. The lines can't be tightened until all three lines are attached.

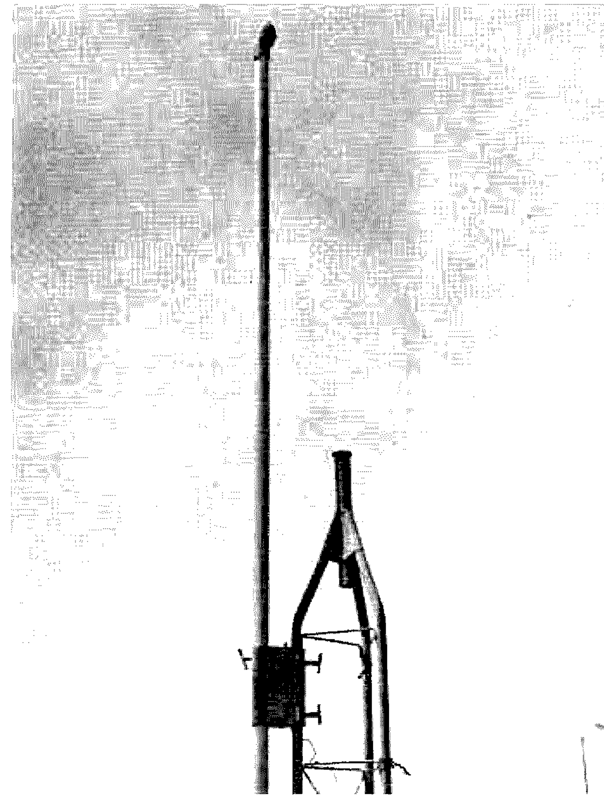

Photo H. The gin-pole is clamped in place at the top of the tower.

Leave a couple of feet extra so that the cable clamps can be fastened. When you cut the guy cable, be sure to tape both sides of the cut with electrical tape before you cut it. A small pair of bolt cutters does a good job of cutting the cable.

After the first line is attached, have the second one prepared and sent up. After all three guys are attached, the tower man should come down, because the next job is easiest when done by all hands—preferably with four men. Have one man on each of the guy lines, and the fourth man at the tower, with a two-foot or longer level. It is best to use a ladder, so that the level can be placed on the middle of the second section or higher (15′ from the ground).

The level man should not stand on or hold onto the tower when he is leveling it. Each turnbuckle should be tightened until the tower is level. Take at least two perpendicular readings (90° from each other) on each leg to ensure that the tower is level. The first set of guys is very important. If the tower is not properly leveled at this point, you may never get it straight.

If you turn the turnbuckle all the way in and still need more tightening, then back it all the way out, loosen the cable clamps, pull the cable until it is tight, re-clamp, and start tightening the turnbuckle again. When properly tightened, the guy lines still should have a fair amount of slack. You should be able to shake the cable and have a small amount of ripple in it.

If the cables are too

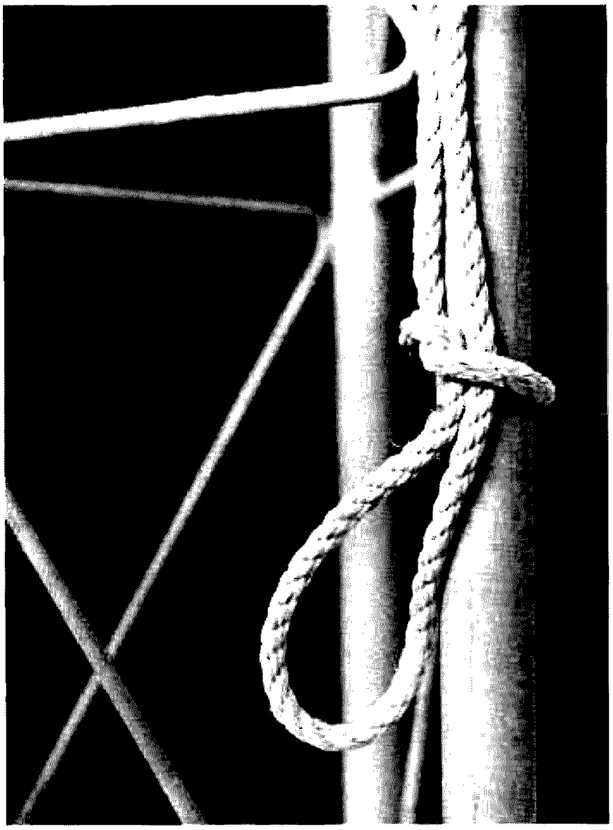

Photo I. A good knot to use when lifting tower sections.

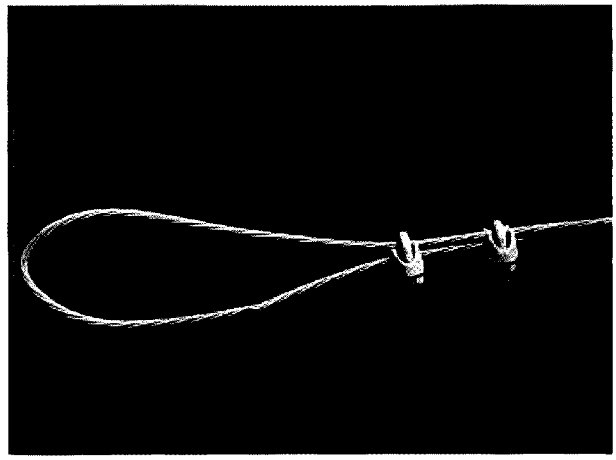

Photo J. The three-inch loop should be prepared before the guy line is lifted up to the tower.

tight, you stand a good chance of losing your tower. The theory is that of the reed in the wind. A reed will bend in the wind and not be broken, but a rigid plant will snap off because it is unable to give. A properly-guyed tower will have a small amount of sway to it. And remember that if you put up your tower in winter, you will need *less* slack than you would in the summer!

Continue to put additional sections of tower and guy lines on until the tower is completed. Additional sections of tower are leveled in the same manner. The only exception is that, rather than using a level, the level man should look up each leg of the tower. A section that is not level will stand out very noticeably. If you're not sure, have several people sight up the tower and level until the general consensus is that it is straight.

When all sections of tower have been installed and leveled, the turnbuckles should be safety-wired. This prevents movement of the lines from working the turnbuckles loose. The method I prefer to use is the "figure-8" safety wiring. This can be seen in Photo K.

Another feature you may want to add to your tower is a skirt on the bottom section. Remember, your tower is classified as an "attractive nuisance." The skirting I used can be seen in Photo L. The best way to make this is to take a section of tower to a local air conditioning contractor and ask him to make you a piece of metal 8' long to cover the tower. You can have him attach it to the tower, or do it yourself. The best way to attach it is to use pop rivets. Be sure to leave space at the top and bottom of the section so that the mounting bolts can be installed.

The only remaining part of the job is the antenna and feedline installation. Since there are so many types of antennas and mountings, I will not attempt to go into installation of them. If you intend to use a rotor, contact your Rohn dealer. He probably can fix you up with a rotor mount and thrust bearings that are made for the tower.

Two words of caution on feedlines: (1) There seems to be quite a bit of unjacketed Heliax® available that has been removed from commercial service. If you run across any of it, take it if it is given to you, proceed to your nearest scrap metal yard, and sell it for the value of the copper. Under no conditions do you want to use it on your tower. When you place two dissimilar metals together and place them in an electromagnetic field, you have created a fantastic TVI generator. This is the reason that it was removed from commercial service. And (2), watch for kinks in the outer shield. If it is kinked, there is a 98% chance that the cable is ruined. If you need a good attenuator, it is fine. However, most people find it to no advantage to have a 3-dB attenuator in their feedline.

If you are planning to buy a complete tower, you can buy a package that has the tower, guy lines, turnbuckles, equalizer plates, and cable clamps. This could save you some time and money. Check with your Rohn dealer about the package tower before you buy all the pieces individually.

Be sure that the tower you buy will handle the wind loading and weight for the antenna system that you plan to use. If you plan to use the pump-rod guying technique, be sure to order two extra equalizing plate kits. Also, check to see that there is sufficient guy line to meet your guying needs. The packages are set up for the ideal guying, but there is a very good chance that your installation will need more cable.

I hope that this article has given you some insight into the proper methods of erecting a tower. I claim neither to have covered every possible condition you may encounter nor that this is the only way to put up a tower. All I can say is that these are some of the most acceptable methods I've tried in 15

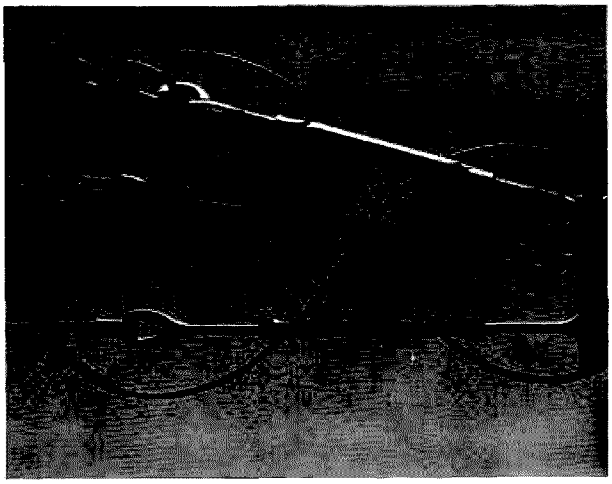

Photo K. A "figure-8" safety wiring for turnbuckles.

years of putting up ham and commercial towers.

If you have any suggestions or questions, I will be glad to respond to them. If you wish and expect a reply, send an SASE. Good luck, and remember the final words of Harry Splash, the tower rigger: "I knew that I should have replaced that worn strap on my safety belt!"

Note: Thanks to Deborah Coyle for proofreading and typing this article, and to Sue (WB7CXE's YL) for help with the photo work. ■

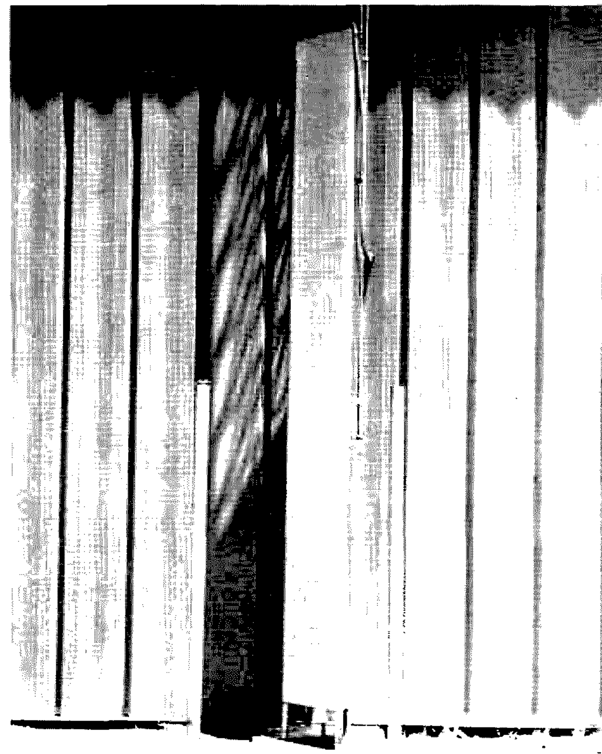

Photo L. A skirting at the bottom of the tower lessens the "attractiveness" of your "attractive nuisance."

The Revolutionary Organic Antenna

—product of NASA research

Arm yourself!

Author's Note: To prevent possible adverse heating effects in the arm tissue, it is important that power input to antenna described in this article be limited to 10 mW.

James C. Gaddie
Russell T. Wolfram
(SRI International)
Ames Research Center
Moffet Field CA 94035

A human arm may be made to act as an antenna for a communications system. It has been done by using an energy coupler made of two strips of copper foil fastened to a strap and wrapped around the wrist. Apparently, the wrist strap can efficiently transfer radio-frequency energy to or from the arm.

Reprinted from NASA Tech Briefs, Summer, 1978.

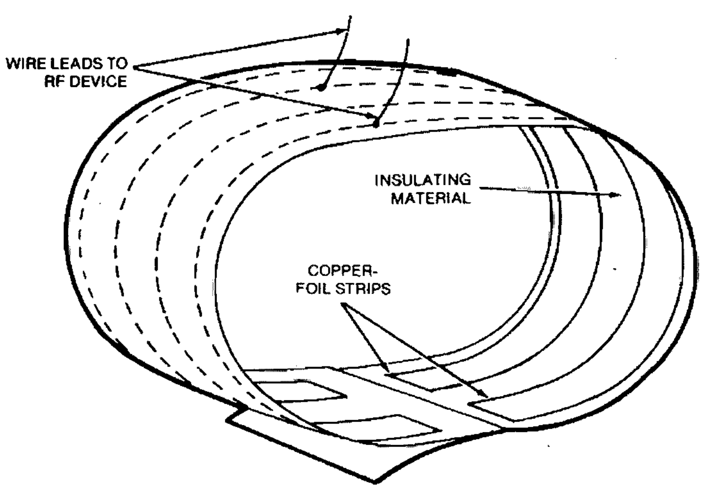

Fig. 1. Wrist-strap coupler of radio-frequency energy consists of two strips of copper fastened to an insulating material. Wires at the midpoints of the strips lead to the radio-frequency device that can act as a transmitter or receiver.

A prototype of the antenna coupler was built and found suitable for both sending and receiving very-high-frequency signals. The goal of the developers is to build a body-worn communications system for the deaf blind, and it was with this purpose in mind that the prototype unit was built and tested. Other potential applications for the compact coupler include body-worn two-way local communications systems for police and as part of a portable personal communications system that could communicate via satellite.

The copper-foil strips of the wrist-strap coupler shown in Fig. 1 are rectangular, 5 in. (13 cm) long and ½ in. (1.3 cm) wide. They are placed 7/16 in. (1.1 cm) apart and are fastened to the underside of a wrist strap made of an electrically insulating material. A thin insulating

strip is also placed over the straps as a protective cover. Such an insulator can be added to the wrist strap because the copper strips need not be in direct contact with the skin for the rf signals to be coupled to or from the arm.

For connecting the coupler to a transceiver, or receive- or transmit-only unit, a small wire is attached to the edge of each copper strip at a point equidistant from the ends of the strip. Each wire is then routed through a hole in the insulating material to the upper surface of the strap. In addition, a fastener must be attached to the strap so that it can be pulled snugly against the wrist.

Radio-frequency energy couples to or from the arm through the electrical capacity between the arm and the copper strips. Electrical impedance charac-

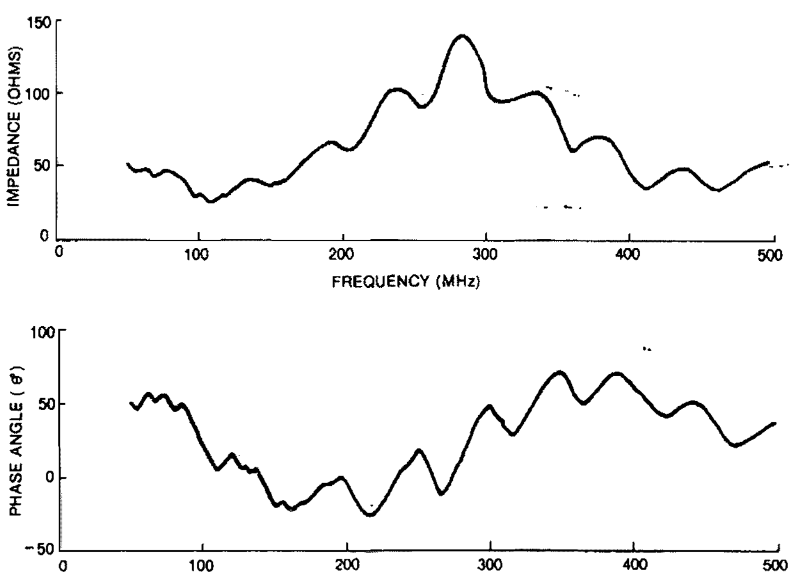

Fig. 2. Electrical impedance characteristics of the wrist-strap antenna coupler were measured with a General Radio 1710 rf network analyzer. Varying the widths of the copper strips will produce somewhat different characteristics.

teristics of the antenna are shown in Fig. 2. The radiated field strength, with the strap driven by a 170-MHz, 10-mW transmitter, was found to be slightly greater than that from a well-designed loop antenna built with a 16- by 11- by 3-mm ferrite core and driven by the same transmitter.■

DDRR Dipole for VHF

—experiment!

Seeking selectivity.

Dave Atkins W6VX
130 N. Westgate Ave.
Los Angeles CA 90049

Selectivity in an antenna is becoming increasingly important as the bands compress under the load of more and more stations. Reception is where this is most desirable. Front-end overload, we have learned, will cause big problems to a communications circuit when off-channel signals are strong. Directional-type antennas, of course, are the answer unless we need to cover everything around us. The DDRR, or directly driven ring radiator, developed by its inventor, J.M. Boyer (with patents assigned to Northrop), has high selectivity. Because of this, it also is a low-noise device. This makes two good reasons for its superior performance. (*73 Magazine* for August and September, 1976, goes into detail of its design and advantage. There have been many other articles written about it over the years.) Two drawbacks are noted when the chips are down. One is the size of the ground plane for the monopole design; the other is the cost of the conductor material for low-frequency use. Tuning can be another problem where its use for high-power transmission is contemplated. Very high voltage and current are the prices of the trade-off for high selectivity.

What Is It?

Boyer suggests the DDRR dipole in his September (part two) article. This version does without the big ground plane, as would any dipole. So here we have a quarter-wave open transmission line formed into a shape which "leaks" and radiates rf. I first built one of these for ten meters and made it so it operated on its highest frequency (no added capacitance) and at a fixed frequency. A/B checks with the spaced rings mounted vertically compared very well with those of a horizontal folded dipole at the same height and with the same orientation. Pretty good for an antenna on ten meters which is 30 cm "long" and 84 cm in diameter (see *73*, April, 1965, "Double Hula," Peter Lovelock).

The Two Meter DDRR Dipole

To make the two meter model, I dug out an old ¼-inch tubing coil from a long-forgotten final and annealed it in the fireplace, then cleaned and polished the surface after stretching it between a car bumper and a stout post. 33 inches comes to a half wave. This is then folded on a one-inch-diameter rod or mandrel at exact center. The quarter-wave line is formed on a can to make a circular double ring or transmission line of about 5 inches diameter. This will resonate above the 148 MHz end of the band. I made a simple tuning arrangement of a 4-inch piece of #20 (0.8 mm) Teflon™-covered flexible wire. This is formed into a U to slide into the open ends of the line. When

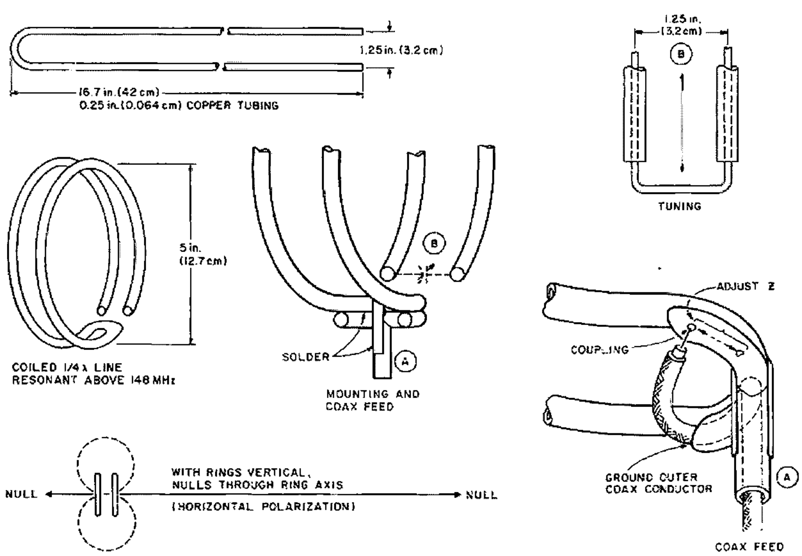

Fig. 1. Two meter DDRR dipole.

pushed in, the frequency should more than cover the 2 meter band. See detail B in Fig. 1.

A length of small-diameter coax may be coupled tightly to the closed end of the open line. Mine was fed through a separate matching U-shape of the same tubing soldered to the closed end of the line. A good match was obtained by varying the size of the link (see drawing). A 50-Ohm match comes at an area of less than that formed by the 180 degree half turn at the closed end of the line. The ¼-inch line thus formed needs no insulators for support.

Mounting of the completed antenna may be done in several ways. Mine was to make a pedestal a few inches long and to feed the coax through. This was mounted breadboard fashion on a piece of hardwood. A BNC coax connector was fastened to this piece. A tuning arrangement was made to slide the Teflon tuning U in or out to cover the band of interest. The selectivity curve was measured using a signal generator, a counter, and an FM receiver. The antenna frequency was left fixed and the receiver and generator were moved together across the antenna frequency.

While vertical polarization is the way most of our present two meter signals leave the antenna, things happen that make the polarization somewhat different at the receiving end. By orienting the receiving antenna, it is often possible to null out an interfering signal. By going a step further, I made the mounting adjustable in azimuth and elevation. This also can be done in various ways—mine is a breadboard way to test the idea. Aiming it works well and can reduce multipath *and* QRM.

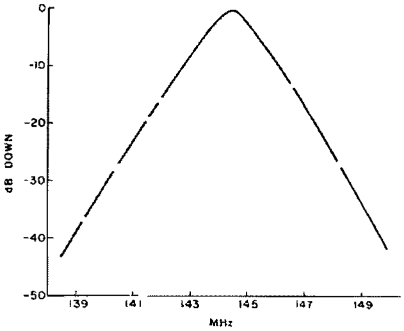

Fig. 2. Two meter DDRR dipole antenna selectivity.

Conclusions

While the amount of selectivity afforded by the DDRR will not come up to that of a multipole filter, it is worthwhile in that it is ahead of the front end—aiding in the signal-to-noise problem. An undesired signal off to one side is noise, too.

Do not try transmitting with the device with the tuning method described except with very low power. It will not pass the smoke test.

Broadband antennas are very convenient (discones, rhombics, and tribanders), but who needs all these unwanted signals going up and down the feedline? Phased DDRR elements could improve selectivity as well as gain.

A selective antenna should make a big difference to you. ■

Social Events

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

LOUISVILLE KY
JUN 29-JUL 1

The Louisville Area Computer Club will hold its 4th annual Computerfest™ 1979 from June 29 through July 1, 1979, at the Bluegrass Convention Center, Louisville, Kentucky. Activities include a flea market, seminars, and exposition, as well as activities for the entire family. Seminar and exposition admission is $4.00. Pre-registered Ramada Inn guests ($29.00, single; $34.00, double) receive free admission. For advance mail information, write Computerfest '79, Louisville Area Computer Club, PO Box 70355, Louisville KY 40270, or phone Tom Eubank, Chairman, at (502)-895-1230.

BATESVILLE AR
JUN 30-JUL 1

The Arkansas Army MARS meeting will be held on June 30-July 1, 1979, at the Independence County Fairgrounds, Batesville, Arkansas. There will be a fish fry on Saturday and a pancake breakfast on Sunday. Camping and motel rooms will be available. For further information, contact Robert Glines WB5KUI/ADN2MH, Box 97, Floral AR 72534, or phone (501)-345-2880.

BELLEFONTAINE OH
JUL 1

The Champaign Logan Amateur Radio Club, Inc., will hold its annual hamfest on Sunday, July 1, 1979, at the Logan County Fairgrounds, South Main Street and Lake Avenue, Bellefontaine, Ohio. There will be free admission and door prizes. Trunk and table sales are $1.00, and there will also be a bid table. Talk-in on 146.52. For more information, contact John L. Wentz W8HFK, Box 102, West Liberty OH 43357, or Frank Knull W8JS, 402 Lafayette Ave., Urbana OH 43078.

DUNKIRK NY
JUL 1

The Northwestern New York Repeater Association and the Northern Chautauqua Amateur Radio Club will hold their Lake Erie International Hamfest on Sunday, July 1, 1979, at the fairgrounds in Dunkirk, New York. A large flea market area and plenty of free parking will be provided. Tickets are $4.00 at the gate or $3.00 in advance. RV hookups are available. For information on advance sales or for a map showing easy directions from I-90, write to Dick Brinkerhoff WB2HEF, 123 5th St., Dunkirk NY 14048.

HARRISBURG PA
JUL 4

The Harrisburg RAC will hold its annual Firecracker Hamfest on Wednesday, July 4, 1979, at the Shellsville VFW picnic grounds, I-81 north, Exit #27 or #28, Racetrack Exit, Harrisburg, Pennsylvania. Look for the large balloon. Admission is $3.00, with no charge for tailgating. Tables will be available in the pavilion. Talk-in on .52/.52.

WELLINGTON OH
JUL 7

The Northern Ohio Amateur Radio Society will hold its second annual NOARSFEST on Saturday, July 7, 1979, at the Lorain County Fairgrounds, one mile west of Rte. 58 on Rte. 18, Wellington, Ohio. Admission tickets are $1.50 in advance and $2.00 at the gate and are good for all prize drawings. Children under 12 are admitted free. Gates open for the sellers and dealers at 6:00 am and to the public from 7:00 am to 5:00 pm. Indoor dealer tables are $4.00 each by advance registration. Drawing-only tickets are available by mail or at the gate for $1.00 each. Flea market spaces are $1.00 each. There will be over 100 prizes, including a Den-Tron HF-200 transceiver, a Ten-Tec 509, a DenTron GLA-1000, a Wilson Mark II, and an Optoelectronics counter. There will be plenty of food and free parking. Featured will be a large indoor exhibit hall for dealers and a huge blacktopped midway for flea market and trunk sales. There will be free camping outside the gates on Friday night, but no hookups. For advance registration, information, or tickets, write NOARSFEST, PO Box 354, Lorain OH 44052.

INDIANAPOLIS IN
JUL 8

The Indianapolis Amateur Radio Association will sponsor the Indianapolis Hamfest on Sunday, July 8, 1979, at the Marion County Fairgrounds, on the southeast corner of Indianapolis at the intersection of Interstates 74 and 465, Indianapolis, Indiana. There will be commercial exhibitors and dealer displays for a fee of $30.00 per booth. The commercial building will be open from 12:00 noon until 9:00 pm on Saturday and will reopen at 7:00 am on Sunday. Camper hookup facilities are available on the fairgrounds for overnight parking if you arrive on Saturday. A food and drink vendor will have a setup outside, while a professional caterer will have facilities inside. For more information, write to the Indianapolis Hamfest, PO Box 1002, Indianapolis IN 46206.

OAK CREEK WI
JUL 14

The South Milwaukee Amateur Radio Club will hold its annual Swapfest '79 on Saturday, July 14, 1979, at American Legion Post #434, 9327 S. Shepard Avenue, Oak Creek, Wisconsin. Admission is $2.00 and includes a happy hour with free beverages. Prizes include a $100 first prize, a $50 second prize, and a variety of other prizes. Activities will begin at 7:00 am and continue until 5:00 pm. Parking, a picnic area, hot and cold sandwiches, and liquid refreshments will be available on the grounds. Overnight camping is also available. Talk-in on 146.94. More details, including a map, may be obtained from the South Milwaukee Amateur Radio Club, Inc., Robert Kastelic WB9TIK, Secretary, PO Box 102, South Milwaukee WI 53172.

BEAVER PA
JUL 15

The Beaver Valley Amateur Radio Association will hold its 2nd annual hamfest on Sunday, July 15, 1979, from 9:00 am to 5:00 pm at Brady's Run Park on Rte. 51 west from Beaver, Pennsylvania. Shelters 12 and 17 will be used. There will be free space for vendors. Tickets are $3.00. Talk-in on .52 and directions on 146.25/.85. For information, write WB3FKE, 3414 47th Street, New Brighton PA 15066.

TERRE HAUTE IN
JUL 15

The 33rd annual WVARA Hamfest will be held on July 15, 1979, at the Vigo County Fairgrounds, one mile south of I-70 on US 41, Terre Haute, Indiana. Overnight camping will be available. There will be a free flea market, a covered flea market at $2.00 for a 12' x 12' space with some tables and ac available, XYL bingo, food, refreshments, and valuable prizes. Advance ticket sales are $1.50 or 4 for $5.00. Tickets at the gate are $2.00 or 3 for $5.00, with children under 12 free. Talk-in on .25/.85 and .52. For tickets and information, send an SASE to WVARA Hamfest, PO Box 81, Terre Haute IN 47808.

ALLENTOWN PA
JUL 15

The Delaware-Lehigh ARC, Inc., the BGYE, Inc., and the Lehigh Valley ARC, Inc., will hold their Tri-Club Hamfest on July 15, 1979, from 8:00 am to 4:00 pm at the Allentown Police Academy pistol range on Lehigh Parkway South at Allentown, Pennsylvania. Admission is $2.00 for lookers and $4.00 for sellers. Talk-in on .34/.94 and .52.

WILKES-BARRE PA
JUL 15

The Broadcasters Amateur Radio Club will hold its 2nd annual hamfest on July 15, 1979, from 9:00 am to 4:00 pm at Pocono Downs Racetrack, Rte. 315, four miles north of Wilkes-Barre, Pennsylvania. Setup begins at 8:00 am. Admission is $2.50, with no additional fee for sellers. XYLs and children are free. The event is all indoors. Talk-in on 147.66/.06 or 146.52. For more information, write John Soha W3KU, 62 S. Franklin Street, Wilkes-Barre PA 18707, or phone (717)-823-3101.

CANTON OH
JUL 15

The fifth annual Hall of Fame Hamfest will be held on Sunday, July 15, 1979, at Stark County Fairgrounds, Canton, Ohio. Tickets are $2.50 in advance and $3.00 at the gate. Mobile check-in on .19/.79 or .52/.52. For information, contact Max Lebold WA8SHP, 10877 Hazelview Ave., Alliance OH 44601.

GUANAJUATO MEX
JUL 19-21

The first annual ARARM-LMRE will be held in Guanajuato, Mexico, from July 19-21, 1979. Guanajuato is located 230 miles north of Mexico City. Registration will be US $13.00. A package will be available for US $40.00 and will include 2 banquets, 1 dinner dance, sight-seeing, theater, and gifts. Drawings will be held, with a grand prize being an SSTV setup. A total of 500 prizes will be given away. The US $40.00 includes registration. Hotels are available with prices ranging from US $10.00 and up for a double room. English-speaking guides are available from the University of Guanajuato. Talk-in on 147.63/.03, 146.10/.70, and 149.22/.82. HF/SSB frequencies will also be operating, and we

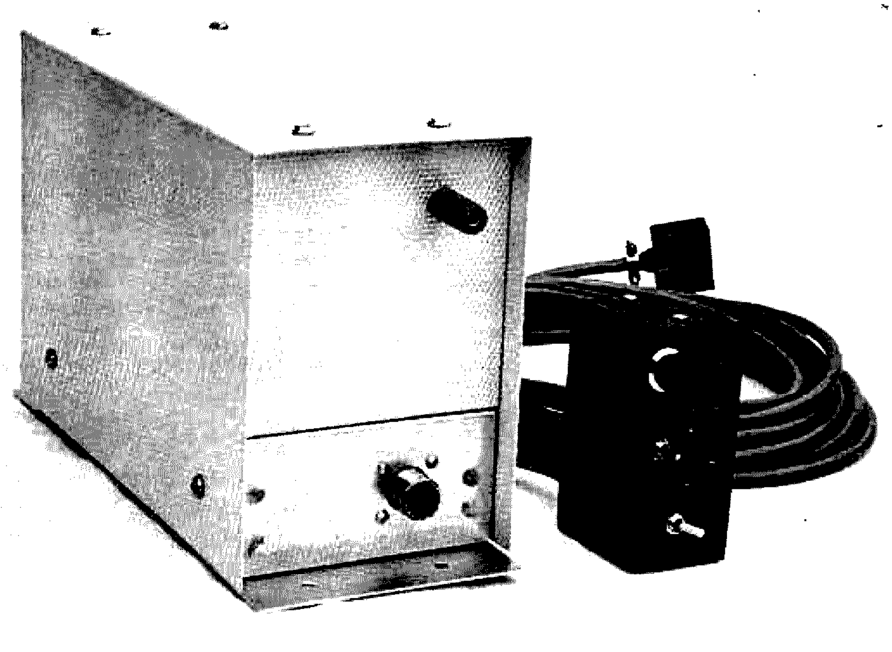
Tennamatic: An Auto-Tuning Mobile Antenna System

—works all of 40 and 75

Farewell to fading.

B. F. Brown W6TWW
1241 Arroyo Seco Dr.
Campbell CA 95008

Would you like to operate your mobile station over the entire 40 and 75 meter phone bands with a vswr not exceeding 1.15 to 1? With a Tennamatic, you can convert a high-Q narrow-bandwidth mobile antenna into a wide-bandwidth system. This means that you can use transceivers having solid-state finals and obtain full output power on any frequency in the 40 or 75 meter phone bands without any manual tuning operations. All you have to do is select frequency, start talking, and the Tennamatic will tune your mobile antenna system to resonance automatically, ensuring maximum field strength. Of course, if your transceiver has tubes in the final, you will still have to retune it when you QSY. Specifications for the Tennamatic are listed in Table 1.



The neat packaging of the Tennamatic can be duplicated easily. The control head, tuner cover, and end pieces are 0.040-inch soft aluminum cut in a paper cutter and folded in a vise using wood blocks. The chassis is described in the text.

History

About two years ago, I met Don Johnson W6AAQ, and I adopted his "big DK" mobile antenna system. He subsequently described it in his October, 1976, *73 Magazine* article entitled "Build a Weird 2 Band Mobile Antenna." His antenna neatly solved the problem of needing to change antenna loading coils when band-hopping between 40 and 75 meters. It also proved to be an exceptionally efficient radiator compared to the commercials, but it was still limited to only a few kHz of usable bandwidth on each band, and I wanted full band coverage.

To obtain full band coverage, I added a motor-driven roller inductor at

the base of the antenna and a control switch at the driver's seat, allowing me to QSY the antenna resonant frequency. This worked beautifully for about six months until I ran off a freeway one day while watching a field strength meter as I was peaking the antenna. Luckily, no damage was done, but the experience convinced me that for safety's sake I had to get out of the loop. This conclusion required me to design a servo system.

Design Requirements

I decided that the tuner would be required to tune automatically over all of the 40 and 75 meter phone bands and use easily-obtainable parts. The parts count was to be minimized to keep reliability high, complications associated with limit switches were to be avoided, and the power handling capability had to be at least 350 Watts PEP. It had to be easy to duplicate, present a pleasing appearance, and the control head had to be capable of being mounted on the side of an Atlas and be visually compatible. Last of all, the servo system had to be uniquely simple, have a 3- or 4-kHz deadband so it would not hunt or jitter around in the voice pass band, provide constant motor torque while tuning, and operate reliably over a plus ten-to-fifteen-volt supply voltage range.

The System

These design requirements led to a system consisting of two units. One unit is a control head and the other is the tuning unit. The tuning unit contains a phase detector and a servo system which drives a permanent-magnet dc gear motor. The motor turns a roller inductor taken from a surplus T21/ARC-5 or T22/ARC-5 command transmitter. The tuning unit also contains a toroidal impedance-matching transformer which ensures a good impedance match between the antenna and coaxial line. The control head has directional indicators, an automatic/manual operation switch, an automatic/manual indicator, a manual slewing switch, and an impedance-match selector switch. The units are shown in the photographs.

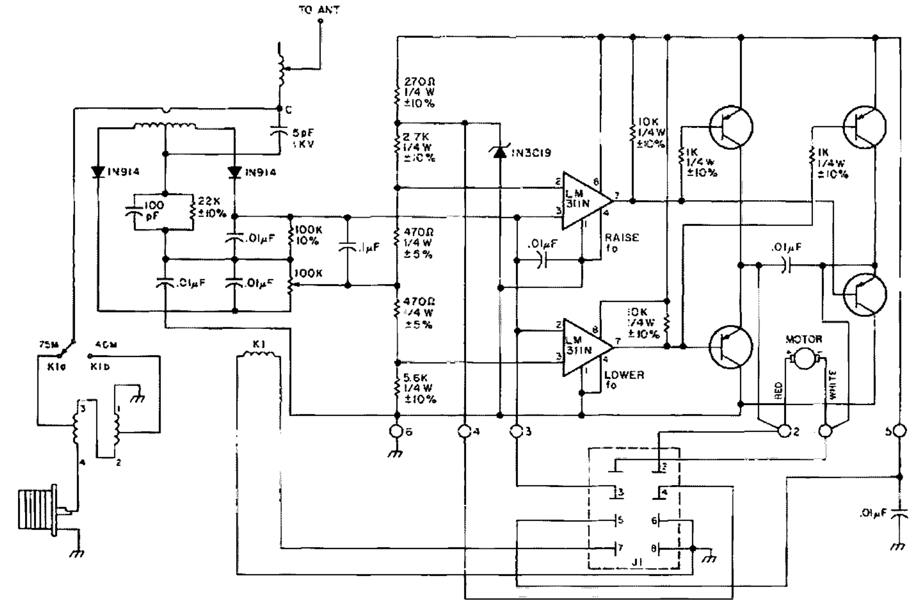


Fig. 1. Tuning unit schematic. The output transistors and motor are discussed in the text. The jack is a male chassis-type Jones plug.

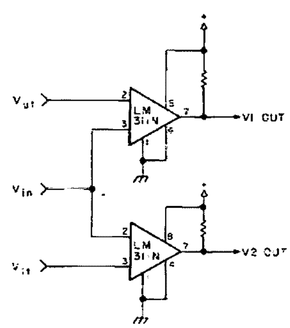
The Circuit

The circuit which I designed is depicted in Fig. 1. To understand its operation, it is best to start with an explanation of the servo system and work backwards toward the input. The system that I selected is known as a "bang bang" servo system in aerospace circles. It is either off or on in one direction of rotation or the other and provides full motor torque when on. Fig. 2 is a simplified diagram of the servo. It uses two LM311N voltage comparator integrated circuits connected as a window comparator. The circuit states listed in Fig. 2 simply say that if the input voltage (V_{in}) is a positive voltage between the upper and lower threshold voltages, the outputs of both comparators will be at supply voltage. If V_{in} either exceeds the upper threshold voltage or is less positive than the lower threshold voltage, one or the other comparator's output will be low. The low-state output is about one-half volt positive.

Referring back to Fig. 1, it will be seen that the comparator outputs are connected to diagonally-opposite transistors. When a comparator switches on and its output goes low, it turns on the associated transistors, resulting in one side of the motor being clamped to ground while the other side is clamped to the positive supply, turning the motor on. The upper comparator drives the motor in the direction which reduces inductance, raising the antenna system resonant frequency. The lower comparator drives the motor in the opposite direction, increasing inductance and lowering the antenna system resonant frequency.



Circuit states

$V_{in} < V_{ut}$: V1 out is high
$V_{in} > V_{lt}$: V2 out is high
$V_{in} > V_{ut}$: V1 out is low
$V_{in} < V_{lt}$: V2 out is low

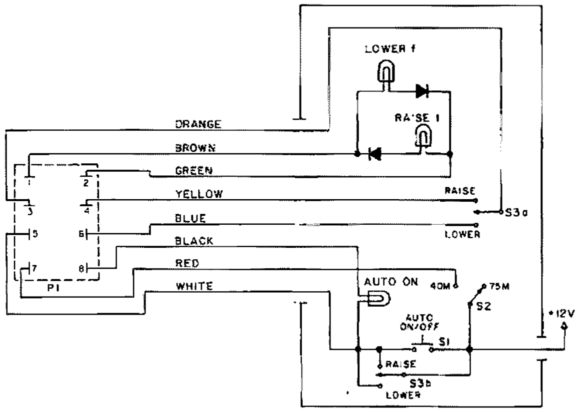

Fig. 4. The control head assembly connects to the Jones-type plug, P1, through 20 feet of TV rotator cable. The diodes are Radio Shack part number 276-1101.

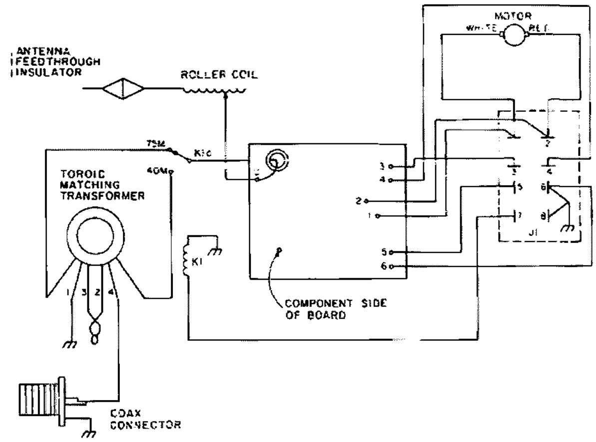

Fig. 5. Tuner unit wiring diagram.

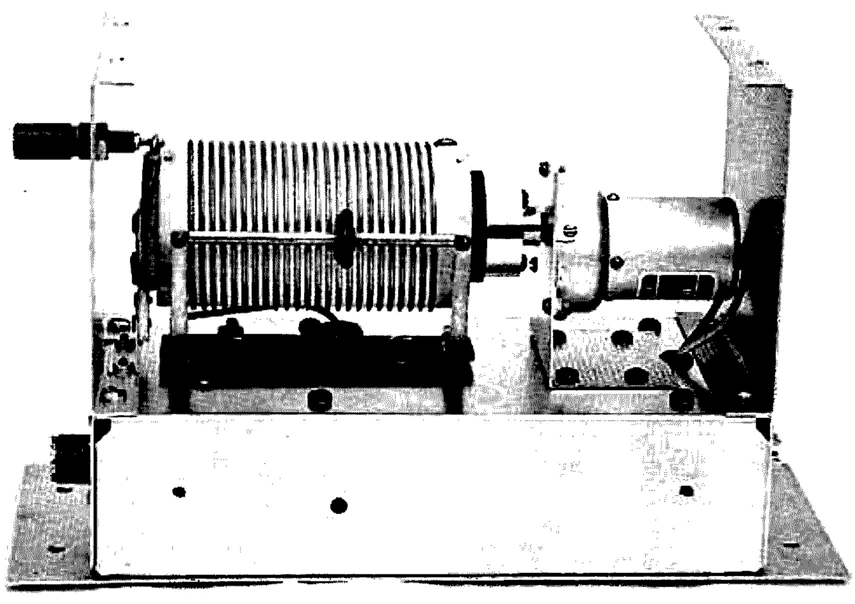
Fig. 3 shows the input circuit to the voltage comparators. The comparators must operate with their inputs positive with respect to ground, making it necessary to reference the phase detector to a point above ground. This reference point is the junction of the two 470-Ohm resistors. The output of the phase detector is connected to V_{in} and will be a voltage which will swing positive or negative with respect to the reference point, causing the comparator inputs to swing above V_{ut} or below V_{lt}, depending upon the off frequency condition existing at the time. The voltage divider is zener regulated to hold the switching thresholds constant. The voltage drops across the two 470-Ohm resistors set the width of the deadband to 3 kHz on 75 meters and 4 kHz on 40 meters.

The phase detector compares the phase relationship between the current flowing in the antenna circuit and the voltage from the antenna circuit to ground. When the input frequency is higher than the antenna system resonant frequency, the phase detector produces a dc output voltage across the two 100k load resistors which is positive with respect to the slider on the trimpot. Conversely, if the input frequency is lower than the antenna system resonant frequency, the output dc voltage is negative.

The trimpot is adjusted in operation to cause the phase detector to find exact resonance. It compensates for the inductive reactance inserted by the toroidal antenna impedance-matching transformer. The reduced output from the low side of the phase detector caused by the trimpot results in need for incremental downward QSY on 75 meters with pauses to allow the servo system to catch up. Even so, a QSY from 4000 kHz to 3800 kHz takes less than 30 seconds.

The impedance-matching transformer is necessary with the DK antenna because of its low input impedance at resonance. The taps are set at the 10-Ohm point for 40 meters and at the 14-Ohm point for 75 meters. These low input impedance values are excellent indicators of the low-loss characteristics and high performance of the antenna. Relay K1, a Potter and Brumfield KT11D 12 V dc 5-Ampere contact relay, selects the appropriate tap and is controlled by a manual switch on the control head.

Fig. 4 depicts the schematic of the control head. All of the switches, diodes, and 12 V dc indicator lamps are from Radio Shack. Switch S1 provides for switching the tuner into the automatic or manual mode and is a push-on/push-off switch. S3 provides capability to



Mounting details of the roller inductor, gear motor, and shaft coupler illustrate the mechanical simplicity of the unit.

manually slew the tuner up or down in frequency. It is a DPDT center-off-type switch. I have found that I use it rarely in operation, but it is nice to have in case you need it. It is needed during the installation adjustments. S2 operates the antenna-matching transformer tap-selector relay. No power on/off switch is provided, as power is taken directly from the transceiver. This prevents inadvertently leaving power on the tuner unless, of course, you forget to turn the transceiver off when you leave the car.

Construction

The photographs of the tuner reveal how simple the unit is to duplicate. It is built on a standard 2" × 4" × 8" aluminum chassis, and the motor bracket, end panels, cover, and bottom plate are easily constructed in the home workshop. Several W6s have built the tuner and made Plexiglas™ covers so that they can see the roller coil go into operation when they QSY. The layout I selected results in minimum antenna-circuit wire length and should be duplicated as closely as possible.

Don't get innovative by trying to reduce conductors in the control cable. You can quickly get into trouble because the voltage comparators are sensitive to rf and to ground loops and will go "ape" if you unknowingly build in a ground loop as a result of a circuitry change. Also, keep some spacing between the control cable and the coaxial line, as rf pickup in the control cable can lead to erratic operation. The wiring diagram is shown in Fig. 5. The only precaution here is to note the direction of the antenna wire as it goes through the hole in the toroidal phase-sensing transformer. If it goes through from the wrong side of the printed circuit board, the tuner will drive away from resonance.

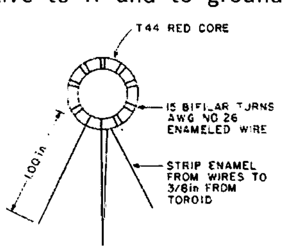


Fig. 7. Phase-detector transformer details. Note: Cut two wires 12" long and wind in parallel for bifilar winding. Connect the opposite ends together as shown for center tap.

Antenna-Matching Transformer

A T-106 red toroidal core, obtained from either G.R. Whitehouse or Amidon Associates, both of which advertise in several amateur magazines, is the heart of the transformer. Fig. 6 provides all necessary details for construction. The sleeve for securing the taps is a model airplane copper gas line obtained from a hobby shop and cut to length with a hacksaw. Should you desire to use an antenna other than the big DK, you must determine the antenna input impedance in Ohms at resonance with an antenna noise bridge and then determine the correct tap position from Table 2. If you don't use the DK, you will still have to change loading coils when changing bands.

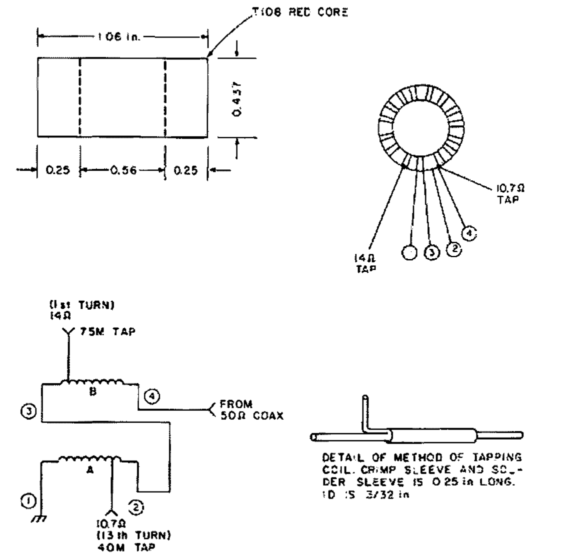

Fig. 6. Toroidal impedance-matching transformer details. Notes: Cut two wires 24" long and wind in parallel for a bifilar winding. Each winding is to have 14 turns. Taps and wires 1 and 4 are to be 2" long. Wires 2 and 3 are to be twisted and soldered and not to exceed ½" long. All wire should be AWG #18 enamel. Dip it in General Cement Red Glypt and hang up to dry before use.

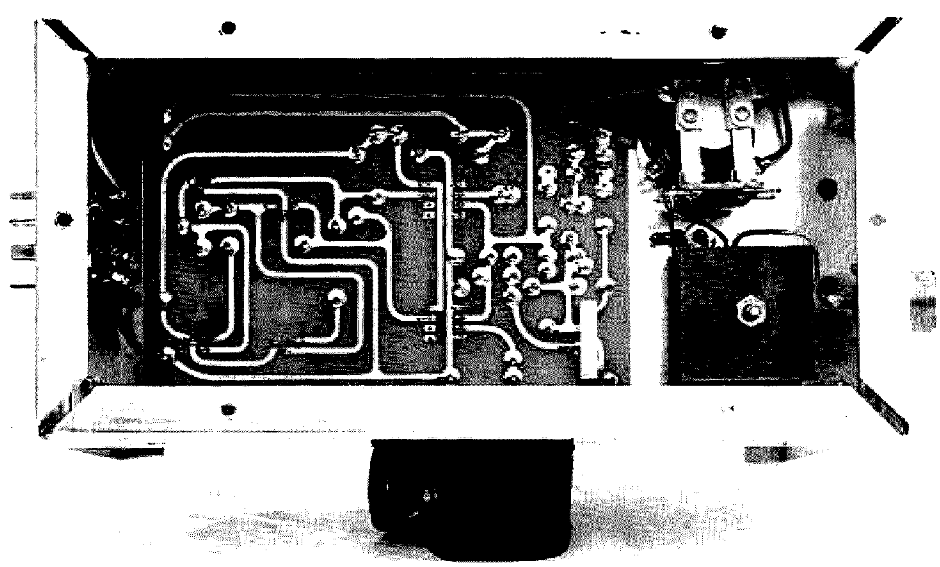
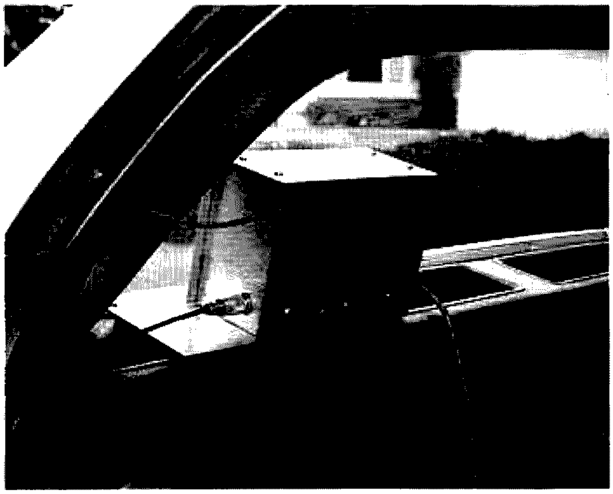
Phase-Detector Transformer

Construction details of this transformer are depicted in Fig. 7. When winding the transformer, be sure that the wires remain parallel to each other without any crossovers. Also, count each pass through the hole as a turn.



The under chassis view further illustrates the mechanical as well as the electrical simplicity of the unit. The toroidal antenna impedance-matching transformer is hidden by the masonite clamping pieces. The prop under the chassis is a photographic lens case.



This neat installation of the tuning unit in the left rear window of my station wagon permits a short lead-in from the ball mount outside.

Remember that it is impossible to wind a half turn on a toroid. This transformer need not be dipped in General Cement Red Glypt, although you may do so if you wish.

Gear Motor

The gear motor which I used and recommend is a Magna-Torc™ permanent-magnet 24 V dc motor with a type B gear reduction unit. Operated in the Tennamatic, this motor will turn the roller inductor at approximately one revolution per second. The motor is manufactured by the Hansen Manufacturing Co., Princeton, Indiana 47670. It may also be obtained from Hartfield, Kennan, and Freytag, PO Box 328, Fremont CA 94536. The motor is expensive at about $21.50 per copy; however, it is the smallest and neatest solution to the drive-motor problem and well worth it.

Others who have built this tuner have found various surplus motors or used window crank-up motors obtained from auto wrecking yards. These high-current motors are quite bulky, do not allow neat packaging of the system, and also require the addition of relays to the output of the tuner, since the transistors can not drive them directly. These surplus motors do have the advantage of being cheap, however.

Shaft Coupler

The shaft coupler mates the gear motor drive shaft to the thumbwheel on the end of the roller inductor. It is made of aluminum turned out on a lathe and is simply bolted with three 6-32 machine screws to the thumbwheel. Fig. 8 provides the dimensional details. One of the photographs shows how it looks when the motor and roller coil are coupled together.

Frequency range:	75m—200 kHz 40m—300 kHz
*Slewing rate:	75m—6 kHz/sec. 40m—40 kHz/sec.
Minimum Δf:	75m—requires 3 kHz QSY to activate tuner 40m—requires 4 kHz QSY to activate tuner
Maximum Δf:	75m—50 kHz (QSY of 200 kHz in four increments of 50 kHz requires less than 30 seconds.) 40m—200 kHz (QSY of 200 kHz requires less than 5 seconds.)
Vswr:	typically 1.15 to 1 or better after tuning completed
Modes:	automatic/manual
Input voltage:	10 to 15 V dc, negative ground
Input current:	420 mA at 13.8 V dc while tuning; 125 mA at 13.8 V dc after tuning completed
Power rating:	350 Watts PEP

*Table 1. Tennamatic specifications. *Full carrier inserted. On SSB, the slewing rate is slightly slower due to speech pauses.*

Printed Circuit Board

Fig. 9 depicts the printed circuit board. Be sure that you watch the polarity of the phase-detector diodes when you insert them. Also, it is a very good idea to use integrated circuit sockets instead of soldering the integrated circuits directly into the board. The four output transistors can be Poly Paks green-body PNP power-tab transistors, part number 92CU2227, or Radio Shack PNP power-tab transistors, part number 276-1641. Both types are rated at 35 Watts with suitable heat sinking. Heat sinking is not required in this application.

If you use the Poly Paks transistors, bend the tabs at right angles to the body of the transistors to ensure that they clear other components mounted on the board. Make the bend about a quarter inch from the body of the transistor. Test them carefully for leakage before you solder them because I have found that about 25% of them are too leaky to work properly in this circuit. They will cause the directional indicator lights to light even when the system is at resonance. I've had no trouble with Radio Shack transistors.

The photograph of the underside of the chassis shows the printed circuit board as installed in the tuner. The trimpot was mounted on the foil side of the board because, when three-quarter-inch stand-

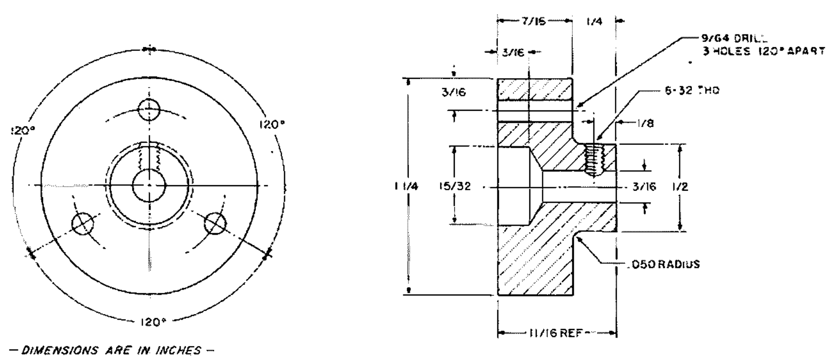


Fig. 8. Shaft coupler.

offs for supporting the board are used, the screwdriver access hole in the side of the chassis falls midway in the side.

I have a few extra printed circuit boards available at $5.00 each for those who prefer not to make their own.

Installation

Mount the tuning unit as close as possible to the base of your antenna. Connect the base of the antenna to the tuning unit with insulated AWG #12 or #14 wire. Do not under any circumstances use coax to connect the antenna to the tuner! Make sure that you ground the tuning unit to the car body by means of sheet metal screws or a short bonding strap. Use 50-Ohm coaxial cable to connect the tuning unit to your transceiver. RG-58A/U is satisfactory, and the length is not critical.

One photograph shows how I mounted the tuner in my station wagon. After mounting the control head to the transceiver (I used Velcro® fastening tape), connect the control head power lead to the transceiver so that the transceiver power switch will control application of power to your Tennamatic.

DK Antenna Adjustment

After installation of your Tennamatic, your DK antenna (or other antenna) must be retuned to be resonant on approximately 4025 and 7325 kHz. For this adjustment, the roller inductor must be slewed to minimum inductance using the manual slewing switch. Next, you must determine the antenna resonant frequency on both 75 and 40 meters using your vswr bridge or field-strength meter. Resonance will be lower than it was before the Tennamatic was installed. Don't overlook changing the impedance-matching tap when you change bands looking for resonance.

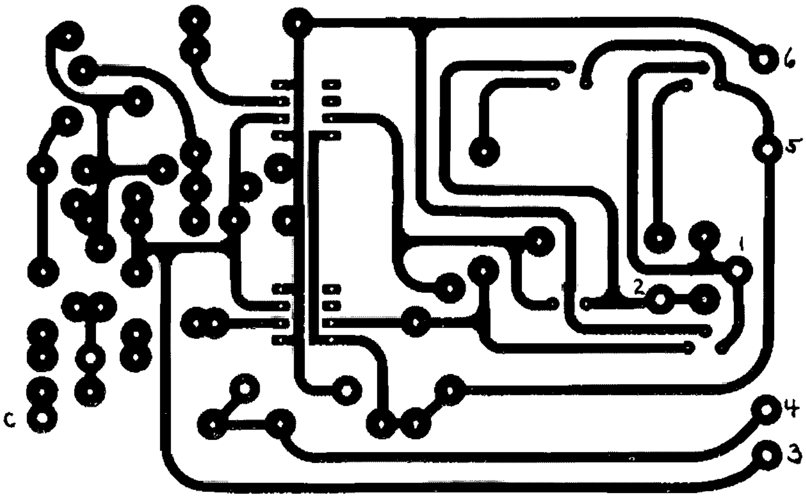

Fig. 9(a). PC board.

Now that you know where the antenna system resonances are, you can proceed to raise them by removing turns from the loading coil, shortening the whips, or by a combination of both methods. If the two resonances are as low as 3900 kHz and 7150 kHz approximately, you may find it better to remove a turn or two from the bottom of the loading coil and one or more turns from the top of the loading coil in order to minimize the amount that must be trimmed off the whips. Remove turns only one at a time. Be sure to check the resonant frequency on each band after each adjustment because they interact, and it is essential that you do not go too far. By the time resonance is approaching the upper band edge on 75 and 40 meters, you should have determined the number of kHz per inch of frequency change you get with each inch cut off. The kHz-per-inch figure will be different for each whip. After reaching 3995 kHz and 7295 kHz, cut off an additional increment from each whip determined by dividing 30 kHz by the number of kHz per inch for each band. This will complete the antenna tuning procedure.

Tuner Trimpot Adjustment

This adjustment is made to cause the tuner to tune for maximum field strength (coincident with minimum vswr). When adjusted on 40 meters, it will also be correct on 75 meters. Adjust as follows:

1. Make sure your vehicle is at least fifteen feet away from other vehicles, trees, buildings, or metallic objects.
2. Turn the trimpot fully counterclockwise, and

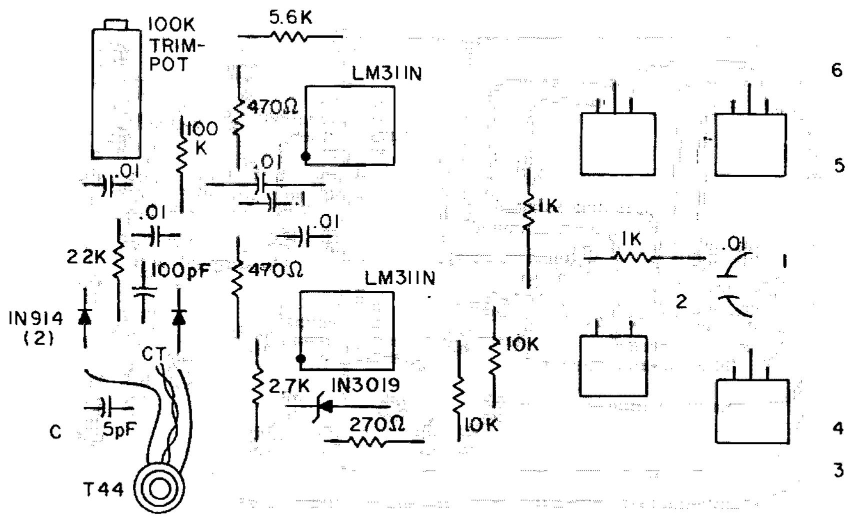

Fig. 9(b). Component locations viewed through the foil side of the board. When installing the LM311N integrated circuits, line up the dot on the IC with the dot shown on the outline of the board. The T-44 phase-sensing transformer may be glued to the board. The four output transistors are mounted against the board.

Table 2. Transformer taps required for various antenna input impedances to match 50-Ohm coaxial line.

then preset it six turns clockwise.

3.Turn on your transceiver. Place it in the tune mode with carrier inserted on the 40 meter band.

4. While watching a field-strength meter or vswr indicator, tweak the trimpot until you observe maximum field strength or minimum vswr. The Tennamatic must be in the automatic mode for this adjustment. Your unit is now ready to operate.

Operating Results

With a year and a half of operating experience, the Tennamatic has demonstrated that high-Q mobile antennas are extremely sensitive to the environment around them. For example, a dense fog will lower the antenna system resonant frequency on 75 meters by as much as 25 kHz, but the Tennamatic will compensate by rolling the inductor to less inductance. I leave it in the automatic mode at all times while driving, and, as long as I am talking, it will compensate quickly for the detuning caused by passing trucks, cars, trees, freeway overpasses, bridges, and residential power line drops as you drive under them. The result is that most of the characteristic mobile fade, which I now realize is due to antenna detuning, is eliminated. The result is such a strong steady mobile signal that I frequently have to convince my contact that I am really mobile!

There is one thing that the Tennamatic cannot compensate for. That is another 75 or 40 meter mobile parked up to twenty feet away. The mutual coupling between antennas, reflected signal, and phase shifts cause it to go "ape." So, if you build one, don't proudly try to demonstrate it when parked near another mobile.

Acknowledgement

I would like to acknowledge with my thanks the numerous suggestions made by Don Johnson W6AAQ as this project proceeded through the breadboard, prototype, final design, and evaluation phases. I also wish to express my grateful appreciation for the photography provided by Jerry Fulstone WA6EJV. ■

Add Solid-State Braking to the T²X

—a worthwhile improvement

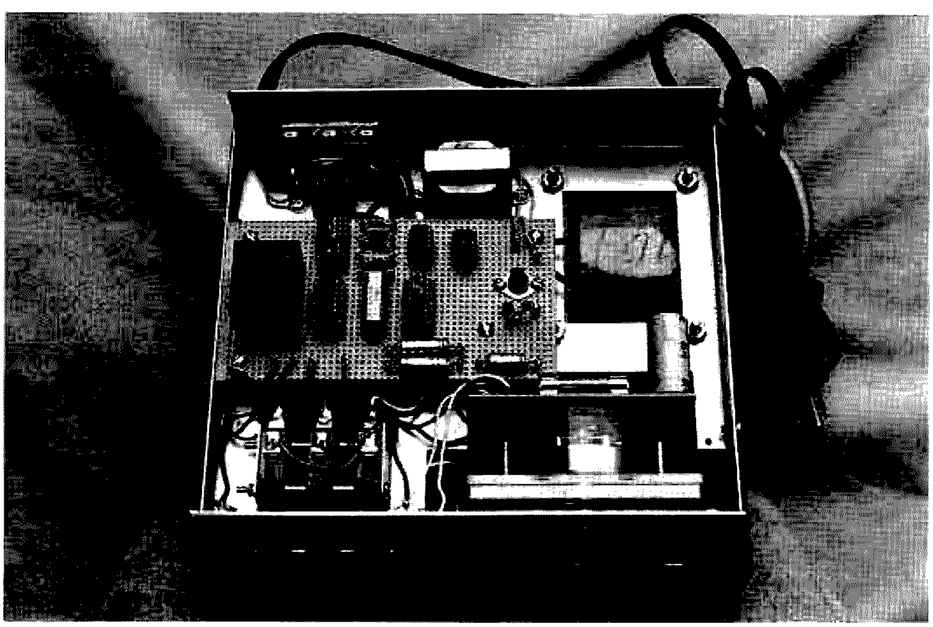
Tame your Tailtwister.

The T²X "Tailtwister" rotor by CDE is quite a piece of machinery. It's a heavy-duty rotor capable of turning an antenna system with 26 square feet of wind load, has a coast-down pre-brake action, and has a wedge brake system that keeps the rotor from slipping when not in use. As an added safety feature, power is not delivered to the directional controls until the wedge brake has been released.

In order to get the rotor to turn, you must press the brake release switch on the control unit, holding it down while pressing either the clockwise or counterclockwise direction switch. Once the antenna reaches its destination, the direction switch must be released first, followed by the brake release switch after the antenna has coasted to a stop. If you should let go of the brake release switch before releasing the direction switch, or if both switches are released simultaneously, the wedge brake will immediately engage, bringing the system to an abrupt stop, placing undue strain on the rotor, mast, antenna system, and the tower itself.

Holding onto the brake release switch until the rotor has had plenty of time to coast to a stop is much easier in theory than in actual practice. What this means is that sooner or later you could have troubles, unless you can guarantee that the wedge brake won't be constantly slamming into the gears of a moving rotor.

One solution to this problem is to electronically delay the engagement of the wedge brake for a small period of time after the rotor has stopped turning. The circuit I designed to accomplish this consists of four ICs, one optoisolator, a small power supply, and a solid state relay. All the parts, with the exception of the power transformer, filter capacitor, and bridge rectifier, are mounted on a 5¼" x 2¾" perfboard using standard wire-wrapping techniques. The entire circuit fits in the rotor control unit, and no modifications to either the rotor or the outside appearance of the control unit are required.



The power to the rotor's brake solenoid and directional circuitry is switched by a Grayhill Solid State Relay, which takes the place of the brake release switch in the original schematic—see Figs. 1(a) and 1(b). The SSR is ideal for this application for a number of reasons:

1. Its zero voltage turn-on and zero current turn-off characteristics plus its 3000-volt-per-microsecond transient protection allow it to switch a 110-V-ac inductive load at 4 Amps without the contact arcing found in a mechanical relay.
2. It will switch with 5 V dc of control voltage and draw less than 5 mA of current, making it compatible with TTL.
3. It physically separates

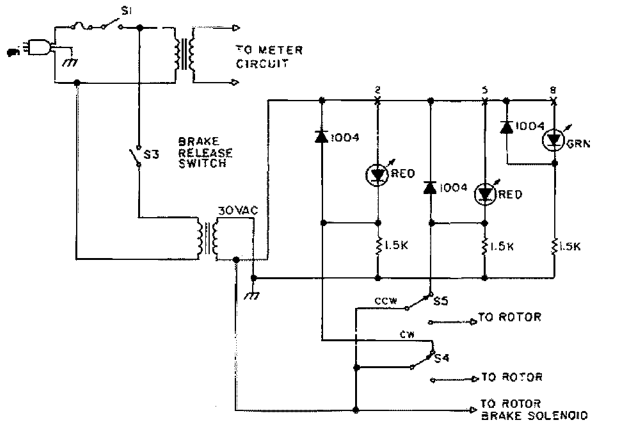


Fig. 1(a). Detail of control unit (original version). All resistors ¼ Watt. "X" denotes wiring connection to the control unit PC board.

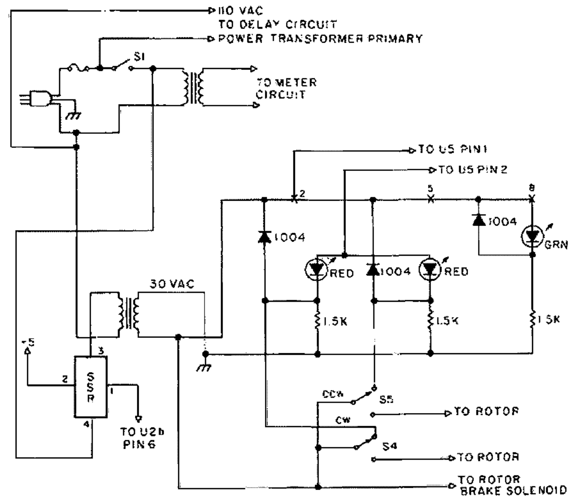

Fig. 1(b). Detail of control unit (modified version). All resistors ¼ Watt. "X" denotes wiring connection to the control unit PC board.

the digital control circuitry from the load by means of optoisolation, protecting the logic from any spikes that might be generated by the brake solenoid.

4. Its small size (1 cubic inch) enables it to be mounted directly on the perfboard, producing a very compact modification in the rotor control unit.

The rest of the circuitry on the perfboard (Fig. 2) determines the amount of time the SSR will remain energized. When the brake release switch (S_3) on the front panel is closed, the reset (pin 4) on the NE555 timer goes low, as does pin 6 on the 7409, turning on the SSR, releasing the wedge brake, and applying power to the rotor's directional controls. When the switch is released, the 74121 (which is triggered on the negative-going edge of its input pulse) applies a one-shot to the NE555, which in turn goes high at its output. This keeps pin 6 of the 7409 low, allowing the SSR to remain energized for approximately five more seconds. The five-second delay is determined by the RC combination of the 3.3-megohm resistor and the 1-uF capacitor on the NE555 and can be lengthened or shortened by increasing or decreasing the values of these components.

The input to the digitial circuitry is physically separated from the rotor's direction control voltage by an optoisolator (U_5) whose diode is wired in series with the LED directional indicators on the control unit—see Fig. 1(b). By the way, the optoisolator drops the total current in each directional LED by only 1 mA and therefore does not affect the original brightness of the indicators. If either one of the rotor's directional controls is pressed while the wedge brake is released, current will flow through the diode of the optoisolator. This causes the output of the optoisolator to go low (Fig. 2), resetting the NE555 and keeping the SSR energized. Releasing the directional switch triggers the 74121 which pulses the NE555 and holds the SSR on for another five seconds. As a result, it is no longer necessary to hold down the brake release switch once the circuit has been energized. The wedge brake will not engage unless all three front panel switches have remained open for five seconds. Closing any one of the switches during the five-second delay resets the timer and repeats the cycle upon release of the switch.

In building this circuit, I used a 1k resistor network in place of mounting separate pull-up resistors, but there is room to mount the ¼-Watt resistors separately on the perfboard if you don't have a network handy. It should be noted also that I have connected the primary of the digital logic power supply transformer—Fig. 1(b)—before the rotor control unit "Off/On Switch" (S_1) so that power is supplied to the ICs continuously. Although you might prefer to make the connection after the switch, this will tend to energize the brake solenoid as soon as power is applied to the box. Powering the ICs constantly (the digital logic draws considerably less than 100 mA) not only prevents this,

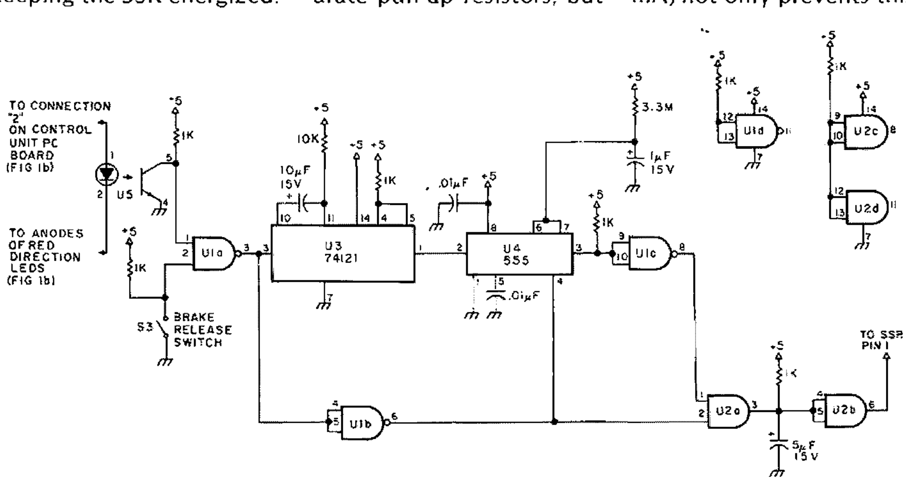

Fig. 2. Delay circuit. All resistors ¼ Watt. All capacitors measured in uF.

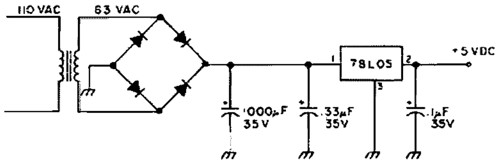

Fig. 3. Power supply.

but also is better for the ICs in the long run since they are not subjected to surges that accompany the application of voltage to the unit.

When connecting the wire-wrap wire to the SSR "control" pins, use the wire-wrap tool to make the connection, but make sure you solder the wire to the pins. Normally, solder is not necessary with the wire-wrapping technique, but the pins on the relay are round as opposed to the square wire-wrap pins, so solder should be used to ensure a solid connection.

Since all of the circuitry, with the exception of the power transformer, bridge rectifier, and 1000-uF filter capacitor (Fig. 3), is built on the perfboard, the digital logic can be checked for any wiring errors before connecting it to, or mounting it in, the rotor control unit. The 78L05 voltage regulator will handle up to 35 volts on its input (although it runs much cooler with the 6.3-volt supply used in this project) so you can temporarily power the perfboard with the output of a standard 12-V-dc supply. Attach a logic probe or voltmeter to pin 6 of the 7409 (since the 7409 has an open collector output, pin 6 must be connected to pin 1 of the SSR and pin 2 on the SSR must be connected to +5 V dc in order to get the proper readings). You should get a high-level logic state on the probe or a little under 5 volts on the voltmeter. Grounding pin 1 or pin 2 on the 7400 should change the reading to a low-level logic state (under 1 volt on the voltmeter). When you remove the ground, the reading should stay low for about 5½ seconds before returning to its original state.

If the circuit checks out correctly, disconnect the leads on the brake release switch (S_3) and solder them to the "load" pins on the SSR. Now you can mount the board on the bottom side of the control unit's chassis and hook up the power supply as shown in the schematics in Figs. 1(b) and 3. Connect a lead from one contact on the brake release switch to pin 2 of the 7400 and a lead from the other contact to ground. Unsolder the leads from connection points 2 and 5 on the control unit's printed circuit board (the board is numbered) and connect them both to pin 2 (the cathode) on the optoisolator (U_5). Connect a lead from pin 1 on the optoisolator (U_5) to connection point 2 on the printed-circuit board. Connection point 5 is not used. This completes the modification of the rotor control unit.

Although I made this modification on the Tailtwister rotor, the schematic for the control unit is very similar to the schematic of the Ham II and Ham III rotors. I have not modified these rotors, but this circuit should work with them and is worth checking into. The only real difference between the Ham II/Ham III schematics and the Tailtwister schematic is that the Tailtwister has the three front panel LEDs (two red ones for direction indication and one green one for an indication that the wedge brake has been released). These could be added quite simply if desired—see Figs. 1(a) and 1(b)—using three 1.5k ¼-Watt resistors and three HEP1004 (1N34A-type) diodes. Although the direction indicators are not really necessary, the brake release LED does indicate the status of the wedge brake and I would recommend that you install it if you plan to use the brake delay circuit. It should be a simple matter to mount the extra components on the perfboard.

In all, the addition of an electronic brake delav circuit makes a good rotor better and may save you from the headache of rotor troubles at a later date. ■

Parts List

ICs

1 SN7400 (U_1)
1 SN7409 (U_2)
1 SN74121 (U_3)
1 NE555 (U_4)
1 IL 1 or equiv. optoisolator (U_5)
1 uA78L05 5-volt voltage regulator

Resistors

7 1k, ¼-Watt, 10%
1 10k, ¼-Watt, 10%
1 3.3 megohm, ¼-Watt, 10%

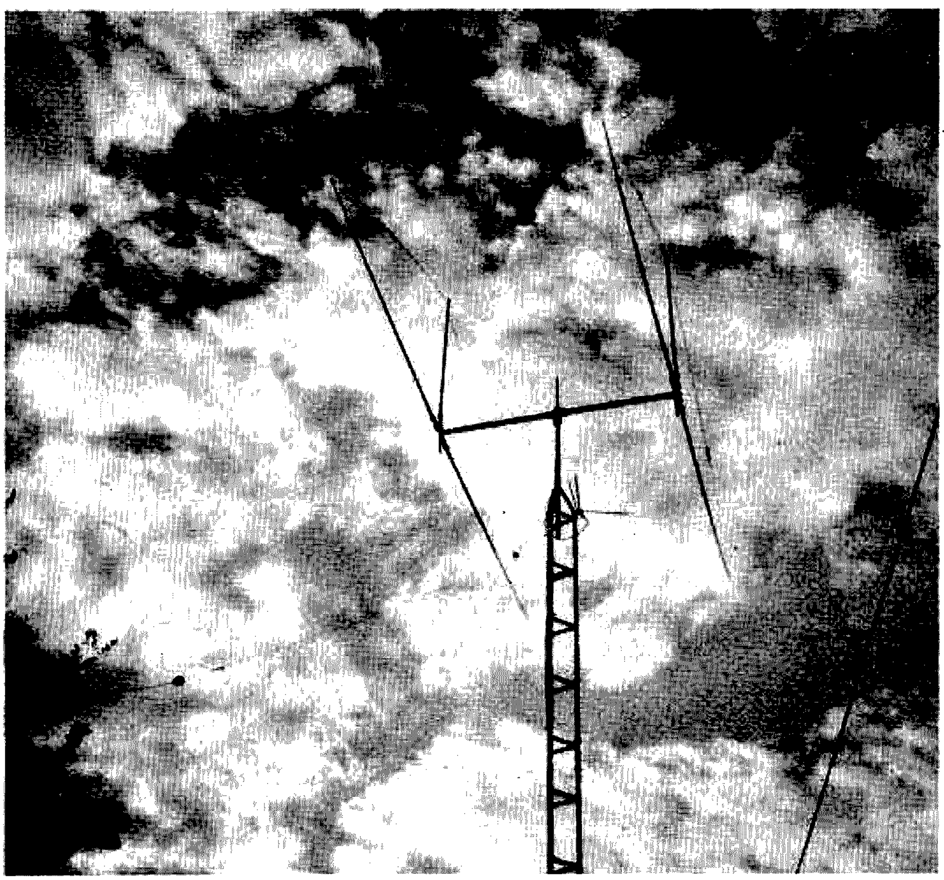
Compact Beams for 20 or 15
—build these when your quad bites the dust

Light, neat, rugged.



Jerrold A. Swank W8HXR
657 Willabar Drive
Washington Court House
OH 43160

My tower is just 11 feet from my neighbor's property line. The further I stay away from his television antenna, the better, lest I cause him TVI. I, therefore, have long wanted a 20 meter beam that, while a monobander, would not have a spread so long as to go outside my yard.

I do not like the regular 20 meter quad, as it is too big and floppy and somewhat unsightly, besides being easily damaged by the wind. I did not want to buy a triband beam, since I cannot operate 15 or 10 meters. I have only a three-band rig.

At one time, I had a 15 meter quad up for a couple

of years, and it worked fine, but since I cannot now work 15, I wanted to make a 20 meter beam out of my quad.

Everyone told me that this plan would not work, including one nationally-known antenna expert on quads. They said that bending back the ends of the elements would make it act like a transmission line.

I could have used loading coils, but most of all I did not want to have to buy an expensive beam. I had my quad put away and also had some parts of quad arms from another quad which I had once cut from 20 to 15 in my DX days. It was heavier, but a fellow ham had cut it down to 6½ feet to make a CB quad. Three of the arms had been broken when it fell while being taken down after he became a ham.

I decided to telescope one arm into a larger arm, and found that this would give me 11 feet per arm. I put epoxy on the smaller arms, or spreaders, and put them together. I was thus able to make four good arms and still have two usable short spreaders 6¼ feet long, by inserting aluminum tubing in one of the best broken arms. The 15 meter spreaders were still a full 8 feet long.

The reason I am telling you all of this is to make you think about ways of getting material for your beam. It would be possible to use bamboo or even wooden arms. If the arms are not hollow, you could tape the wire to the wooden arms. I actually tried this at first with the arms I am using, and then decided to see if the proximity of the aluminum spider would change the tuning of the beam elements. I found that it made no difference, so I removed the taped wires and fed the wires through the center of the fiberglass tubing.

I might mention a few booby traps I found as I went along. The first was that the stored tubing had been stopped up by insects and egg sacs. I used a 5/8 λ two meter mobile whip with the ball removed to poke out some of the debris. I then put my mouth to the small end, holding fingers over the hole which had been cut for wire in the old quad, and blew.

This worked with one arm, but not with two others. I tried poking wire through, but the wire was not stiff enough. I finally banged the large end on the concrete floor of my patio, and finally 8 cocoons fell out. I know now that I should have cleaned out the 15 meter quad arms before putting the two arms together. It would have been easier to handle them.

I then tried to push some #14 stranded wire through, but it kept catching on the end of the smaller inside arm. I took some #18 tinned wire and poked it through from the small end of the tubing, and it didn't buckle as it did when trying to force it the other way. I ran it through, twisted the end to the #14 Belden 8000, and pulled it back through.

I put a length of nylon tubing over the wire to keep it from being shorted to the bolts which held the clamps on the fiberglass arms.

I had cut the wire by formula to 16½ feet for the 14,200 MHz. I thus had 5½ feet left after reaching the end of the 11-foot arm. This I had to bend back. I put one of the short arms into the spider after placing the other 11-foot arm in the clamps. This I used in the upper arm of the spider. The lower arm of the spider was not used.

I could have left the upper arm unused and put the 6½-foot arm in the downward position. This I

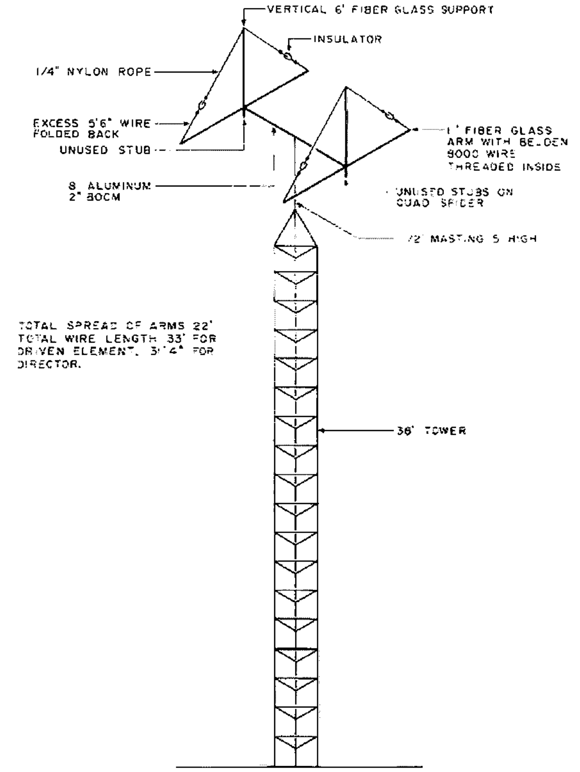


Fig. 1. Small light 20 meter beam.

decided against for two reasons. It would have brought the 5½ feet of excess wire back toward the metal tower, and by using the upward position, it furnished a support for the ends of the 11-foot arms. They did not sag, but I felt that they would be subject to more wind vibration if turned down.

I pounded a 3-foot length of 1½-inch pipe into the ground and placed the 8-foot boom with the attached spiders and center T-fixture in the pipe. This gave me a position for attaching the arms and stringing the ¼-inch nylon rope supports. The patio was too short, and the egg crate roof was so low that I could never have gotten the completed beam out. Even in the yard I was short of space, but I managed, even with shrubs and trees.

I drilled a ¼-inch hole in the tops of the vertical arms and threaded ¼-inch nylon rope through. I pulled enough through to reach the ends of the wire, and then tied a knot each side of the vertical arms to keep the rope from slipping. I used a 6-inch length of 7/8-inch PVC pipe with holes drilled in the ends for insulators. I probably did not need the insulators with about 7 feet of nylon rope and a fiberglass support, but habit made me use them. I would probably not use them again, so I suggest you don't bother.

I fastened a Kirk balun to the lower quad spider arm, and it made a fine installation. However, after spending several hours trying to figure out why the swr was about 10:1, I opened up the balun and found that one of the wires, after 20 years of use, had finally broken. I just put it up without a balun. I think a balun might have helped in some ways, but it seems to work well, anyway. I had used a hose clamp to attach the balun to the arm, and it was a neat job. If you use a balun, try this.

I used 31 feet, 4 inches for the director, which is 95%

of the 33-foot length of the driven element. I used a director instead of a reflector because it requires less boom length for the same gain and needed less extra wire pulled back toward the support. There was about 4 feet, 8 inches to pull back on each end.

I checked the swr on the ground, and it was 2½:1 from about 14.200 MHz to 14.350 MHz, except that it dropped to 2:1 in the area of 14.250 MHz. I figured that this would improve when it was up in the air, and it did. At the height of 43 feet, it dropped to 1.5:1 at 14.250 MHz and 2:1 at 14.350 and 14.200 MHz.

I have no rotator yet, so I

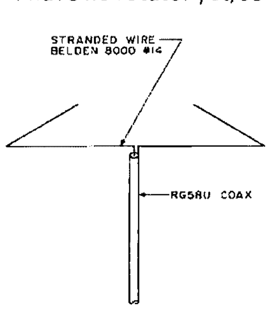

Fig. 2. Schematic of one element.

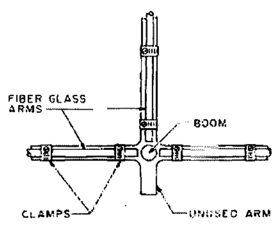

Fig. 3. Closeup of spider.

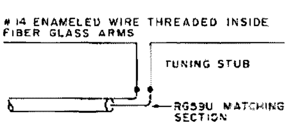

Fig. 4. Schematic of 15 meter driven element.

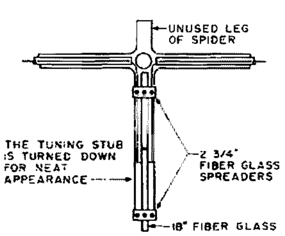

Fig. 5. Closeup of spider.

wanted to face the beam SW. It needed to be attached to a mast to raise it about 5 feet above the 38-foot tower. I had 8 feet of 1½-inch heavy wall aluminum tubing, and I inserted a similar length of 1¼-inch steel tubing inside to make a stiff mast. I drilled a hole and inserted a metal screw to hold the tubing together.

I had planned that we drill the mast for the T-fixture when it was up in the air, but my friend, Bill Burns WA8IEJ, who was going to raise it for me, wanted to drill it on the ground. I think he regretted it when he carried it to the tower. I had told him the beam weight was about 12 pounds, I thought. I had easily carried it on the ground.

While he was carrying it up in one arm and climbing with the other, he stopped to rest a couple of times, and he said it was more like 25 pounds with the attached masting. I recommend that you wait until it is on the tower and drill it before lifting the mast up to the desired height. I let it stick out 5 feet above the tower, which gives me enough inside the tower to attach a rotator.

I later wished I had done one more thing. I should have slipped the wire through a short piece of Teflon™ or nylon tubing as it comes out of the end of the fiberglass arm. This would help prevent the chafing of the wire by the sharp edge of the tubing and might keep the wire from breaking. It probably will last at least a couple of years, though. There is not much pull on the wire, since I did not draw it up very tight, so perhaps it will last longer.

It makes a lot neater arrangement than a 20 meter quad, and up in the air it looks nice.

I used a quarter wavelength of RG-59/U as a matching section from the driven element to the RG-8/U coax lead-in. I guessed that the beam impedance would be about 20 Ohms, and this would raise it to 40 Ohms. This would give an swr of 1.25:1, so the 1.5:1 final measurement was not far off.

When I got a chance to test it, I first called CQ and a California station came back and said that I had a "really strong signal" in his location. Next, I went in a pileup and got a reply, after only two calls, from P29JS in Papua, New Guinea. He said I was 5 x 9. It was a new country for me. The band was going out, so I went to bed.

The next night I tried to talk to a friend, Dale WD8VTD in Jamestown, Ohio, about 19 miles away, but he was off the side of my beam and we were really weak. While I was listening for him, Hans SM6CVX called me and wanted to know my Ohio county. When I told him Fayette, he wanted a QSL card. He gave me 5 x 7 and he was 5 x 8 here. I guess that my front-to-back is probably about 12-15 dB, so it seems I can work Europe off the back OK.

I usually work 40 meters from about 0600 to 0900 GMT, so I don't get on 20 until late. Thus I work mostly Pacific stations.

Last night I called Harry VK3XI and he came back on the first call. He said the band was going out and my beam must be pretty good, as he would not otherwise have been able to work me. He was 5 x 7 here.

I am running just about 800 Watts PEP, so I am very pleased with the results. I think I could have done well with just a 15 meter quad alone and a 1½-inch boom, but I used what I had. My 15 meter quad boom was only 1½ inches x 5 feet long, so I wanted a longer boom. There is no reason why you can't make your own beam from scratch with bamboo or even 1 x 2 wood and a plywood spider. The fact that there is a support for the arms, and the shortened length, bring up many possibilities for a light, cheap beam or even a dipole.

The director is not connected to the boom. The boom is 8 feet long and 2 inches in diameter—a very husky beam.

After seeing my 20 meter compact beam, Kenny Long WB8NGX wanted a 15 meter like it, and I had four arms left, so I decided to build one for him. I used lightweight spiders and a boom from a Kirk 15 meter quad, and of course, I didn't need such a long wire. I only used about 22 feet of wire for a 15 meter beam, so I decided to thread the wire just to the ends of the arms and bend them back an inch, both to hold them taut and to allow for corona prevention. I then had only about 1 foot, 5 inches left in the center.

I pulled this out along another short fiberglass arm, about 18 inches long. See Fig. 5. Then I fastened the wire to the binding posts on a short fiberglass strip. I bolted this to the arm and then added another strip for a spreader. This kept the wire from touching the metal of the spider arm. This was for the driven element.

For the director, I had only about 5 inches left on each side. I used a short piece of PVC tubing bolted to the arm to hold this piece. This wire was not broken, nor was it grounded to the boom. The boom is 6 feet long.

The beam is a very light, neat, and rugged affair. I guessed that it weighed about 7 pounds. I carried it over to Kenny Long's house on the top of a car, not even tied down. We held it down by hand, sticking our arms out the windows. ■

"Weeping Willow" Vertical for 40

—go out on a limb and build one

A vote for the bends.

Art Pightling WA6OYS
240 Louisiana Place
Oxnard CA 93030

There are two things which I look for in a vertical antenna: simplicity (no traps or hats) and availability of parts. A quarter-wave vertical for forty meters fits both of these criteria, but it is often overlooked when antenna construction is contemplated.

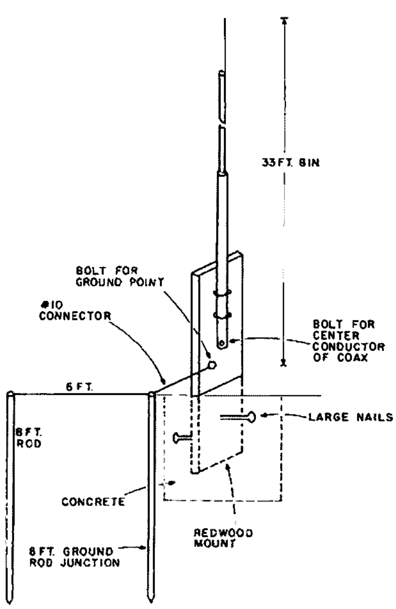

Fig. 1. Forty meter vertical.

There are also two schools of antenna construction: the oak (make it so rigid and strong that it just cannot be destroyed by wind, earthquakes, snow, ice, or whatever) and the willow (able to bend, flex, and take all of the above and spring back). Since the "oak" method never did work for me, this antenna is of the "willow" configuration. It is made of lengths of concentric tubing and ends in a whip.

To determine how much tubing we will need, we have to figure out how long a quarter wave is at forty meters. Using $\lambda/4$(feet)= 246/f (MHz) and then converting the fraction of a foot which remains to inches, we get $\lambda/4 = 33'10''$ for a center frequency of 7.265 MHz. Any center frequency can be chosen by placing that frequency in place of f in the formula.

Construction

Now let's get down to business. The aluminum tubing is available locally in most areas in concentric sizes from 2" to 3/8". I had a 3'×1-1/2"-o.d. piece of tubing on hand, so this was the logical place to start. Now, all we need is 30'10" more. Five 8' sections of tubing were used: 1-1/4", 1", 3/4", 1/2", and 3/8" o.d. After slotting the ends with a hacksaw and clamping the ends with hose clamps, I had 30' of tubing in 6' sections with approximately 2' of each inside the lower tube. An 18" whip was clamped to the top, and the already-on-hand 3'× 1-1/2" tube was attached to

the bottom. Now we have either a very long trout rod or a slightly-oversize quarter-wave antenna for forty meters.

Ground is an important part of a quarter-wave antenna, so ground mounting was chosen. A piece of redwood 3′×4″×1/2″ was found and painted to match my fence. Holes were drilled in appropriate place for U-bolts to hold the vertical to the redwood, and a test fitting showed that the antenna could be securely fastened to the redwood. A couple of large nails were driven into the bottom part of the redwood mount to give the concrete more to grab on to. A 24″-deep hole was dug in an inconspicuous corner of my yard and filled with a 60-pound bag of concrete. The prepared hunk of redwood was then placed in the wet concrete and propped up so that it would be straight when the concrete set. A bolt was put into the bottom of the antenna so that the center conductor of the coax feed could be connected. Another bolt was placed in the redwood mount to serve as a junction point for the ground system. (This bolt must be insulated from the radiating element.)

The Ground System

Some of us have a good ground (swamp or salt marsh) and others don't (rock or sand). My worst-case ground was 120 #18 wire radials, each a little more than a quarter-wave-length long, splayed out sunburst-style around the base of the antenna. The ground system which I wound up with was three radials, six feet long, terminating at 8′ ground rods. These three radials were joined at the antenna base on another 8′ ground rod. I used #10 wire to interconnect the ground rods and the *short* run to the bolt which was previously placed for ground connection on the redwood mount. To be sure, there was a difference in vswr obtainable, but the simpler ground system was satisfactory for my area.

Adjustment

Connect one foot or less of 52-Ohm coax to the antenna, connecting the center conductor to the vertical radiator and the ground braid to the ground connection on the redwood. Connect the vswr meter and the transmitter. Take a reading at the low end of the band, one at the middle, and one at the top. This should be enough to give you an idea of whether to shorten or lengthen the element. If you have built the antenna as described, you will probably have to shorten it a bit. This is best at the top sections. Do your fine tweaking with the whip. You have to take the antenna down each time you want to adjust it, so, by all means, take notes to help you make as few adjustments as possible. When this was done, an swr of 1.2 to 1 was obtained at 7.265 MHz and the swr did not go above 1.6 to 1 in the forty meter band. This was quite acceptable to me. The swr on the top end of fifteen meters was around 2 to 1—not bad for a bonus band.

This antenna has performed well at this QTH and was used when I was net control for the infamous swap net. Using only an FT-101 "barefoot," I was quite well heard in all of southern California, Arizona, and northern California as well. The antenna is also good for DX on forty and fifteen meters because of its low angle of radiation.■

Marine-Band Activity

— a complete guide

Tune in to the world's top traffic.

Between 160 meters and 10 meters, we amateurs generally think in terms of the six HF amateur bands. There are, however, a great many other services operating in those large gaps between our bands. Most hams are aware of some of those other users, such as shortwave broadcasters (Voice of America and Radio Moscow are two examples), if for no other reason than the QRM they cause on the 40 meter phone band at night!

A partial list of the HF band population would include such services as land mobile (U.S. Corps of Engineers, on 5,015 kHz, for example), special industrial, on 4,637.5 kHz (mineral exploration), forestry (in the Pacific Northwest, primarily), and, of course, the military of all nations.

But there is one other major service, one of the oldest, known as the maritime service; that is the subject of this article.

Why is the maritime (or marine) service worth listening to? Because it usually provides the most interesting listening of the communications services (which excludes the broadcast service) and it is the busiest (and therefore easiest to tune in). Also, since it was the first regular user of radio, ship radio has an aura of romance and adventure.

SOS and Mayday — cries for help across the sea — are still heard today, although (thankfully) less frequently than in the past. The famous ship disasters of the last seven decades electrified the public and brought a fleeting fame to the "sparks," as ship operators were known.

Before the SOS was accepted, the most common call for help was CQD, which was made famous in 1909 by Jack Binns, radio officer of the British ship *Republic*. His heroism saved most of the passengers of his doomed ship, which had been rammed by the *S.S. Florida* one day out of New York. Working by candlelight in the January cold, he remained at his key for a continuous 36-hour shift. He delayed his escape from the sinking ship until he knew that help was at hand, risking his life to save the lives of many others.

From the first radio call for help from the British *Goodwin Sands* lightship in March, 1899, through the famous *Titanic* tragedy and the *Morro Castle*, whose smoldering hulk became a tourist attraction when it beached near Asbury Park, New Jersey, boardwalk in the mid 1930s, to the *Andrea Dorea* and the oil tanker sinkings of today's TV news, the tradition of the radio operator's staying at the key until the last possible minute (sometimes losing his life as a result) has remained constant.

I remember following the terrible events of the Texas tower which sank off New Jersey in the early 1960s, from the first Mayday signal to the last announcement that the tower had disappeared with all hands in the horrified sight of the rescue ship. There was a violent gale and there was no way of effecting a rescue. The frequencies used were 2,182 kHz and 500 kHz for phone and CW, both easily heard on an old Navy receiver. That was my introduction to marine radio.

Of course, these tragic

Frequency	Emission		Service
500.0 kHz	A1, A2	(CW)	marine/air
2,182.0	A3, A3A, A3H, A3J	(voice)	marine/air
4,134.3 (ship T) 4,428.7 (ship R)	A3J	(voice)	marine (U.S.C.G.)
6,200.0 (ship T) 6,506.4 (ship R)	A3J	(voice)	marine (U.S.C.G.)
8,241.5 (ship T) 8,765.4 (ship R)	A3J	(voice)	marine (U.S.C.G.)
156.8 MHz	F3	(voice)	VHF marine (ch. 16)
121.5 MHz	A3, A2	(voice/tone)	air/marine*
243.0 MHz	A3, A2	(voice/tone)	air/marine*

*Table 1. Emergency frequencies. *E.P.I.R.B. uses these frequencies — an automatic floating SOS beacon.*

Voice signal	Morse equivalent	Meaning
Mayday	$\overline{\text{SOS}}$ (3 times) (sent as one letter, not S O S)	*Distress*—when there is immediate danger to life or property. Has priority over all other signals. Preceded by "auto-alarm" when time permits.
Pan	$\overline{\text{XXX}}$ (3 times)	*Urgency*—when safety of life or vessel is threatened or if a less immediate danger exists (sickness, out of fuel in open water and no immediate danger, "man overboard," etc.).
Securité	$\overline{\text{TTT}}$ (3 times) (sent 3 letters not as an "O")	*Safety*—when a danger to navigation (hulk in channel, buoy missing, severe weather) exists.
(Voice) Auto-alarm (two alternating audio tones, 1 min. max.)	Auto-alarm (4 sec. on, one sec. off, dashes, one min.)	Sent before Mayday or $\overline{\text{SOS}}$ when time permits, to attract listeners.

Table 2. Priority signals for voice and Morse.

Channel	Frequency*	Channel	Frequency*
4A	4136.3 kHz	22A	22,094.5 kHz
4B	4139.5 kHz	22B	22,098.0 kHz
4C	4434.9 kHz	22C	22,101.5 kHz
6A	6210.4 kHz	22D	22,105.0 kHz

12C	12,428.0 kHz		2,738 kHz
16A	16,565.0 kHz		
16B	16,568.6 kHz		
16C	16,572.0 kHz		

*Table 3. HF ship-ship (plus limited coast) simplex channels. *Carrier frequencies are listed; listen on USB. The above 2-MHz frequencies are not, strictly speaking, in the same category, but are often used for similar purposes.*

events are luckily less common today, due to the availability of search planes and fast boats and the fine job done by the Coast Guard. Yet there are about two or three Mayday calls on 2,182 kHz in a week in the Gulf of Mexico alone. Most are promptly solved by the U.S. Coast Guard or nearby ships with no loss of life.

The bulk of traffic is more mundane by comparison, but still very interesting. Some typical SSB traffic, heard on almost any day, would include oil well drilling operational information, fishing fleet chatter, river tugboats, tankers and freighters talking to their home ports or arranging for supplies at their next port, and international radio telephone (phone patch) conversations. I often receive Germany and English marine operators at my Chicago home. If you wish to copy CW, telegrams, ship supply orders, news, weather, and ship arrival times can be heard if one knows where to listen.

Now that I have (hopefully) aroused your interest and curiosity, you are probably wondering where to listen, so here is a fairly complete guide to the marine bands. The information is as accurate and up to date as possible, being derived from a combination of sources, one of which is the rule book of the International Telecommunications Union — a source of many FCC regulations. To this is added my own experience in working with marine radio as HF-SSB consultant for a large Chicago-based company and as an SWL.

The maritime service is divided into several operational categories, four major frequency bands, and two

City	Primary coast transmit	Primary coast receive	Secondary coast transmit	Secondary coast receive
Boston	2506 kHz	2406 kHz	2450 kHz	2366 kHz

Table 5. Selected high seas marine radiotelephone stations (frequencies are shared).

fundamental station types — fixed (coast) and mobile (ship) stations.

Of primary interest to the amateur or SWL are the frequencies, of course, but a summary of the other information will prove useful, enabling the listener to find the type of station he would like to hear.

The basic operational division is that of radiotelegraph (CW) and radiotelephone (phone) operations. These two divisions are interspersed in alternating subbands throughout the 2-26 MHz portion of the spectrum, plus the VLF bands below 500 kHz (exclusively CW except for some weather broadcasts and foreign broadcasting) and the VHF-FM main band which is exclusively phone. RTTY and special data are used a great deal, but are difficult for most SWLs to decode.

An important fact to keep in mind, with regard to ship and shore stations, is that most of their frequency assignments are duplex (actually half-duplex, or two-frequency simplex, at the ship station), with the two stations transmitting and receiving on different frequencies. This is true of many marine channels, from VLF to VHF. An example, WOO 8-26 (WOO is "Ocean Gate Radio" in New York), is given below under "Reading the Tables." The reason for this duplex operation is that the shore stations usually

Station location	Station callsigns	Typical frequency***
Azores	CUG	6,393.5 kHz
Cuba	CLQ	6,435.0 kHz

Table 7. ITU channels for marine HF use.

have separate receive and transmit sites to reduce interaction between on-the-air transmitters and receivers monitoring other channels, thus providing for a more efficient system. It also helps to compensate for the often inefficient ship, yacht, or boat antenna.

There are also a number of simplex channels, such as 2,182 kHz for calling and Mayday use, and 4,125 kHz for ship-to-ship or limited coast station usage.

These frequencies are spread throughout the range of 2-27 MHz, but the most useful for the average listener are between 4 and 17 MHz, providing high activity both day and night and allowing both sides of the conversation to be heard with one receiver, even far inland. Table 3 lists these simplex channels by number and frequency, while Table 4 lists the most interesting duplex channels by band, station, and frequency.

Morse operation is found on the frequencies listed in Tables 6 and 8.

Although not the main purpose of this article, in the interest of completeness I have included several tables listing all the marine bands from VLF to VHF. One last

Limits (kHz)	Assignable working frequencies for high-traffic ships b)	Limits	Calling frequencies d)	Limits (kHz)
4,172.25	4,172.5 -- 4,177.5 11 frequencies spaced 0.5	4,178	4,178.5--- 4,186.5 17 frequencies spaced 0.5	4,187
6,258.25	6,258.75-- 6,266.25 11 frequencies spaced 0.75	6,267	6,267.75- -6,279.75 17 frequencies spaced 0.75	6,280.5

22,270 --22,320 41 frequencies spaced 2.5	22,322.5 --22,370	22,374

Limit	Calling frequencies	Limit
25,070	25,073.5 --------------- 25,081 6 frequencies spaced 1.5	25,082.5

Limit	Working frequencies	Limit
25,082.5	25,084 ---------------- 25,106.5 16 frequencies spaced 1.5	25,110

(RTTY and data)

Ship stations, wide-band telegraphy, facsimile, transmission systems:

4,142.5 - 4,162.5 kHz
6,216.5 - 6,244.5 kHz
8,288 - 8,328 kHz
12,431.5 - 12,479.5 kHz
16,576 - 16,636.5 kHz
22,112 - 22,160.5 kHz

Ship stations, oceanographic data transmission:

4,162.5 - 4,166 kHz
6,244.5 - 6,248 kHz
8,328 - 8,331.5 kHz
12,479.5 - 12,483 kHz
16,636.5 - 16,640 kHz
22,160.5 - 22,164 kHz

Ship stations, narrow-band direct-printing telegraph data transmission systems:

4,166 - 4,172.25 kHz
6,248 - 6,258.25 kHz
8,331.5 - 8,341.75 kHz
12,483 - 12,503.25 kHz
16,640 - 16,660.5 kHz
22,164 - 22,184.5 kHz

Coast stations, wide-band and manual telegraphy, facsimile, special and data transmission systems and direct-printing telegraph system:

4,231 - 4,361 kHz
6,345.5 - 6,514 kHz
8,459.5 - 8,728.5 kHz*
12,689 - 13,107.5 kHz
16,917.5 - 17,255 kHz
22,374 - 22,624.5 kHz
*plus 8078.1--U.S. Navy, Va.

Table 8. Frequencies assignable to ship radiotelegraph stations using the maritime mobile service bands between 4 and 27.5 MHz.

note on the calls you will hear is that the callsigns follow the same general assignments as amateur calls and a three-letter call is that of a shore station, while a four-letter or letter/number combination is usually that of a ship. Finally, in order to help you read the tables, the following section explains the channel designation numbering system and summarizes what information can be found in the various tables.

Reading The Tables

Many of the frequencies listed have channel designations after the frequency. These refer to the band and number of channels on a particular band. Therefore, a channel labeled "410" tells us that it is a 4-MHz channel, and refers to a particular frequency. Stating the channel as WOM 410, however, tells us that this is a 4-MHz channel of the Fort Lauderdale, Florida, high seas station and is registered as being 4090.9 kHz (ship transmit)/4385.3 kHz (ship receive). These are always half-duplex frequencies.

Weather

Channel	Frequency	Usage
WX1	162.550	NOAA primary weather channel
WX2	162.400	NOAA secondary weather channel
WX3	161.650	Canadian weather channel (ITU channel 21)

Table 9. VHF.

Band (kHz)	Comments
14-160	VLF, Morse, shared with radio navigation and direction finding
255-285	VLF, Morse, shared with radio navigation and direction finding
410 ±5	Reserved for direction finding
415-525	MF-low, Morse—most common ship frequency band in early days—still used for medium range today
500	"SOS" and calling
1605-2850	Morse and voice—primarily old "ship-to-shore" band in "AM" days; mostly being replaced for short range by VHF
3155-3400	Voice, Morse—less common in U.S.
3400-3800	In some parts of world, shared with amateur service
4060-4440	CW, Morse, RTTY—propagation like 75m
6200-6524	Mostly CW with a few ship-to-ship and duplex SSB channels. Propagation like 40m
8194-8815	Voice, CW, many high seas overseas stations at night—propagation like 40m
12330-13200	Voice, CW, many high seas overseas stations during day—propagation like 20m
16460-17360	Voice, CW, many high seas overseas stations during day—propagation like 20m
22000-22720	Voice, CW, RTTY—propagation like 15m
25060-25110	Mostly CW—very long daytime range
156.0-162.6 MHz	VHF-FM, voice, weather. 156.8 MHz for emergency calling—40-mile range

Table 10. Summary of marine bands.

NMO—Honolulu	All use AMVERS
NMC—Pt. Reyes CA	frequencies plus
NMN—Portsmouth VA	following: 4955,
NAM—Portsmouth VA	8150, 8682, 13380,
NGR—Athens, Greece	16445, 12730 for CW
NPN—Guam	
NDT, NPO—Slave stations (for weather)	

Table 11. High seas Navy and Coast Guard stations.

For another example, WOO 811 is one of the 8-MHz channels for New York's (actually located in New Jersey, near Atlantic City) Ocean Gate Radio (8226.0T/8749.9R). Table 4 provides a listing of many of the major world high seas stations and their frequencies. There are two other types of channel numbers: for HF ship-to-ship (a number and letter combination), and for VHF-FM (a simple channel number). These are to be found in Tables 3 and 9, respectively.

In order to find the emergency frequencies quickly, they are listed separately in Table 1, followed by the types of emergency or priority signals heard on them in Table 2.

For those who have transceivers or receivers with spare bands, the various bands, channel breakdown schemes, and voice as well as Morse operation are to be found in the remaining tables.

That's it. Pick out where and what you want to hear, tune it in, and enjoy the excitement and fascination of the marine bands. ■

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 6

the blame, so I can understand the need to try to revise the one lone vote against the project into an even split. It was an ambitious project which might have managed to die on its own accord without the jugular being cut by Tenney . . . but that we'll not know for sure, and so, should amateur radio lose frequencies at WARC this fall, we certainly know where to point the finger. My own evaluation is that the project to interest African countries in the benefits of amateur radio to their people would have worked, just as it did in Jordan, and could have made a decisive difference at Geneva . . . perhaps getting some backing for the US proposal for even more amateur bands.

Future historians interested in getting facts on these ARMA meetings should contact me for copies of the tapes. It's all there for anyone with the constitution to listen through.

FM STARTED IT

The Japanese had no serious foothold in the US with ham gear until the advent of FM and repeaters. I would like to point out that when I started pushing FM in *73 Magazine* back in 1969, I made sure that every US manufacturer of ham equipment knew what I was doing and the impact that I expected it to have. They ignored my predictions, feeling that FM never would be a significant factor in the ham market.

This reminded me of my similar failure to interest the major firms in getting into sideband back in 1955 when I saw that one coming. I talked with Hallicrafters, Hammarlund, National, etc., about it and none of them had any interest at the time. It took Central Electronics to get things moving and the big firms came along when there was no other choice.

By leaving the FM field open to imports, the US industry made it possible for them to set up importing and marketing in this country on a large scale . . . laying the foundation for the 70% penetration we see today. If US manufacturers will be adventurous and try to lead the market instead of follow it, they can sell everything they can make.

CANADIAN HIJINKS

Having received some sanctimonious letters from Canada in response to my criticisms of the ARRL pulling what appears to be a con job on the Canadians, I had someone look into the state of affairs of the supposed incorporation of a Canadian League . . . and nothing could be found filed with the Canadian government. This would lead a naive person like me to suspect that all those promises of untying the apron strings are the usual baloney.

In looking over the list of officers for Canada, I see W2HD listed as their vice president. I dunno why Canadians put so much stock in carpetbaggers and prefer to be run from the US instead of from Canada. Perhaps they are still too weak to stand on their own? Yet, which way is the money flowing? Is it going to Canada or from it . . . and I'm kidding there, because I know as well as you which way the money goes . . . into the bottomless pit down in Connecticut.

MEMBERSHIP DISASTER

The League officials were wearing very worried looks at Dayton. It was difficult to even get them to come forth with a wan smile. It seems that the $18 fee has brought renewals almost to a halt. Now hams are taking a gimlet-eyed look at what they are buying. They see a magazine with few interesting articles . . . they see a lot of back-patting news which is stale before they even get the magazine . . . and ads.

The directors have been trying to get the magazine beefed up, but as the editor complained at Dayton, hardly anyone will write for *QST* anymore. They just don't have the articles—except those from the few staffers who have not yet left the magazine.

SUNSPOT MADNESS

It has not been with a little smugness that we've been watching the sunspot cycle to see how well it would correspond with the model predicted by our resident expert, John Nelson . . . particularly as compared with the predictions for this cycle by the many other experts in the field.

Probably one of the real sleepers in the radio publishing field has been John's book, *The Propagation Wizard's Handbook* ($6.95 from Radio Bookshop, Peterborough NH 03458). John was virtually the only "expert" in the field to have accurately predicted this cycle as it has evolved—and his prediction was way out in left field. He predicted a very low sunspot number for this cycle, with the appearance of a very few large spots instead of the myriad of small spots which have made up the past cycles . . . and he has been absolutely right!

The Nelson book is now being ordered in larger numbers by the scientists at NASA and at Boulder, where the National Bureau of Standards runs a propagation laboratory. Nelson's predictions have been right on the nose, while the government predictions have been noticeably short on accuracy.

There is nothing really new about the Nelson system. He's been using it for about 30 years and has described it in many articles down through the years. When I first ran into his concept of the planets having an influence on sunspots, some 25 years ago, it made a lot of sense to me. I met John when he was giving a talk on his system at a Long Island ham club. I was impressed by his cautious approach and penchant for rigorous attention to details. I noted that only his predictions seemed to stand up, while those of the Bureau of Standards and George Jacobs (VOA) would be frequently in serious error. When John said conditions were going to stink, that was the time to take a vacation. When he said they would be hot, you made sure your antenna was working right.

Oh, what value are these long-range predictions? John wrote an article for *73* quite some time ago telling us what we could expect from the eleven meter CB frequencies during this cycle . . . and his predictions have been most accurate. Since this cycle is unlike any other in history and was predicted by John this way, the effects on both the CB frequencies and the ham bands have been remarkably different from past cycles. Knowing about this ahead of time is valuable in making rules and planning activities. Is it worthwhile to put a lot of development time and money into ten meter repeaters? That depends on propagation.

TURKEY CLUB

One club and one club only refused to cooperate with the ham clubs in the greater St. Louis area on their recent ARCH MARCH hamfest. Their excuse was that as an ARRL club they refused to support any amateur activity where Wayne Green was going to talk.

When I heard about this, I wrote to the club and offered to come to St. Louis a day early and go to a special club meeting where the members could have an opportunity to face me with their beefs and have an opportunity to find out the truth of things they believed on trust from the ARRL. The club flatly refused to face me. Failing in that, I tried to get a meeting with the head of the club and this was agreed upon.

Came the time for the meeting, the only time this chap could make it, at 10:00 pm the night before the hamfest, and the chap didn't show up. I sat and waited for almost an hour, but no message and no club president. I was worn out after a full day of television appearances, meeting the mayor of St. Louis, and other meetings. When the chap didn't show, I went to bed to get rested up for the busy hamfest on the day to come. I had to be up very early to set up our booth, get set for my two major talks that day, etc.

Suddenly, the phone rang . . . our friend had finally gotten to the hotel. He got angry when I said I wouldn't get dressed again and come down to argue with him for an hour or so. I had gone to a lot of trouble to make the time available for him—which was wasted—and I was not about to stay up a good part of the night and thus make my talks the next day less entertaining just because he was unable to keep an appointment.

Phooey.

MARCH WINNER

"The NCX-Match" was a close winner over K6IQL's "The 10-GHz Cookbook" in our March Reader Service card balloting, so Rick Ferranti WA6NCX/1 (Newton Centre MA) will be receiving our $100 bonus check for being the author of that issue's most popular article.

Ham Help

I would appreciate it if anyone could help me connect a Heathkit HG-10B vfo to my Swan 500CX to be used as an outboard vfo.

RTTY Loop

from page 14

Certain characters, not represented in Baudot, have an $FF stored at their location. This directs the program to use the special table (SPLTBL), located from $80 to $A6. The table is organized as a three-byte, fixed-format table. The first byte is the ASCII character, and the next two are the Baudot codes for the two-letter symbol for each ASCII code.

The main program starts at $0100 by setting up the stack and initializing the PIA, addressed to port 7, as an output. A character is input through the monitor's input routine and used as the index for the table. If the retrieved character is $FF, the ASCII code needs a special character representation, and a branch to SPLCHR is executed. A retrieved null, $00, initiates a branch back to input, with no output produced. One more test and we're ready to fly. If the retrieved character is a space ($90 in Baudot), a check is made on the running total characters in the line. If it is greater than sixty, forget the space and send a carriage-return, line-feed sequence. If it is not a space, hooray—we put it out.

First things first, the MSB is shifted into the carry bit, where it can be used to set or reset the software flip-flop used to monitor case. This was well diagrammed last month and will not be detailed here. Each of the five data bits is then shifted out and sent sequentially, after a character START bit is sent, and a STOP bit, 33 milliseconds of pure MARK, is plastered on at the end.

Now things are going to get a bit tacky. Each data bit must be sent for exactly 22 ms. The timing is set in a software delay loop, called MSEC10, set for approximately an eleven ms delay.

Program 1 (continued).

Since this delay is produced by loading a number Into the index register and decrementing it, the speed of the computer's clock can make a significant difference in the delay.

For the "original" SWTPC 6800, with the MP-A CPU board, the clock speed is roughly 902.255 kHz, and a delay constant of $0480 is used. If you have the MP-A2 CPU board, your clock speed may be anything from about 900 kHz to 1.5 MHz. To find the constant that is right for your system, enter Program 2 into your computer and type "G". Time, exactly, the interval, in seconds, between the "B" and "E". Use the formula shown in Fig. 1 to calculate your delay constant. Remember, this is hexadecimal arithmetic. Work through the example to be sure you've got it right.

One more thing to do before we can use the program on the

Program 2.

```
                      NAM    CLKSPEED

air: Interface it. The data is coming out of bit 0 (the LSB) of the A side of a PIA interface on port 7. This TTL level signal represents MARK with a high and SPACE with a low. If you have an ST-6 or equivalent, interfacing may be accomplished easily, adding only one diode, as described several months ago for the test generator. Other interfacing schemes could include an opto-isolator or reed relay. Remember, though, *don't* allow the loop voltages access to the computer or you will have a smoking pile of expensive "junque."

If all goes well, when you load the program, adjust the delay constant, and accomplish interfacing, any character struck on the keyboard should come out in Baudot on the other end.

General Formula:
"Constant Delay" × "Constant Time" = "New Delay" × "New Time"

Constants for MP-A System:
Constant Delay = $480 (1152 Decimal)
Constant Time = 332 Seconds

Practical Formula:
$\frac{1152 \times 332}{\text{New Time}}$ = New Delay

An Example:
MP-A2 System Time = 234 Seconds
$\frac{1152 \times 332}{234}$ = 1634 = $666 New Delay

Fig. 1.

Now, one last hooker: If you are using an MP-C "control interface" (the one that was supplied with the computer if it had an MP-A CPU board) and you type in a character while one is sending, you will get garbage. This is an unfortunate result of the software UART written into the MIKBUG™ or SWTBUG™ monitor to handle serial data through a PIA interface on port 1. Yes, I know we are doing essentially the same thing on port 7, but that is the problem. While the system will support one delay loop, it will not support two running at the same time. The solution is to take one of the I/O structures out of a *software* UART and into a *hardware* UART, or ACIA. The easiest way to do that is to use a serial MP-S interface for control on port 1. Now, characters input during an output are simply ignored. Not an ideal solution, but adequate for this simple program.

Next month, we'll . . . no, I'm not going to tell you! There are few surprises in life; let one of them be next month's RTTY Loop.

Contests

from page 19

Phone—3920, 7260, 14300, 21360, 28600, 50.3, 145.1.

Use of FM simplex is encouraged but no repeater contacts are allowed.

AWARDS:

A plaque to the top RI and non-RI scorer, plus certificates will be awarded to the top scoring station in each RI county, state, province, DX country, the top scoring Novice and Technician station in each RI county and state, and the ARC in each state, province, and DX country that submits the highest aggregate score with a minimum of 3 logs per club.

ENTRIES:

Logs must show date/time in GMT, call, exchange, band, and mode. On a separate sheet show name, call, mailing address, club affiliation if any, total QSO points, multiplier claimed, and final score. Entries must be postmarked no later than August 31. Send logs and summary to: East Bay Amateur Wireless Association, PO Box 392, Warren RI 02885. Include an SASE for results.

NEW JERSEY QSO PARTY
Contest Periods:
2000 GMT Saturday, July 28 to 0700 GMT Sunday, July 29
1300 GMT Sunday, July 29 to 0200 GMT Monday, July 30

Sponsored by the Englewood Amateur Radio Association, the contest is open to all amateurs worldwide for the 20th year. Phone and CW are considered the same contest. A station may be contacted once on each band. Phone and CW are considered separate bands, but CW contacts may not be made in the phone segments. NJ stations may work other NJ stations. General call is "CQ NJ." NJ stations are requested to identify themselves by signing "DE NJ."

EXCHANGE:

QSO number, RS(T), and QTH (ARRL section or country/NJ county).

FREQUENCIES:

1810, 3535, 3900, 7035, 7135, 7235, 14035, 14280, 21100, 21355, 28100, 28600, 50-50.5, and 144-146.

Suggest phone activity on the even hours, 15 meters on the odd hours 1500 to 2100 GMT, 160 meters at 0500 GMT.

SCORING:

Out-of-state stations multiply number of complete contacts with NJ stations times the number of NJ counties worked (21 maximum). NJ stations score 1 point per W-K-VE-VO QSOs, 3 points per DX QSO. Multiply total number of points times the number of ARRL sections (including NNJ and SNJ—75 max.). KP4, KH6, KL7, KZ5, etc., count as 3-point DX contacts and as section multipliers.

AWARDS:

Certificates will be awarded to the first-place station in each NJ county, ARRL section, and country. In addition, a second-place certificate will be awarded when four or more logs are received. Novice and Technician certificates will also be awarded.

ENTRIES:

Logs must show GMT date/time, band, and emission, and be received not later than August 25. The contact for each claimed multiplier must be indicated and numbered and a checklist of contacts and multipliers should be included. Multi-operator stations should be noted and calls of participating operators listed. Logs and comments should be sent to: Englewood Amateur Radio Assoc., PO Box 528, Englewood NJ 07631.

A size #10 SASE should be included for results. Stations planning active participation in NJ are requested to advise the EARA by July 7 of your intentions so that they can plan for full coverage from all counties. Portable and mobile operation is encouraged.

ENDEAVOUR AWARD

The Royal Naval Amateur Radio Society already sponsors two awards, the Mercury Award for contacting members of the Society, and the Hampshire County Award for contacting amateurs in the English county of Hampshire. The Society now has great pleasure in announcing a third award, called the Endeavour Award, for contacting Society members residing in Australia. The title of the award links the Royal Navy with Australia and the award is open to all radio amateurs.

Applicants must establish two-way amateur communications with RNARS members residing in Australia. Points will be awarded on the basis of one point per VK RNARS member worked per band, after the commencement date of January 1, 1979. To qualify, the following is required: for amateurs residing inside Australia—15 points; for amateurs residing inside Oceania—10 points; for amateurs residing outside Oceania—5 points.

In addition, for amateurs residing outside Oceania, contacts with VK RNARS members on the 3.5 MHz band will count double points. For the purposes of this award, any RNARS maritime-mobile member when located inside Australian waters may be counted as a VK member.

The award will be endorsed only on the request of the applicant and the following endorsements are available: all CW, all SSB, all 3.5 MHz, all 28 MHz, all Novice, and five-by-five, the last endorsement being for gaining at least five points on each of the five high frequency bands.

To claim the award, no QSLs are required. However, full log details showing the VK member (or /MM + QTH) worked, their RNARS number, date, time, frequency, mode, plus an application fee of $1.50 Aust or 7 IRCs are to be sent to the Endeavour Award Custodian: R. Baty VK5MD, 43, HMAS Australia Road, Henley Beach South, SA 5022 Australia. Please ensure all checks are in Australian currency and made payable to "R. Baty." Clearly state what endorsements are claimed. Certificates to successful applicants will be forwarded by airmail as soon as possible after the claim has been checked.

TESLA COMMEMORATIVE AWARD

A very attractive award is being offered by YU2EAB, the Gospic Amateur Radio Club, to commemorate the birth of Nikola Tesla. To obtain this award you must work the special station YU0NT for 5 points plus any other Gospic station for one point. Six points are needed for the award. No band or mode restrictions exist. YU0NT will operate from July 7 through July 17 from the house where Nikola Tesla was born. Some of the other stations to look for in Gospic include YU2CET, YU2CGE, YU2CGG, YU2CPJ, YU2CTK, YU2CUD, YU2EAB, YU2RWI, YU2RWY, and YU2VE.

No QSLs are necessary to obtain the award; send only the usual log data along with 5 IRCs or $2.00 to: YU2EAB, Box 55, 48000 Gospic, Yugoslavia.

Looking West

from page 12

more fitting than this contact. Fate had been very kind indeed.

The station operates under the callsign W6RO—W6 "Rolling Ocean"—as a tribute to one of the founding members of the club sponsoring the overall *Queen Mary* wireless operation. Amateurs wishing to operate from the *Queen Mary* can do so in one of two ways. Those living in the area and wishing to serve as scheduled volunteer operators can contact the Associated Radio Amateurs of Long Beach and make their intentions and availability known. However, if you are planning a trip to Los Angeles and would like to operate the station, you can take the *Queen Mary* tour and, when it gets to the wireless room, locate the operator in charge and explain your desires. You will have to present your original amateur license and some additional identification before you will be permitted to operate. Guest operating periods will be approximately 15 minutes in duration.

Currently, two motion pictures are in production which in part are being done aboard the *Queen*. One is the epic film "Titanic," scheduled for release late next year. The other hits much closer to home. In early September or thereabouts, the ARRL will be releasing its new film, "The World of Amateur Radio," produced by Emmy-award-winning filmmaker Dave Bell W6AQ. Thanks to Nate and his organization, Dave was able to film the narration sequences (which feature NBC News correspondent Roy Neal W6DUE) aboard the *Queen Mary*.

Dave has made one request of the amateur community now that the news of the new film has been made public. It will be several months before the film is ready for distribution. Please do not call either Dave or the ARRL requesting the film until its availability has been announced. The initial prints are destined for showing at the World Administrative Radio Conference in Geneva in order to underline the attributes of the worldwide amateur service. Eventually, there will be enough prints for all of us to see, so it is suggested that you monitor *QST, HR Report,* The Westlink Amateur Radio News, and this column to find out the availability date. Your cooperation in this regard is deeply appreciated.

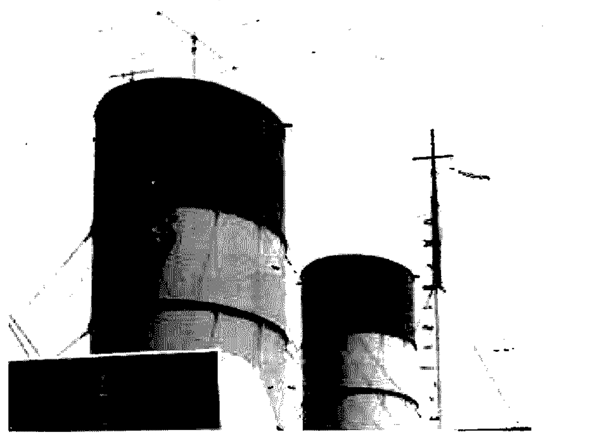
THE "THEY-WON'T-LET-220-DIE" DEPARTMENT

The 220-SMA of southern California has gone on record as being willing to take any action necessary to ensure that the 220-to-225-MHz amateur band never falls into the hands of maritime interests. To show that they really mean business, what is called a "WARC Action Committee" was formed at their April 22 meeting, with Ray Von Neumann K6PUW as its chairman.

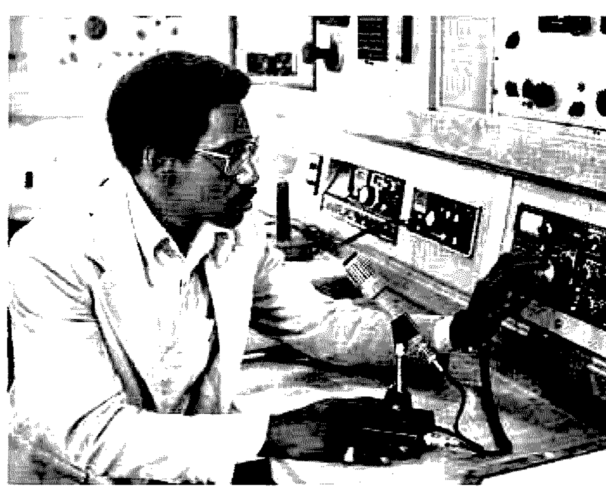
At present, a number of directions are being considered, although two tend to offer the most promise of at least marginal success. The 220-SMA may well have hired a Washington-based attorney by the time this reaches print. His job will be to go into federal court and either file a direct appeal on the matter or request an injunction barring the use by our WARC delegation of the portion of the US WARC proposal dealing with the 216-to-225-MHz spectrum. It is the 220-SMA's contention that both the FCC and the maritime services may have violated the Federal Administrative Procedures Act in regard to the preparation of that portion of the document. One lawyer explained to me that if the 220-SMA were successful In obtaining such an order, then our delegation would be barred from discussing or voting on issues brought before WARC dealing with that spectrum. This could place the US in a rather awkward position at the conference later this year, but the same legal expert did say that he did not feel the 220-SMA could obtain such an order. I thus suspect that any legal action will come in the form of an appeal. Only time will tell where the 220-SMA will go if they choose this route at all.

Another direct offensive action they are considering—one I expect to see initiated quickly—is filing a formal Petition for Rulemaking with the FCC requesting the immediate transfer of currently unused maritime VHF spectrum to the amateur service. The feeling is that the

Joe Rudi WA6PVA, baseball player with the California Angels, makes the first official QSO from W6RO. Looking on is Nate Brightman K6OSC, of the Associated Radio Amateurs of Long Beach, the club which installed the gear. (Photo by W6VGQ)



A new triband addition to the Queen Mary. *(Photo by KH6IAF)*



TV actor/comedian Stu Gilliam WD6FBU operates W6RO, the new amateur station aboard the Queen Mary. *(Photo by W6VGQ)*

need for this can be easily documented by showing the overall inactivity in current VHF maritime operations and the current growth patterns in VHF amateur activity. Basically, the 220-SMA feels that it is time to stop being on the defensive and become outward and aggressive in fighting to save our spectrum. They hope to rally support not only from 220-MHz spectrum users, but also from the overall amateur community.

Already, some words of support have been voiced, such as the following statement issued by the Jet Propulsion Laboratory's Amateur Radio Club: "The Jet Propulsion Laboratory's Amateur Radio Club supports the 220-SMA of southern California in its efforts to keep the 220-to-225-MHz band an amateur one. To this end we have pledged our support." The JPL ARC did more than just add a bit of encouragement. They also provided the facilities and hosted the meeting.

THE "NAVY-TO-THE-RESCUE—MAYBE" DEPARTMENT

The 220-SMA sent copies of its since-denied Petition for Reconsideration to several government agencies in addition to the FCC. Among those who received copies were the nation's military branches. Just prior to the April 22 meeting at JPL, the 220-SMA dropped what might best be described as a bombshell. It had been contacted by the Chief of Naval Operations and had been told that neither the Chief's office nor the Naval Telecommunications Frequency Management Group had ever been informed of any proposed reallocation of the 216-to-225-MHz spectrum. As it turns out, the Navy has a rather vested interest in this spectrum. It operates what is known as the Space Surveillance Systems Group, a nationwide communications network that keeps track of all space debris resulting from US space operations. In fact, the Space Surveillance Systems Group utilizes frequencies from 216 through 233 MHz, according to an SMA-220 spokesman, and is what is termed a "long-term, high-monetary-investment naval operation."

Needless to say, the Navy is more than just a bit upset over finding out that it may be evicted along with the amateur service from spectrum in which it has a definite interest. Apparently, it is upset enough to have ordered the Telecommunications Frequency Management Group to start a detailed investigation of the matter and report their findings back to the Chief's office. What seems to have irritated them the most were the official statements contained in the WARC position paper itself, rhetoric that said this proposed transition had been cleared with the military prior to its inclusion. If this is true, then I wonder whose military the FCC and maritime services cleared it with. According to the Navy, it wasn't ours.

THE "I-NEED-A-FOREIGN-CORRESPONDENT" DEPARTMENT

Is there an amateur in Geneva, Switzerland, who happens to read Looking West? If so, I need your help. I need a volunteer to act as a Looking West correspondent during the World Administrative Radio Conference later this year. His or her job would be to sniff out any news of what's happening at the conference in relation to VHF/UHF spectrum matters, write same into a monthly synopsis, and forward it to me for inclusion in this column. If you have both the time and interest, drop me a line at the address given at the column's top and we can go from there.

THE "BIG-CHANGE-AT-WESTLINK" DEPARTMENT

Actually, there has been more than one change, but the one that affects most Westlink service users is the discontinuance of their "Cassette Exchange Program." Effective immediately, the cassette program has been replaced by an automated telephone system that permits those wishing to obtain the weekly newscasts to simply dial a telephone number in order to obtain the information.

There were two reasons for Network Director Jim Hendershot to make this decision. First, the Westlink News Service has grown far larger than he ever expected. This is a free, nonprofit service, but he found himself spending virtually every free moment duplicating tapes. He could have gone to a high-speed duplication house to have this work done, but it would have meant going away from the free aspect of the operation and possibly charging upwards of $100 or more annually for the service. This he did not want to do.

Second, there have been ongoing postal problems. Not a week had gone by when a subscriber didn't call to complain that his tape had not arrived or that it had arrived too late to air that week. Consequently, Jim has dropped the cassette exchange system.

There has been a second big change at Westlink. Alan Kaul W6RCL, Bill Orenstein KH6IAF/6, and I recently produced a 20-minute documentary entitled "The Peril to 220" which covered the many aspects of the current situation in that spectrum. The response to that special was so positive that Jim asked us to continue producing such programs on a monthly basis. We have accepted the assignment. In fact, currently in production are programs dealing with the OSCAR satellites, DXing from DX lists, and handling malicious interference.

To accomplish this, a second Westlink studio is being assembled at Bill's office in Hollywood; by midsummer, we should be in full production. Distribution will also be via a dial-in telephone number. We will also be setting up another telephone number so that amateurs can leave input for either the weekly newscast or the monthly "magazine of the air." Those interested in obtaining either or both of these services should contact Jim at the Westlink Radio Network, 8331 Joan Lane, Canoga Park CA 91402. Jim no longer must limit the service to repeaters and bulletin stations, so the service is available to just about anyone.

DX

from page 27

The following information has been provided by OK3BG on OK3TAB/D2A. OK3TAB is Laci Toth who arrived in Angola in March. He went to Luanda on a long business trip and was able to get on the air almost immediately. Laci is using a home-brew transceiver running 200 Watts to a triband quad. Look for him after 1700Z around 21360 kHz or 14250 kHz. He seldom strays far from these frequencies. QSLs have already been printed and you can QSL via OK3ALE or through the OK bureau.

Alex Kasevich W1CDC passes along the word that he is planning an extended stay on Montserrat beginning in August when he will be signing VP2MM. Look for him on CW only in the lower 25 kHz listening up 5. QSL to his home call with an SASE, of course.

The 1978 annual report of the Hong Kong Amateur Radio Transmitting Society lists 56 full members, 31 associate members, and six overseas members. With VS6FE as president, the group has an active 2-meter repeater and conducts the nightly Cantonese Net on 14130 kHz. VS6GW runs the QSL bureau at Box 541, Hong Kong.

The Gilbert Islands become independent on July 10 with the present KH1/VR1 prefixes being replaced by one new prefix. Prefix hunters must be going crazy these days trying to keep up.

14240 kHz and 14275/280 kHz are good areas to monitor for various list-type operations, generally after 2300Z.

Joe Ely 7P8BI reports that anyone needing a card for his 3D6BL operation from September, 1977, to August, 1978, or his present stint in Lesotho can QSL to his new manager, Gary Yarus WB0MSZ, 921 N. Clay Avenue, St. Louis MO 63122.

The Mad River Radio Club managed over 4,000 contacts during the ARRL CW DX Contest from FG7AR/FS7 for a score of some 3.4 million points. All contacts from March 14 to March 20 should be QSLed to K8OCR. Neither FG7AR nor his managers have records for contacts during this period.

The Sorel-Tracy Amateur Radio Club, VE2CBS—Province of Quebec, will sponsor a DXpedition to Zone 2 this month to aid those needing this rare zone to fill out their WAZ Award.

The operation will take place the week of July 21—July 28. They plan to operate all amateur frequencies using both CW and SSB.

As club Public Relations Director Marcel Lapolice VE2EML, would say, "Au plaisir de vous recontrer sur les ondes durant cette semaine de DXpedition dans le nord de la province de Quebec." Right on, Marcel.

That station on during the WPX contest signing HD1A was a multi-multi operation by K7CA, WA4UAZ, K4ERO, and KA6CNS. HD1 is a special Ecuador prefix and you can obtain a QSL by dropping an SASE to WA4QMQ.

That about covers it for this month. We hope some of the preceding information will help you pick up a few new ones. In the meantime, we are always looking for DX information and photos. Photos can be either black and white or color. We in particular need information pertaining to CW, SSTV, OSCAR, VHF/UHF, and 160 meters. Thanks as usual to the *West Coast DX Bulletin*, LIDXA *DX Bulletin*, and *Worldradio News* for much of the preceding information.

LPK logic probe from CSC.

CSC LOGIC PROBE KIT OFFERS KIT-BUILDERS MULTIPLE BENEFITS

For Continental Specialties Corporation, already well known as a manufacturer of professional digital trouble-shooting instruments, their first kit-style test instrument logically emulates their line of logic probes. Both as a kit and as a probe, the CSC Model LPK Logic Probe Kit represents an excellent value.

The kit instructions are exceptionally well-written, offering step-by-step assembly procedures. Solder, wire, and all miscellaneous hardware are included in the kit—along with the printed circuit board, case, and all components, of course—leaving no extras to buy. Even beginning-level kit-builders can assemble the LPK quickly.

Once assembled, the LPK offers respectable performance as a logic probe. It is circuit powered through attached clip leads. HI, PULSE, and LO LEDs display logic states and transitions. The high logic state is defined as 70% or more of the supply voltage, the low state as 30% or less, making the probe compatible with most digital logic technologies or families. With its high (300,000-Ohm) input impedance, circuit loading is minimized.

With the LPK, even very narrow pulses can be detected. Internal circuitry stretches pulses as short as 300 nanoseconds into 1/10 second flashes of the PULSE LED; pulse trains at repetition rates up to 1.5 MHz keep the PULSE LED flashing.

The LPK includes self-protecting circuitry which permits the power leads to be connected in reverse or to as much as 25 V dc without permanent damage; the probe tip, similarly, can contact ±50 V continuously or 110 V ac for up to 15 seconds without permanent damage to the probe.

As a troubleshooting tool, the LPK holds its own against any logic probe in all but very high speed applications. As an educational venture for the kit-builder, it should be noted that the LPK, while a digital tool, is based on analog circuitry, offering a unique opportunity to see how the two disciplines merge.

The LPK Logic Probe Kit is available through selected local distributors both in the US and around the world.

For more information, or for the name of your nearest CSC stocking distributor, call *Continental Specialties Corporation, 70 Fulton Terrace, New Haven CT 06509; phone (203)-624-3103, TWX (710)-465-1227.* Reader Service number C9.

IC INSERTION TOOL

The new Model MOS-2428 DIP Inserter handles all MOS, CMOS, and regular 24- and 28-pin ICs. This unique new insertion tool also aligns bent-out pins. Simply rock the IC on the straightening saddle to align the pins. Press the tool over the IC to pick it up, then simply place the tool onto the socket and depress the plunger for instant and accurate insertion. The tool features heavy chrome plating throughout for reliable static dissipation. It includes a terminal lug for attachment of a ground strap. The MOS-2428 IC Insertion Tool is available from your local electronics distributor or directly from *OK Machine and Tool Corporation, 3455 Conner Street, Bronx NY 10475.* Reader Service number O5.

FREQUENCY COUNTER PREAMP

This general-purpose counter preamp has up to 25 dB gain from 10 MHz to 1 GHz. Designed to front-end a frequency counter's 50-Ohm VHF/UHF input, the AP-8015 preamplifier can be used with an antenna or pickup loop as well as be direct-coupled to allow low-level signal sources to be counted. The AP-8015 includes a 115 V wall plug transformer for ac operation as well as a dual 9-volt battery harness for portable operation. The preamp is enclosed in a heavy-duty anodized aluminum case. Size: 4-1/8" L x 2-1/4" W x 1-1/4" D. Weight: 6 ounces. For orders or Information, contact *Optoelectronics, Inc., 5821 N.E. 14th Avenue, Ft. Lauderdale FL 33334; phone (305)-771-2050/1.* Reader Service number O3.

FSK-1000 DEMODULATOR FROM IRL

"This is not a sedan or a truck. This is a sports car."

That's how the engineers at iRL describe their new FSK-1000 demodulator.

The FSK-1000 is a new, sophisticated, two-tone limiterless demodulator which offers selectivity as narrow as 55 Hz in each of its matched, selectable-bandwidth, active-filter tone channels. Although it includes such "extras" as continuously adjustable shift, dual-mode autostart, and a keyboard-activated switch, the designers insist, "We don't want a family sedan dressed up with mud flaps and raccoon tails. We want to give the serious HF or VHF operator a TU with the best raw performance available anywhere."

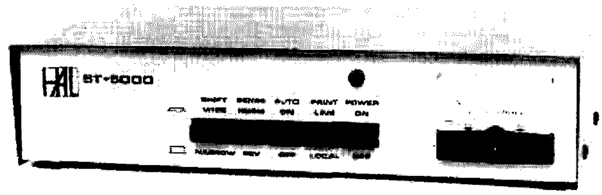
The FSK-1000 has both high-voltage current loop and low-voltage (RS-232 compatible) outputs to interface readily with mechanical teleprinters, computers, or both.

Receiver tuning requires a careful touch with the narrow filters switched in, but this gives the serious operator the selectivity he needs when the QRM gets really bad.

The FSK-1000 circuitry utilizes 48 operational amplifiers (twenty FET types) and a host of other devices. Complete details are available from iRL dealers or by writing *iRL, 700 Taylor Road, Columbus OH 43230*. Reader Service number 127.

NEW RTTY TERMINAL FROM HAL

HAL Communications Is proud to announce a new compact and low-cost RTTY terminal—the DS2000 KSR. The new terminal features operation with Baudot, ASCII, and Morse codes (Morse receive optional) and incorporates many of the features of more expensive terminals. A new 72-character line by 24-line display format, two 32-character programmable "Here Is" messages, and CW identification at the touch of a key simplify operation. A terminal-status line keeps the operator aware of data rate, data code, and other terminal conditions. Text is transmitted one word at a time and editing is possible anywhere In the line being composed. All terminal functions are controlled by a combination of a control key and a key from the top row of the keyboard. Other deluxe features such as unshift-on-space, synchronous idle, keyboard-operated switch, and both QBF and RY test messages are available at the stroke of a key. Connect the DS2000 KSR to a standard 18-120 mA, 200 V dc (maximum) current loop for Baudot and ASCII operation. Morse output is accomplished via a transistor switch to ground for keying either "grid-block" or "cathode" circuits. An optional Morse receive board (MR2000) is available for reception of Morse code at rates from 1-175 wpm and is customer installable allowing purchase at any time. An optional 9-inch diagonal measure video monitor is also available. The terminal weighs 6 lbs. (2.75 kg) net (10 lbs/4.55 kg shipping) and comes in an attractive blue and beige cabinet. Contact *HAL Communications Corp., PO Box 365, Urbana IL 61801*, for further information.



DS2000 RTTY terminal from HAL.

ROHN NO. 25 FOLD-OVER TOWER

When an amateur thinks of towers, chances are that he thinks of Rohn. And for good reason. Rohn has been building towers for a long time, providing amateurs with a variety of top-quality models at a reasonable price.

Recently, when I needed a new tower, my thoughts turned naturally enough to Rohn. Getting out their catalog, I thumbed through it to see just what they had to meet my particular requirements. After a few minutes of browsing, I decided that the 48-foot No. 25 Fold-Over was just what I was looking for.

Among the considerations I had in mind while choosing a new tower was that it get my beams clear of adjacent buildings and trees but not be so tall as to stand out prominently from its surroundings. As a result, I concluded that it should be approximately 50 feet high. And, since I prefer to keep my feet firmly on the ground, it should fold over so that work on the beams and rotor could be done from the ground or, at most, while standing on a short stepladder.

I also felt it highly desirable that the tower be easily assembled and disassembled by two people. And the likelihood that I would want to relocate it within the foreseeable future meant that it should be readily transportable, preferably in a small pickup or van. In addition, it should be rugged, durable, and easy and inexpensive to maintain. And, of course, it should be affordable.

The more I studied the Rohn catalog, the more I became convinced that the No. 25 Fold-Over was the answer. While I had never owned a Rohn tower, I was quite familiar with those used by friends and had been very favorably impressed by what I had seen. I liked the way they stood up to everything from hurricane winds in my native Florida to severe New England ice storms.

No. 25 towers utilize heavy-duty 1¼-inch-diameter #16-gauge steel tubing for side rails in a 12½-inch equilateral triangular design with solid-steel zig-zag cross pieces, entirely electrically-welded and fabricated by precision machines. There are 8 zig-zag steps per 10-foot tower section. Design and construction enables No. 25 towers to be installed at guyed heights up to 200 feet.

The tower's hot-dipped zinc galvanizing provides protection from rust and corrosion. A minimum molten zinc coating of 2 ounces for every square foot of surface fuses permanently to the metal, becoming an actual part of the steel so that it cannot be separated. Also, the tubular steel used in the towers is coated both inside and out to provide protection against deterioration from condensation and moisture. If a galvanized surface becomes scratched or chipped, the surrounding zinc actually "heals the wound" and continues to seal out corrosive elements.

Double-bolted joints are used to join tower sections for sturdiness and dependability. The No. 25's strength allows it to be self-supporting, provided a house bracket is used; it can go 35 feet above the bracket under normal conditions. A 200-foot No. 25 tower will withstand a 30-lb.-per-square-foot wind load—equivalent to 86.6 mph true wind velocity—when guyed and installed according to the manufacturer's specifications. This includes an antenna with an area of 6 square feet as well as 2 transmission lines. Those figures made me confident that a 48-footer with the sort of antennas I planned to use should be almost indestructible under typical New England weather conditions.

One of the things I like best about the No. 25 Fold-Over is the variety of mounting options that are available, covering virtually any situation you're ever likely to face. In addition to the more or less standard short base section for concrete, there is a hinged version for mounting in concrete, hinged and non-hinged base plates for use with concrete, plus mounts for flat and peaked roofs. And, also available and especially handy for Field Day, are a single drive-in base and a base plate for use with drive rods. If you can't guy, or you simply prefer not to, there are several sizes and types of house- and eave-brackets available. In my own case, I decided to install the tower at the rear of the barn using a house bracket for support.

In choosing a location for the tower, care should be taken to ensure that it will be well clear of trees, wires, buildings, and other objects, to permit a free swing of the hinged portion of the tower and antenna. If guys are to be used, the location should be suitable for placing four guy anchors at the appropriate distances.

The work begins with the digging of a hole 30 inches square by approximately 36 inches deep. After spreading a couple of inches of gravel in the bottom of the hole, attach the base section to the first 10-foot section and set the assembly on the gravel. Then spread another 3 inches of gravel around the legs of the base. This allows the tower base legs to extend the required amount below the base of the concrete, thus allowing for drainage of moisture into the gravel.

Before pouring the concrete, coat the base section over an area about 3 inches above and 3 inches below the space where the top of the concrete base will be, using a water-proof asphalt-type material. If the tower is situated near a building, be sure that the base is set so that two of the tower legs lie in a plane perpendicular to the wall of the building. This will cause the hinge axis to also be at right angles to the wall, and the tower will fold clear of the building. With the base set, pour the concrete around it and check its plumb with a carpenter's level on one or more of the legs of the tower. The top of the concrete should be slightly crowned to

prevent water accumulation.

It's a good idea to allow at least three days for the concrete to harden before continuing to erect the tower. An erection fixture or gin pole will make the process easier and faster, especially if you decide to add one or two additional 10-foot sections, bringing the total height to 58 or 68 feet.

If you're doing a 48-footer like mine, you place the hinged section atop the second 10-foot section, making sure the shipping-tab bolt is closed and that the hinge is positioned on the correct side of the tower. Guy wires (if used) are then installed on the guying tabs near the hinge point. The next step is to align and bolt together the two pieces of the boom (lever) section. The boom is then attached to the hinged section. Be sure the hinge bolts are loosened before you attempt to fold the tower over. If practical, a house- or eave-bracket may be used at the hinge point in place of guy wires. The bracket must be placed within 2 feet of the hinge point.

The remaining sections are lifted into place and installed in the usual manner. Next, the winch and cable mechanism is bolted to the leg of the lower tower section, just below the clevis on the boom. If an additional 10-foot tower section has been placed below the hinge section, an extra pulley must be installed just below the clevis on the boom. Finally, the cable must be secured with clamps and a wire rope thimble to the boom clevis and to the winch.

That's all there is to putting up a Rohn No. 25 Fold-Over tower. The installation instructions are quite simple and straightforward. Follow them and you'll get your tower up quickly, easily, and, most important of all, safely!

Once the hole is dug and the base assembly is installed, two people can complete the job in a morning or afternoon, including mounting a rotor and beam. Then you can sit back and enjoy operating, secure in the knowledge that if you pull routine preventative maintenance a couple of times a year and take prompt care of anything that crops up between times, you'll have a setup that should provide many years of reliable service.

While the 48-foot No. 25 Fold-Over tower proved just right for me, it may not be what you need. In that case, you should check out the other versions of the No. 25, as well as the many other models available from Rohn. For more information, write *Unarco-Rohn, a Division of Unarco Industries, Inc., 6718 West Plank Road, PO Box 2000, Peoria IL 61656.* Reader Service number U2.

LETTERS

from page 10

windows at the higher elevations to Midland, El Paso, and Carlsbad. For the NBVM QSOs, we are carrying a GE Microcassette recorder.

All radio systems will be powered directly, without the use of a battery, from a 72-cell solar array which weighs four pounds. Limited night operations from dark to bedtime will be powered by a palm-sized nicad battery. Antennas will be half-wave slopers or quarter-wave radiators against quarter-wave counterpoises, as most of that area offers a very poor rf ground.

On-the-air operations will occur according to the following schedule, beginning as early as midday Sunday; listen for CQ NBVM from K5SBU on NBVM, SSB, and CW.

0600 CDT/1100 UT	14,235 kHz
0700 CDT/1200 UT	7,195 kHz
0900 CDT/1400 UT	14,235 kHz
1000 CDT/1500 UT	28,85 kHz
1100 CDT/1600 UT	21,385 kHz
1230 CDT/1730 UT	7,195 kHz
1500 CDT/2000 UT	21,385 kHz
1700 CDT/2200 UT	14,260 kHz
1900 CDT/0000 UT	14,385 kHz
2000 CDT/0100 UT	21,385 kHz
2100 CDT/0200 UT	14,260 kHz

The first Texas NBVM station, Bob W5GEL (W5BT), will be on frequency to coordinate, as his time allows. We would be pleased to QSO with any mode and will listen carefully for other QRP stations and DX stations. All NBVM stations should be prepared to tape-record QSOs; send the tape with your QSL. If we can find our tape of the QSO, it will be recorded on the blank side of your tape and returned.

The signal from K5SBU will be very weak, so tune slowly. Ten minutes after the schedule time, if we do not have a QSO, we may QSY to the QRP CW calling frequency for that band (60 kHz up from the bottom of each band). QSL to address below.

WAYNE GREEN'S LAIR

I found this editorial, *Wayne Green's Lair* (*VHFER*, Vol. 1, No. 5, September, 1963, Comaire Electronics, Ellsworth MI), written some time ago by Doug DeMaw (Senior Technical Editor, ARRL) and thought you might be interested.

Wayne Green's Lair

The trip would not be complete without a visit to "73 Acres" in Peterborough, N.H. Never before have we been greeted with such hospitality and friendliness. No one should sojourn through N.H. without meeting this dedicated man, his wife, and his staff, who have completely thrown themselves into the cause for improved amateur radio conditions. We enjoyed our overnight stay at W2NSD. A personally prepared waffle breakfast, by the "Ed." himself, with New Hampshire pure maple syrup and all the trimmings and garnished with a vigorous discussion related to the controversial matters of the day (which are destined to affect all ham radio operators) was very invigorating.

For many months I have tried to understand this man Green's motives and his attacks on other publishers and organizations, but until I met this guy face to face, I could not properly evaluate his thoughts. I am convinced through seeing the results of his publishing house efforts, listening to his explanation of his convictions, and hearing him relate his hopes for the ham fraternity and its future, that he is neither vindictive nor radical. He believes in what he is doing, and is willing to fight for those who share his beliefs.

Wayne's empire includes a mountaintop location a few miles distant from his main facility, which is composed of numerous sky wires, a farm house and a magnificent 125' tower supporting 96 elements on 2 meters. Along with all this, a mountain of radio gear reposes in the "shack" and is presently being assembled into operating positions of one kW denomination for all bands.

All in all, we were mighty glad to meet Wayne, his charming XYL, and staff. They are truly a wonderful group. Don't miss stopping at Peterborough when you are in that area.

I have been reading your magazine since its beginning, and I even went on the *73* trip to Europe. I still think you are one of the good guys.

GUATEMALA '76

One of my favorite pastimes is handling traffic from the nets as fast as I am able. Although the messages that are handled are of the health and welfare type, there is a certain amount of satisfaction which one gains in being able to deliver the message in the least amount of time. Until recently, the practice did not appear too important, but after several proddings by my fellow hams on various nets, I agreed to jot down the details of the contact that took place during the Guatemala earthquake in 1976.

Without any doubt, a major part of the credit for saving lives and organizing the rescue effort during the disaster is due to that very fine group of amateurs that carried the greatest load in and around Guatemala City. Our efforts at the time were devoted to assisting wherever we could and fitting into any circumstance where help was needed. For a time, the traffic was picked up from the Interstate Net on seventy-five in the evening and relayed to the Guatemala City stations the first thing the following morning. Many nets were utilized to ensure the most expeditious handling of the traffic.

During this time, not very many minutes passed when there was a lack of traffic. On February 14, 1976, an amateur station in Peru, OA4CYC, called. It seems that Maria OA4CYC had tried for several days to secure information on two sisters in Guatemala City and had probably monitored the traffic being passed on to the Guatemala City station, TG9DF, which she was unable to hear. After gaining our attention and the verification of callsigns, Maria asked for our help.

After trying for the previous three days by telephone and wire services, Maria wanted to know if it would be possible to secure health and welfare information on the two sisters who were in Guatemala City. On securing the details from Maria in Peru, the information was relayed immediately to Don TG9DF. He recognized the location where the two sisters were, or would be, in the city and indicated that he would try to reach that point via the local telephone system. In less than five minutes, Don had the answer for Maria: "The two sisters were not injured, were feeling fine, and were working hard."

That message was relayed to Dayton OH and then to OA4CYC in Peru within eleven minutes of the moment the message was

received. This was amateur radio in action, and a small example of the real-life drama that can occur.

This short experience of mine would not even have been in print had it not been for my friends and fellow amateurs who pointed out that the benefits afforded by amateur radio would be far greater if the story was put in print.

Paul Weigert, Jr. W8TH
Centerville OH

NEEDED LESSON?

I had no complaints about Bill Pasternak's Looking West column until now, but since he went over to the Int'l HFers Headquarters and was baptized, it seems to me that he may be needed more in their Fox Tango Newsletter than in *73*. These people haven't changed a bit—they still espouse and promote illegal, scofflaw bootlegging outside of the CB band. But I guess even Pasternak is no exception—California is a veritable hotbed of illegal activity—must go along with the kook philosophies prevalent out there in the Land of the Cults.

CB neighbors of mine are in receipt of several letters from various printing callbooks (phoney calls and first names only, of course) and operating QSL card bureaus out of PO boxes. For anywhere from two to ten dollars, you can get a 2 Echo, 19 Whiskey, TCN66, or whatever happens to be in vogue at the moment, plus your QSL cards forwarded to your QTH monthly! Neat.

What I can't understand is how some of them can "guarantee" that the FCC will leave them alone "if they use their Echo call and only operate on certain frequencies." Another club claims that they have "advance notice" when the FCC is going to appear in a given area! Is the FCC really cooperating with these bandits?

Another thing I fail to understand is why the FCC can't seem to find these people, even though the same ones are on the air every day, day in and day out, and talk for hours! Even an idiot could drive up to their door with a simple receiver with no S-meter!

At least (so far) most of the nitwits have had the good sense (or are afraid) to stay out of the 10-meter ham band. But I'd like to see the FCC legalize 27.4 to 28.0—*then* "superior" ones would surely move into ten. There is a certain type of CBer who just *has* to operate illegally, even if there's no reason to. This type will eventually take over and ruin what's left of ham radio.

Frankly, I'm hoping that WARC '79 will give all our ham bands to the minority countries. It might teach the whole damned bunch of us a much-needed lesson!

ASHAMED

This isn't really a letter to the editor, but I thought you should know that Stan Jopek K2JQT passed away on April 13, 1979. Stan was 40 years old and in excellent health, but he had a sudden fatal heart attack. He leaves his wife, Joan, and four teenage children. Stan was very active on six meters in the past, and was more active recently on 2 FM as the owner/operator of the .07/.67 repeater in Fredonia NY.

As tragic as Stan's sudden death was, subsequent events were repulsive, and they were the reason for this letter. One day after his death, while the family and friends were at the funeral home, someone broke into the .07/.67 repeater site and stole the entire machine and backup systems. The total value of the loss was over $3800.

What I find most repulsive in this is that the theft had to have been done by hams. The .07/.67 repeater was located in a remote area, and very few people even in amateur circles knew its exact location. It was located in a building along with several other commercial repeaters and transmitters which were much more valuable, less traceable, and much more portable. These units were not touched. The thieves were thorough. They even searched out the manuals for the 2-meter gear and took them also; they pig-tailed off the power leads, took the input tags for identification, and even taped up the leads to the standby batteries.

A four-wheel-drive vehicle was used, and at least two people carried the 6' high 19" rack over the muddy ground to the vehicle. The theft is being investigated by the Chautauqua County Sheriff's Department, and any information should be forwarded to them at (716)-672-5151. The Spectrum 1000 serial number is 0219.

I feel confident that a theft of this magnitude and perfidy will be solved. I only hope that the persons responsible are apprehended by the authorities rather than members of the repeater club. This is the first time I've ever really been ashamed of being a ham.

Ron Warren WA2LPB

Social Events

from page 130

hope to arrange special licenses for visiting hams who may wish to operate from XE1-land during their stay. There will be a flea market and demonstrations at the convention hall. For more information, contact the Radio Club Leon, PO Box 12A, Leon, Guanajuato, Mexico.

ESSEX MT
JUL 21-22

The International Glacier-Waterton Hamfest will be held on July 21-22, 1979, at the Three Forks Campground, ten miles east of Essex, Montana, on US Highway 2. Registration is at 9:00 am. Talk-in on .52 and .34/.94. For more information, write Glacier-Waterton Hamfest, PO Box 2225, Missoula MT 59806.

EUGENE OR
JUL 21-22

The 4th annual Lane County Ham Fair will be held on July 21-22, 1979, at the Oregon National Guard Armory, 2515 Centennial Blvd., Eugene, Oregon. Registration is $3.00, and an extra drawing ticket is given with advance registration. There will be displays, lectures, contests, swapshop, transmitter hunt, and entertainment. The facilities provide plenty of free parking for motor homes and trailers.

For information and advance reservations, phone or write Wanda or Earl Hemenway, 2366 Madison, Eugene OR 97405 at (503)-485-5575.

PITTSFIELD MA
JUL 21-22

The NoBARC Hamfest will be held on July 21-22, 1979, at Cummington Fairgrounds, Pittsfield, Massachusetts. There will be tech talks, demonstrations, and dealers. Flea market admission is $1.00. Advance registration is $3.00 single and $5.00 with spouse, and $4.00/$6.00 at the gate. Gates open at 5:00 pm on Friday for free camping. Talk-in on 146.31/.91. For reservations, contact Tom Hamilton WA1VPX, 206 California Ave., Pittsfield MA 01201.

GOLDEN CO
JUL 22

The Rocky Mountain Radio League, Inc., will hold its Field Demonstration Day and Swapfest on July 22, 1979, at the home of Karl Ramstetter WA0HJZ, which is located on Highway 93, Golden Gate Canyon Road. This is accessible by going one mile north of the city limits of Golden, turning westward off Highway 93 onto Golden Gate Canyon Road, proceeding for approximately 7½ miles, and making a right turn across the cattle guards. Signs will be posted for further directions. There will be demonstrations, including slow-scan TV and computers, door prizes, and a potluck lunch, with soft drinks and ice supplied by the League. It would be appreciated if everyone would make his contribution to the potluck lunch by bringing his favorite dish and helping out the League with any spare blankets and chairs. There will be camping facilities available for campers, trailers, mobile homes, etc., on Saturday afternoon before the Fest. No dogs, guns, or motorbikes, please.

MARSHALL MO
JUL 22

The Indian Foothills Amateur Radio Club will hold its 4th annual hamfest on July 22, 1979, at the Saline County Fairgrounds, Marshall, Missouri. Tickets are $2.00 each or 3 for $5.00 in advance; $2.50 at the door. Registration is at 8:00 am, with lunch at 11:30 pm (all you can eat) and the drawing at 2:30 pm. Prizes include a Tempo S1, a DenTron Jr. Monitor™ tuner, and many more. There will be flea markets for the OM and XYL. There is no charge for flea market tables this year, but reservations are requested. There will also be old and new equipment displays, a 10-X booth, and other activities for the XYLs. Talk-in on .52, .28/.88, and 147.84/.24. For information and tickets, write Norman Gibbins WB0SZI, 692 North Ted, Marshall MO 65340.

SHEBOYGAN WI
JUL 22

The annual Lakeshore Swapfest and Bratwurst Fry will be held on Sunday, July 22, 1979. Events include prizes, a flea market, an auction, and manufacturers' displays. Admission is $1.00. Talk-in on .66/.06. For further information, contact WB9NRM at (414)-457-3203.

BELVIDERE IL
JUL 22

The Big Thunder Amateur Club will hold its annual hamfest on Sunday, July 22, 1979, at the Boone County Fairgrounds. The fairgrounds are located one mile north of Belvidere on IL-76. Talk-in on .52 simplex. Donations are $2.00 at the door. Advance tickets are $1.50. For information and tickets, contact Michael Santucci WD9JGH, 862 Ivy Oaks Rd., Caledonia IL 61011.

MACKS INN ID
JUL 27-29

WIMU (Wyoming, Idaho, Montana, and Utah) will hold its 47th annual hamfest on July 27-29, 1979, at Macks Inn, Idaho. Festivities include 2-meter hunts, OSCAR demonstrations, ladies' crafts, and a repeater display. The pre-registration prize will be a Wilson Mark II handie-talkie complete with touchtone™, battery pack, and charger. The grand prize is your choice of an Icom IC-211 or a Kenwood TS-520. Saturday night special events include kids' movies and an adult dance. For further information, contact Dave Hunting WB7FGV, Box 662, Kemmerer WY 83101, or call (307)-877-9440.

MOOSE JAW SASKATCHEWAN CAN
JUL 27-29

The Moose Jaw Amateur Radio Club will hold its 1979 Hamfest (Particifest 79) on July 27-29, 1979, at the Saskatchewan Technical Institute, 600 Saskatchewan St. W., Moose Jaw, Saskatchewan, Canada. Registration will be held on Friday evening with a full day of activities on Saturday culminating in a banquet and dance. Most of the meetings and workshops will be held on Sunday. There will also be a busy schedule for the XYLs.

OKLAHOMA CITY OK
JUL 27-29

The Central Oklahoma Radio Amateurs will sponsor the Oklahoma State ARRL Convention and "Ham Holiday" on July 27-29, 1979, at Lincoln Plaza, 4445 Lincoln Blvd., Oklahoma City, Oklahoma. The program will include an ARRL forum and technical talks on 1-GHz techniques, fast-scan TV for radio amateurs, NBVM, and other subjects of current interest. In addition, a full program is scheduled for the ladies. Pre-registration will be $4.00 if received before July 20. After that date, it will be $5.00. A synthesized 800-channel VHF transceiver will be awarded to encourage pre-registration. The main award will be a TS-120V with power supply. Adequate rooms are available for commercial exhibitors and swappers. Mail your registration to CORA, PO Box 14424, Oklahoma City OK 73113.

Unlimited parking space is also available.

OLIVER BC CAN
JUL 28-29

The Okanagan International Hamfest will be held on July 28-29, 1979, at Gallagher Lake KOA Kampsite, 8 miles north of Oliver, B.C., Canada. Registration starts at 9:00 am Saturday. Activities start at 1:00 pm Saturday and continue until 2:00 pm Sunday. Ladies may bring their hobbies and items for a white-elephant sale. Featured will be prizes, a flea market, bunny hunts, entertainment, a home-brew contest, and more. A potluck lunch will be served Sunday at noon. Call-in on 3800, .34/.94, and .76 simplex. For information, write John Juul-Andersen VE7DTX, 8802 Lakeview Dr., Vernon, B.C., Canada V1B 1W3, or Lota Harvey VE7DKL, 584 Heather Rd., Penticton, B.C., Canada V2A 1W8.

BOWLING GREEN OH
JUL 29

The Wood County Amateur Radio Club will hold its 15th annual Wood County Ham-a-Rama on July 29, 1979, at the Bowling Green Fairgrounds, Bowling Green, Ohio. Gates will open at 10:00 am, with free admission and parking. Dealer tables and space are available. Trunk sale space and food will also be available. Tickets are $1.50 in advance and $2.00 at the door. Prizes will be awarded. Talk-in on .52 K8TIH. For information, write Wood County ARC, c/o Eric Willman, 14118 Bishop Road, Bowling Green OH 43402.

NASHVILLE TN
JUL 29

The Radio Amateur Transmitting Society (R.A.T.S.) of Nashville, Tennessee, will sponsor the Nashville Hamfest on Sunday, July 29, 1979, at the National Guard Armory on Sidco Drive, in Nashville, Tennessee. Tables, bargains, and refreshments are available, as well as prizes. Admission is $3.00. Talk-in on .90/.30. For more information, contact Richard Wagner K4MZE, 1015 Haber Drive, Brentwood TN 37027, or phone (615)-794-5356.

BALTIMORE MD
JUL 29

The Baltimore Radio Amateur Television Society (BRATS) will be holding the annual BRATS Maryland Hamfest on Sunday, July 29, 1979, at the Howard County Fairgrounds, Rtes. 32 and I-70, 15 miles west of Baltimore, Maryland. The event, beginning at 8:00 am rain or shine, includes a giant flea market, indoor and outdoor exhibit areas, top prizes, and plenty of good food and refreshments. Tickets are $2.00, tailgating is $2.00, and tables are $4.00 in advance, $5.00 at the

Continued on page 204

from page 182

door. Talk-in on .16/.76, .63/.03, .52/.52, and 52.525. For information, contact BRATS, PO Box 5915, Baltimore MD 21208.

IRVING TX AUG 3-5

Encounter '79, the Texas VHF-FM Society's 1979 Summer Convention, will be held August 3-5, 1979, at the Villa Inn, Irving, Texas. Activities include a transmitter hunt, flea market, FCC exams, manufacturers' exhibits, hospitality room, and several programs and forums. Talk-in on 146.52 and repeaters in the area. Pre-registration is $5.00 until July 1. Registration at the door is $6.00. For information, write Encounter '79, PO Box 3608, Arlington TX 76010.

FLAGSTAFF AZ AUG 3-5

The Amateur Radio Council of Arizona will hold its annual Ft. Tuthill Hamfest on August 3-5, 1979, at Flagstaff, Arizona. Prizes include TS-520 transceivers, a microwave oven, a Wilson Mark II HT, a Wilson System III triband antenna, and more. Featured will be a western barbecue, tech sessions, and exhibits. Camping facilities are also available. For further details or information, write Ft. Tuthill Hamfest, c/o 8520 E. Edwards Ave., Scottsdale AZ 85253.

LITTLE ROCK AR AUG 4-5

The Central Arkansas Radio Emergency Net (CAREN) Amateur Radio Club will hold its second annual Ham-a-Rama on Saturday and Sunday, August 4-5, 1979, at the Arkansas State Fairgrounds, Little Rock, Arkansas. There will be two main prizes given, as well as door prizes. Featured will be forums, dealers' exhibits, a Saturday night party, and a large flea market. Talk-in on 146.34/.94. For details, send an SASE to Morris Middleton AD5M, 19 Elmherst Drive, Little Rock AR 72209.

REND LAKE IL AUG 5

The Shawnee Amateur Radio Association Hamfest will be held on August 5, 1979, at Rend Lake in southern Illinois. Complete camping and recreational facilities will be available, so plan to spend the weekend at the lake and attend the hamfest on Sunday. Family activities are planned. Hourly door prizes will be awarded. There will be no charge to vendors. For information, contact WB9ELP or WB9SWG.

PITTSBURGH PA AUG 5

The South Hills Brass Pounders and Modulators will hold its 42nd annual Pittsburgh Hamfest on August 5, 1979, from noon until dusk at the Allegheny County Community College south campus on Rte. 885, 2 miles south of the Allegheny County Airport and approximately 15 miles southeast of Pittsburgh, Pennsylvania. Advance registration is $1.50; $2.00 at the door. There will be a large indoor air-conditioned area for vendors and the flea market, and a large paved surface for the outdoor flea market. There will also be prizes and food. Talk-in on 146.13/.73 and .52/.52. For information and preregistration, write Bruce Banister, 5954 Leprechaun Dr., Bethel Park PA 15102.

MT SINAI LI NY AUG 5

The Radio Central Amateur Radio Club will hold its "Ham-Central" on Sunday, August 5, 1979 (rain date is August 12, 1979), at the Mt. Sinai Elementary School, Rte. 25A, Mt. Sinai, Long Island, New York. Admission for sellers is $3.00 per tailgate space and $1.50 for buyers, with XYL and children under 12 free. Monies are to be used for Radio Central and the St. Charles Hospital Repeater. Doors will open at 7:00 am for sellers and 9:00 for others. They will close at 4:00 pm. Featured will be antenna advice with Art and Madeline Greenberg, a Novice table, great food, a CW contest, an ARRL table, a special event of a fly-in by the Suffolk County Police Dept. helicopter, and a Radio Central Club table. Talk-in on 146.52 WA2UEC and 144.71/145.31 K2VL. For information, call Joan Longtin at (516)-924-8438 or Robin Goodman at (516)-744-6260, or write Radio Central, "Ham-Central," PO Box 680, Miller Place NY 11764.

JACKSONVILLE FL AUG 4-5

The Jacksonville Hamfest Association is pleased to announce the 1979 Jacksonville Hamfest and ARRL North Florida Section Convention to be held on August 4-5, 1979, at the Jacksonville Beach Municipal Auditorium, Jacksonville, Florida. The location is just one block from the beach, where U.S. 90 meets the sea.

Advanced registrations are available at $3.00 per person from R. J. Cutting W2KGI/4, 303 10th St., Atlantic Beach, Florida 32233. Price at the door will be $3.50.

A large indoor swap area will be featured, with advance table reservations available for $5.00 per table per day from Robbie Roberts KH6FMD/W4, 10557 Atlantic Blvd., #31, Jacksonville, Florida 32211. Information on exhibitors' booths and space are available from the same address.

Other features and programs include statewide organization meetings on such topics as traffic nets and MARS, a microprocessor seminar, a solar power demonstration, a DX "pileup" contest, a hidden transmitter hunt, an OSCAR forum, ARRL forums, emergency preparedness programs, DX and contest presentations, antenna and technical seminars, and much more.

More general information may be obtained from JHA, 911 Rio St. Johns Dr., Jacksonville FL 32211.

SALEM OH AUG 5

The second annual Salem Area Hamfest will be held on August 5, 1979, from 9:00 am to 3:00 pm at the Kent State Salem campus, Salem, Ohio. Tickets are $1.50 in advance and $2.00 at the door. Inside tables are $5.00 with space for your own table at $2.00. Flea market space is $1.00. There will be air-conditioning, a wheelchair ramp, free parking, refreshments, and prizes, consisting of an Atlas RX-110, TX-110, and a PS-110. Talk-in on 146.52. For details, write Harry Milhoan WA8FBS, 1128 West State, Salem OH 44460.

AMARILLO TX AUG 10-12

The Panhandle Amateur Radio Club will hold its sixth annual Golden Spread Hamfest and Convention on Friday, Saturday, and Sunday, August 10-12, 1979, at The Inn of Amarillo, 601 Amarillo Blvd. West, Amarillo, Texas. The format consists of two full days of exhibits and trading, six technical sessions, programs for the ladies, valuable door prizes, Army and Navy MARS meetings, ARES meeting, an ARRL forum, and plenty of free parking. Displays may be set up any time after 1:00 pm on Friday, August 10th, at a fee of $20.00 per table. For information, write Hamfest, PO Box 10221, Amarillo TX 79106, or phone Jay Ledbetter WB5UBM at (806)-376-6042 (nights and weekends) or Chuck Passmore WB5BRC at (806)-372-1631.

NOTE to 73 Subscribers

From time to time 73 Magazine makes its subscriber lists available to carefully-screened companies and organizations whose products, services or information may be of interest to you. In every case, we must approve all organizations wishing to mail to our subscribers. In every case they receive a list of names and addresses only—no other information we may have is divulged. Each organization may use the list only once and agrees never to make any personal or telephone solicitations from it.

The overwhelming majority of our subscribers appreciate this controlled use of our mailing lists—it helps them shop conveniently by mail for products and services they need, often at substantial savings. A few people prefer their names not be used. It is to them we address this message.

If you do *not* wish to be a part of this service, please complete the form below . . . your name will not be used in this manner for any reason.

(If you asked us in the past to remove your name from our lists, there is no need to repeat the request.) Please allow about six weeks for your request to take effect.

☐ I wish to have my name removed from the list of subscribers receiving mail other than the regular subscription to 73 Magazine.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

DXING AGAIN

It's been a long time since I've been on twenty meters seriously seeking out DX. I got heavily into this back in the mid-60s. Then I got into FM and repeaters . . . and there really is only so much time a week I can spend on hamming. Next came enthusiasm for slow scan . . . another incredible user of hamming time . . . and also a lot of fun. Then I got into OSCAR, and boy, does that take a lot of time and work . . . and is also immensely rewarding with fun.

A couple of years ago, I decided it was time to poke into the newly developing sunspot cycle and get some DXing done. I had a Tech working at the magazine at the time and I wanted him to refurbish our beam . . . which resulted in his totally destroying both the beam and the tower. It sure was exciting when it crashed down!

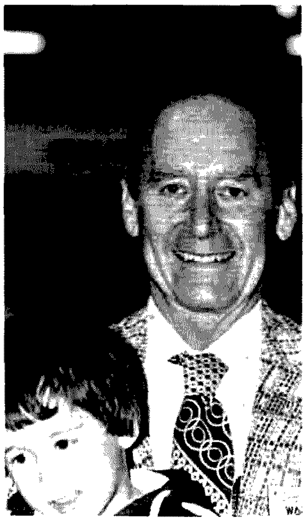
Anxious to get going, I started dickering for a new tower. Several tower firms responded favorably to my offer to swap some ad space for a new tower. One firm was super hot on this and wanted me to put up their newest and biggest crank-up system. They weren't able to get things going in time for the job to be done before the 1977-78 ice age settled in up here, so we planned on setting it all up in the spring of 1978. Then they kept putting me off with vague promises and delays for an entire year. I finally gave up on them and got a tower almost immediately from Rohn . . . bless 'em. This one arrived the day before the ground froze solid for the winter.

The tower is now up and working, complete with a Wilson tribander antenna. I finally got a rig hooked up to it the other day and found out something which I hadn't realized . . . most of the modern-day rigs don't put out enough soup to drive my old Henry 2K amplifier to anywhere near full output. I had that trouble years ago with my Central Electronics 200-V exciter. It takes about 300 Watts or so to hit the 2K hard enough to push it to 1,000 Watts average output.

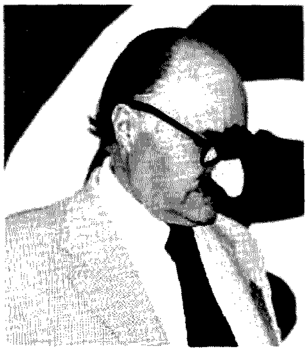
Even with only about 400 to 500 Watts registering on the Bird Wattmeter, I found the new station to work extremely well. There is an initial psychological handicap when I am not running a full gallon . . . I know I am up against 5-kW and 10-kW competitors in the pileups and I don't go in with the confidence I might otherwise have.

My first call was to FM7WE on Martinique, which used to be relatively rare. Guy came back the first try and gave me a nice report. The distance wasn't amazing, but my ability to shoulder my way through a medium pileup was impressive. No sooner was I finished talking with Guy than I tuned up a few kHz and heard VP8RX in the Falkland Islands trying to con-

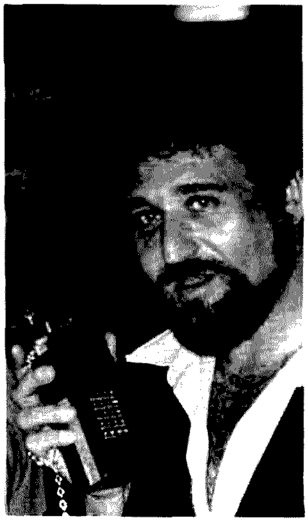
SCENE AT DAYTON



Howard Furst W6PHA runs Global Importing and sells keyers and a lot of other interesting gadgets. Seen here with his junior op, Howard also is a lawyer practicing before the FCC . . . and an old friend.



Who is this mysterious and handsome stranger? Could it be The Long Ranger? Superham? Or might it even be legendary Larson E. Rapp WIOU? Dayton was agog.



Marv Druskoff of Yaesu created quite a stir at the Dayton Hamvention with his prototype synthesized rig. He had it chained to his belt to make sure that there was no way to mislay the unit. Programmable.

DX

Chuck Stuart N5KC
5115 Menefee Drive
Dallas TX 75227

Hard as it is for us to believe, 10 months have passed since this column first appeared in these pages. At that time we had high hopes and a lot of ideas as to what would make an interesting DX column.

Most of those hopes have been realized, and from the mail we receive, many of you find our efforts worth reading each month. Credit goes to all of you who have written or called with information, suggestions, and comments. Without a constant flow of news, rumors, gossip, and facts, there would be no column. Thanks to all of you and keep those cards and letters coming, folks.

SLIM

Many of you have written in wondering just who is this Slim character we keep mentioning. Slim was invented by Hugh Cassidy WA6AUD, editor of the weekly *West Coast DX Bulletin*, as a personalization for pirate, phoney, etc. Any illegal operator is called Slim.

It began in 1968 when a station showed up signing 8X8A, giving his QTH as Cray Island and his name as Slim. Cray Island was supposed to be a newly-formed volcanic island just south of Iceland that would definitely count as a new one. Although most everyone was taken in, it soon became apparent that this was just another pirate operation when Slim's designated QSL manager denied any knowledge of the operation.

From that time on, any illegal operation has been said to be the work of Slim. Slim has operated around the world since first appearing in 1968. You've probably worked him sometime yourself, for Slim is everywhere.

HEARD ON THE BAND

The OE6XG/A group ran off some 13,800 contacts from Abu Ail despite generator problems. QSL to WA3HUP with SASE, etc. Financial contributions to help offset the several thousand dollars spent by each member of the group would be appreciated.

3B8CF, 3B8CD, and 3B8DA all hold licenses for 3B6, Agalega, and visit the island regularly to maintain the radar and weather-monitoring equipment.

While we're in the area, 5R8AN has been active Mondays and Thursdays from 1900Z on 14345 kHz. QSL to K4IE.

VK9NI on Norfolk Island runs a daily sked to Europe on 28585 kHz from 0900Z to 1100Z. He listens for stateside Sundays on 28900 kHz after his 0001Z sked with W6EDN. QSL to PO Box 290, Norfolk Island, via Australia.

KA1IW plans to keep the following schedule until his August 15 departure from Ogasawara Island: 3797 kHz from 1200Z to 1300Z, 7064 kHz from 1130Z to 1200Z, 14285 kHz from 1000Z to 1130Z, 21365 kHz from 2330Z to 0100Z, and 28550 kHz from 2300Z to 2330Z. QSL to K8DYZ.

You CW fans can find HS1ABD most days near 14030 kHz from 1400Z and around 3515 kHz from 0300Z. QSL to K3EST.

If you are confused by the UK8 callsigns, the following list should help to ease your pain. UH8 is UK8B/E/H/Y. UJ8 is UK8J/R/S. UI8 is UK8A/C/D/F/I/L/O/T/Z. UM8 is UK8M/N/P/Q. Now look back through your log to see how many new ones you worked without knowing it.

KC6AT in the Western Carolines is active regularly around 14285 kHz from 0800Z. QSL to Box 490, Koror, Palau, WCI 96940. SASE, please.

KV4AA's record of 48,100 QSOs in a single year will go into the *Guinness Book of World Records* unless someone can prove a higher total. If you can, contact Frank Anzalone W1WY.

Although you might be getting a late start, a prize of a holiday for two to the Isle of Capri will be awarded to the amateur making the most contacts with Naples, Italy, from now to December 31, 1979. Logs must reach Box 336, 180100 Naples, Italy, by January 31, 1980.

N4XX offers a free copy of the *Shortwave Propagation Handbook* to anyone helping him obtain a valid QSL for 10-meter contacts with 5A1TG (December, 1957) and/or 5A4TT (January, 1958).

Business Week magazine of May 7th had a very interesting article on WARC 79. They note that some of the lesser-developed countries are already on record as planning to demand and get everything in sight. They draw a parallel to one of the ITU conferences a few years back when some totally land-locked countries demanded and got maritime frequencies. The results of WARC 79 will have a strong effect on amateur radio for years to come.

The Jersey ARC club station, GJ3DVC, operated by GJ4HSW, can usually be found on 21300 kHz Fridays from 1800Z and on Sundays from 0930Z around 14270 kHz.

5T5CJ looks for stateside daily during the week on 28525 kHz from 2100Z to 2200Z. He also seeks stateside contacts via OSCAR 8. QSL to W4BAA.

OH2BH is mounting a massive effort to activate Mt. Athos this summer. A whole new generation of DXers has come into being since this rare spot was last heard.

The following Americans are active with the peace-keeping forces in the Sinai: Rich WD4SCJ/SU, Ed K5AON/SU, Ken WB5BXQ/SU, Ed W5PYW/SU, and WA7JRL/SU. They have 10,000 QSLs printed and waiting to be filled out at ESY-SFM, PO Box 21, FPO NY 09527. SASE, please.

Congratulations to the first officers of the newly-formed South Florida DX Association: Joe Plcior WB4OSN, President, Norm Alexander W4QQN, VP, Rob Robinson W2SR, Secretary, and Vic Dubois N4TO, Treasurer.

The QSLs for the K4YT/5R8 operation are not being accepted for DXCC credit, unauthorized operation being the reason given.

The Caribbean Net on 14175 kHz at 1100Z is a good place to snag some of the more rare types in that area. A recent roll call was answered by VP2A, VP2D, VP2K, VP2L, J3, J6, 6Y5, 9Y4, HI8, VP2M, VP2S, 8R1, C6, HK, HC, HS, 9M2, CO, 9M6, 9V1, VS5, YJ8, DU, YB, VR1, VR6, H44, 3D2, VK9, ZL, UA, JD1, 4S7, BV2, T2, FB8Z, A51, KX6, and KA1. Actually, some are rather far removed from the Caribbean area, but you get the idea.

A9ZEX was a special call used at the Middle East Communications Faire. QSL to the A9 Bureau.

The March Norfolk Island operation by HB9AAA netted some 5500 QSOs covering 112 countries. Cards were mailed in April.

The Bangalore Radio Club in India meets most days on 7090 kHz at 0730Z.

We have reported in the past on the advantages of enclosing IRCs, mint stamps, dollar bills, etc., when requesting QSLs direct from overseas QSL routes. We also made a point of suggesting that it is usually best to follow the directions of the DX station himself. Now along comes PY1APS with a new request concerning his recent PY0APS operation from Fernando de Noronha. Gerson says to skip the IRCs, stamps, etc., and send computer programs instead. Seems he has a new Radio Shack TRS-80 microcomputer with 16K Level II BASIC and he needs programs to use with his new computer. If you have any programs you want to share, you can send them to Gerson Rissin, PO Box 12178 Copacabana, 20000 Rio de Janeiro, RJ, Brasil.

XT2AW is a new operator in the Voltaic Republic. His name is Harold and you can QSL to Box 2332, Ouagadougou, Voltaic Republic.

The newly-formed Bangladesh Amateur Radio Club is in need of service manuals for Hailicrafters SBT-20 crystal-controlled transceivers. If you can supply information on these units, contact K1ZZ at ARRL Headquarters.

Bob Geary 5Z4NH, a DX Profile of a few months back, has left Kenya after 13 years and is returning stateside.

Congratulations to new Radio Club of America members Jim Fisk W1HR, John Knight W6YY, and Bill Vette K6TXR.

One of the side benefits of the recent 1S1DX operation from Spratley Island was the 16,000 plus QSOs the group handed out from VS5, Brunei, and some 3,000 from VS6, Hong Kong. The main Brunei operation by N2OO was from VS5MS's QTH. Gear used was a FT-901DM barefoot and a TH6DXX at 65 feet. Even with all the problems that developed, some of the group are planning another trip to Brunei. The following list should help to locate the correct QSL route for the station you worked. VS5AR and VS5M to N4GG. VS5SW to K4SMX. 1S1DX, VS5ZR, and VS5JB to VK2BJL. VS5OO, VS5MS, VS5KV, and VS6AK to N2OO. Be sure to enclose the usual SAE or SASE. The group is still in debt for the trip and, should you be so inclined, support can be directed to the South Jersey DX Assn., 33 Shore Drive, Manahakin NJ 08050.

There is apparently a new low-power AM license class in Russia, having a code-free exam and aimed at the younger set. The class is identifiable by the EZ prefix. While in Russia, we might mention that the looked-for 160-meter authorization came through in March. Maximum power is ten Watts in the 1850 kHz to 1950 kHz band. Subbands are 1850 to 1875 for CW, 1875 to 1900 for CW and SSB, and 1900 to 1950 for CW/SSB/AM.

If you are among the many thirsting for a Dodecanese contact, check 21345 kHz on the weekends after 1330Z. SV5JH hangs out in that area, or so the story goes. QSL to DJ9ZB.

LU3ZY in the South Sandwich group has been quite regular on both 40 and 15 CW.

Newhall CA 91321

Something great happened recently in San Diego, California—score one for amateur radio! San Diego amateurs have won a major victory in the realm of tower height ordinances. This is bound to have a lasting effect on communities throughout this state and elsewhere. Exactly what happened, you ask? Jim Allen W6OGC of La Mesa, California, sent us this report.

WHO SAYS YOU CAN'T WIN AT CITY HALL?

"Have you heard about the new zoning code restricting ham towers to 50 feet in the county?" asked K6NA as I walked into the local radio store one Saturday late last December.

"What!!!??" was my incredulous response. Thus did I learn that the Board of Supervisors of San Diego County had, in enacting a complete revision of the County Zoning Ordinance, slipped in a "zinger" which had escaped the notice of local hams. It was to become effective on January 1, 1979, only a matter of days away.

Obviously, something had to be done. Glenn suggested I contact Sybil W6GIC, who was a delegate to the San Diego County Amateur Radio Council (SANDARC), which had begun to react. I contacted Sybil and learned that while SANDARC was hosting 7,000 visitors to the ARRL National Convention, the county had been in the process of enacting this new ordinance. Sybil suggested I contact Larry N6LY, a SANDARC officer who had been assigned the job of writing a letter protesting this ordinance to the local Department of Land Use and Environmental Regulation. She also suggested contact with our SCM, W6INI. Larry was able to give me the text of the height limitation section and a summary of the letter to LUER. He also gave me the name of the LUER employee to contact. Sybil had gone over to their office and gotten the name.

Not being technically well-trained, I have many times been the grateful recipient of help on technical problems from more technically-oriented fellow hams. Now it seemed like here was a problem that I, as a lawyer, might be able to help with. So, I offered to help in any way I could. The response to this offer of help was immediate, enthusiastic, and affirmative.

As best I could determine, the ordinance had completely escaped the attention of local amateurs in the pre-enactment consideration. The staff had not thought to seek out amateurs, and amateurs were oblivious to the revision which was only 2 sections less than one page long in a completely rewritten zoning ordinance over an inch thick.

When I spoke to the staff at LUER, I learned that the reason 50 feet was chosen was that it was a nice round number that seemed high enough to accommodate us. I promptly disabused them of that idea!

The new zoning ordinance established "height designations" for each zone which permitted building heights of between 15 and 60 feet, depending upon the area. Exceptions to the maximum height were available for, among other things, "Transmitting antennas no more than 50 feet in height used by licensed amateur (ham) radio operators." Amateur antennas in excess of 50 feet would be allowed provided a minor use permit could be obtained. A minor use permit required payment of a $200 fee, a hearing upon notice, and an environmental impact review, which, we learned, cost $250.00 and up. A more dismal prospect could scarcely be imagined.

To us, it was clear that this ordinance had been proposed and considered by people who had no idea of the disastrous impact of this type of regulation on our activities. Consequently, our first thrust was to educate.

I prepared a brief draft report explaining what amateur radio is, what we do, and how and why we do it. I also explained elementary antenna and propagation practice. The draft was reviewed by W6GIC, W6INI, N6LY, and K6NA. Many helpful ideas were considered and incorporated. In this process, K6NA and I spent many hours changing, editing, thinking out loud, arguing the merits and demerits, and banging the thing into shape. Glenn is an individual who is not only thoroughly familiar with just about every aspect of ham radio (including "hands on" experience with large, tall antennas), but also brings a good measure of practical common sense to bear on the task at hand. It is due to his creative and practical ideas that the report was brief, readable, and informative. The report included, as exhibits, FCC Regulations, Subpart A, Section 97.1, Chapter 1 of the *1979 Amateur Radio Handbook*, copies of *QST* articles dealing with emergency communications, and a representative set of plans and drawings for a well-known free-standing tower.

Armed with this, I made an appointment to see the staff member at LUER. He was at once receptive and discouraging. After listening for about 45 minutes, he said he would be happy to review the report, but felt that the prospect of LUER recommending an amendment was none too bright. A few weeks later, I heard that the Director of LUER had decided not to recommend an amendment.

Initial research had led me to the conclusion that a court challenge was out of the question. This impression was confirmed by Howard W6US, a fellow lawyer of vast experience. This was not so much a legal problem as it was a political problem.

At the January SANDARC meeting, I reported on my activities and conclusions. I had no political experience, but it seemed to me that the Board of Supervisors had to be shown that (1) this was a serious problem, (2) our reasons and proposals for an amendment were reasonable and in the public interest, and (3) our views would have considerable voter support. One way to show support would be a petition signed by county residents.

The delegates directed me to prepare a suitable petition which would be circulated throughout all member clubs. Each club member would be supplied with petition forms and asked to obtain as many signatures as possible. I immediately prepared the petition and delivered it to W6GIC, who had accepted the responsibility of getting it distributed to the SANDARC member clubs, who would print up as many as necessary for its members' needs. All petitions would be returned to me or to the delegate representing the particular club in time to be taken to the SANDARC meeting in late March.

The word was passed on local repeaters and ARES nets. Within a very short time, practically every active ham in San Diego was alerted to the situation. Announcements were made at club meetings and published in club newsletters.

Pretty soon, I could not listen for very long on the local repeaters without hearing some discussion of the county ordinance. I had hundreds of QSOs with local hams offering suggestions, asking for details, requesting more petition forms, or offering to help. Petitions were distributed to local ham equipment outlets. They were available at the swap meet, were mailed out with club newsletters, and were distributed at meetings. Some hams filled up the ones they had and asked for more.

While all this was going on, LUER changed its mind. I learned that LUER would recommend an amendment to 75 feet to the County Planning Commission, which would consider it and make a recommendation to the Board of Supervisors. While 75 feet was not what we had in mind, it was at least an opportunity to get our foot in the door, so to speak, and sell our position. The hearing was set up for March 25 at 9 am, the morning after the SANDARC meeting at which petitions were to be returned.

Along with the idea of the petition, it seemed important to have as many hams as possible attend the hearing. A large turnout supporting our position would be persuasive. Again the word was passed on local repeaters and ARES nets. Everyone who could possibly take the time to come to the hearing was urged to go.

Prior to the hearing, I had sought the advice of John K6KOI, another local attorney with experience in land use and regulation matters. He and one of his partners met me for lunch and were able to make many extremely valuable suggestions as to how to best present our position to the Planning Commission. I sprang for lunch, and it was one of the best investments I've ever made. They were intimately familiar with the Planning Commission and what kinds of arguments would be most persuasive.

At the March SANDARC meeting, the delegates passed a motion commissioning me as their spokesman. A fairly impressive stack of petitions was delivered.

The next morning, about a dozen hams and I appeared at the hearing. I gave a presentation, much shorter than planned, since the Chairman refused to allow more than 5 minutes or so, in spite of the rules which allow each speaker 3 minutes, each of whom can cede his time to a spokesman, not to exceed a total of 15 minutes.

Paul WA6GDC spoke at the hearing to relate an incident which had occurred the previous evening. Paul is active in "Happy Flyers," an organization of ham-pilots. An ELT had gone off in the mountains east of San Diego. No one on the ground had heard it. It was reported by a jet plane passing over at 30,000 feet. Search and rescue teams had been dispatched and were then combing

LETTERS

PLANNING

The ARRL's new Long-Range Planning Committee is seeking to obtain input and ideas from amateurs throughout the country. As the committee's first chairman, I have prepared the attached "open letter" to US amateurs to solicit (via the amateur radio press) their assistance with the work of the committee. I'm hoping that you would be willing to include it in an early issue of *73*.

Victor C. Clark W4KFC
Clifton VA

Dear Fellow Radio Amateur:

For more than sixty years, amateur radio in the United States has grown like Topsy, carried along on the wave of a galloping technology, without a great deal of thought being given to its long-range future. Having established during this initial half-century an impressive record of technical innovation and a growing repertoire of services to society, we have not done too badly.

But where are we going from here, and what will be our "basis and purpose" in the years ahead? Some express concern, for example, that the character of amateur radio in this country has been moving away from the technical aspects of yesteryear—the designing, constructing, and subsequent testing of home-built equipment. If, in fact, our technically-oriented justification for spectrum occupancy is declining, there is little evidence that the impact of such a trend upon our long-range future is being given a great deal of thought. Most of us recognize that amateur radio is changing and will continue to change, for our activities are closely linked not only to a rapidly changing technological field, but also to a dynamic society that confronts us with new obstacles, challenges, and opportunities for providing useful public service.

With a steadily increasing number of new amateurs, the spectre of more government intervention, and pressures on our frequencies and erstwhile freedoms (via WARC, changes in licensing regulations, revision of the Communications Act of 1934, the growing rash of restrictive antenna legislation, RFI problems, etc.), it becomes increasingly apparent that *all* of us—ARRL members and nonmembers alike—need to give much serious thought about where the Amateur Radio Service is or should be going in the decade ahead.

Long-range planning is hardly an exact science, but it *is* possible to anticipate some problems, to perceive certain distant opportunities, and to develop appropriate recommendations. If we put our collective heads together, perhaps we can do something to establish positive courses, rather than simply drifting and reacting to external events. But it will require a substantial amount of effort on a continuing basis by a number of concerned amateurs who are willing to assess the past for the guidance it may provide in planning for the future, rather than merely criticizing past decisions or failures.

As a method of providing a focus for a long-range planning effort, the ARRL's Directors at their January board meeting created a Long-Range Planning Committee (LRPC), set aside initial funding for its operation, and gave it the responsibility of "... reviewing and making recommendations to the Board concerning the programs which the League is and should be providing to its members and to the Amateur Radio Service ..."

At its initial meeting in February, the members of the LRPC—Dick Baldwin W1RU, Hazard Reeves K2GL, Charles Dorian W3JPT, Vic Clark W4KFC, Larry Price W4RA, Jay Holladay W6EJJ, and Herbert Hoover III W6ZH (with ARRL President Harry Dannals W2HD, ex-officio)—agreed upon a number of criteria governing its activities: No facet of the ARRL's operation was exempt from scrutiny and/or recommendations; the general welfare of the entire Amateur Radio Service was to be served, not just parts of it; and a subject as complex and far-reaching as the future of amateur radio and the ARRL could not be thoroughly appraised without the input of many different people ... ARRL members or not.

Therefore, if *you* have some thoughts, comments, and/or recommendations about the future of the Amateur Radio Service and/or the ARRL in general, or some very specific portions thereof, please let the LRPC have the benefit of your thinking. A letter or card sent to me at the address given below, marked for the attention of the LRPC, will be acknowledged, and I will make sure that your comments are made available to each of the members of the committee.

Vic Clark W4KFC
Chairman, LRPC
12927 Popes Head Road
Clifton VA 22024

It is interesting to see a leading director of the ARRL admit in print that the material we have been reading in QST *about the League providing guidance for amateur radio has been hogwash. Here is the admission that there has not been much thought given to long-range problems ... which anyone who has been keeping up with events knows all too well.*

Next Vic tries to put over that old saw about amateurs not building any more. I'm sick and tired of hearing that from the League ... it is a lie and a put-down for amateurs. The fact is that more amateurs than ever before are building and designing equipment. The percentage of the magazine ads for parts is proof positive of this. Just compare the parts advertised today with the meager parts ads of the 1930s, back when hams were really hams. Utter rot. In those days the construction projects filled two very small magazines ... we print more projects in a couple of issues than you could find in a year in the olden and golden days of ham construction.

Sure we're having problems with the FCC and with WARC. We are living in a much more political world than we were forty years ago and we are stuck with a sixty-year-old organization which is still somewhere back in the '30s politically. You deal with the FCC in a political manner, not with dockets and testimony or even with lawsuits. It is time the ARRL learned this and started dealing realistically with the world of the '80s. Remember that the FCC got backed down once and once only in recent years, and that was over the repeater rules. I organized that project completely and ran it with the ARRL refusing to cooperate, saying it wouldn't work. It did work ... and nothing else has.

The ARRL has funded almost identical efforts before. The directors set aside $100,000 to be used to help preserve amateur radio. Instead, it was used as a slush fund for vacations and other nonsense. There never has been an accounting of the expenses put to this fund ... and there never will be. So here we go again.

However, despite my cynicism, take Vic at his word and give him the input he wants. Let's see if anything happens this time ... and perhaps we can find out what they ever did with the $100,000 they set aside and kept replenishing for preserving amateur radio.—Wayne.

INTRUDER WATCH

Wells R. Chapin W8GI
507 Franklin
Kingsley MI 49649

Dear OM:

Your article, "Where Have All the kHz Gone?", in the June, 1977, issue of *73* made me realize that mine was not the only voice crying in the wilderness. Reminds me of Clair Foster and Boyd Phelps too many years ago.

Now for the record: I've been licensed since 1936 and an ARRL member almost that long. My *QSTs* go back to 1934. I view with alarm the "increased expenses" of this non-profit organization that requires all too frequent raises in dues. I view with alarm the high pay of the top management people in Newington and their all-expenses-paid junkets to overseas conferences, along with wives or secretaries. I view with alarm the loss of dedicated staff along with the "necessary" building addition.

I wonder about all those fine "services" provided to the membership. (My own attempt, once, to utilize their "Technical Information Service" was a disaster.) I wonder about their vaunted "Intruder Watch," which you mention.

Let me tell you about their "Intruder Watch." Two years ago, I was home recovering from an operation, so I scanned all the HF bands during the day to see what was going on, just as I did in 1938 when I was also home for reasons of health. The comparison in daytime ham activity between 1938 and 1977 was astonishing—the HF bands are *less* crowded now! It made me wonder about the great "band crowding" claimed by the ARRL.

But, getting back to the "Intruder Watch," I discovered during the day very strong Russian language *AM* nets, sometimes two or three, on frequencies around 3550 and 3650 kHz in our 80-meter CW band. These obviously were the foreign fishing boats right off the coast of Long Island, and they could be *seen*. This was before the 200-mile law went into effect.

Contests

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

DAFG 10 METER CONTEST
Contest Period:
1200 to 1600 GMT
August 4, 1979

Note: This contest started In May, 1979, but information was received too late for entry in the contest calendar. This is therefore the second and final part of the test.

EXCHANGE:

RST, QSO number, name, QTH.

FREQUENCIES:

28075 to 28175 MHz, RTTY only!

SCORING:

Each station may be worked once. Each complete two-way RTTY contact counts as one point. The multiplier is determined by the number of countries worked. The European Country List (WAE) and the latest ARRL Country List will be used. In addition, each different prefix will be considered as a multiplier, too. The final score will be a total of the multipliers multiplied by the total of QSO points.

CLASSIFICATIONS:

Class A—up to 100 Watts output; Class B—above 100 Watts output; Class C—SWL.

LOGS AND ENTRIES:

Logs must contain name, call, and complete address of participant, class, call of station worked, complete exchange sent and received, country, final score, and time in GMT. Logs without final score will be considered check logs. SWLs—for points, multiply and score same as above. The same station may be reported a maximum of 5 times. Instead of exchange received, report call of station worked. Your log should be in the hands of the manager no later than 30 days after closing the test. Address entries to: Klaus K. Zielski DF7FB, PO Box 1147, D-6455 Erlensee 1, West Germany. Awards to the highest-scoring SWL and first five in each class.

BARC COMMEMORATIVE STATION

The Bancroft Amateur Radio Club will be operating a special commemorative station, XJ3TBC, 24 hours a day during the centennial "Homecoming Week" of August 11 to 18 from the Centennial Headquarters. CW and phone operation on all HF bands except 160 meters, VHF on 146.52 simplex, and repeater VE3TBF on 147.24/.84. Special QSLs for working XJ3TBC on receipt of your log information. A certificate award is available for working XJ3TBC on any three different bands on receipt of your log in-

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

How did that Gershwin tune go? "Summertime, and the RTTY is easy"? Well, the season is upon us, and it's time to see what the mailperson brings.

Al Baketel K7ZMO of Kennewick, Washington, sends along his RTTY transmitting program, which he combined with the receiving program published in last year's RTTY Loop. Al has submitted it to the LFD-400 User's Group for owners of 6800 systems and Percom disks, and I am sure that users of compatible systems will appreciate his efforts.

Victor Johnson, in Minneapolis, Minnesota, writes requesting a similar RTTY program written for the H-8, the Heathkit 8080-based system. While there have been several RTTY programs published in the various ham magazines, I have yet to find one written specifically for the H-8. I do not know if the architecture of this machine would prevent using programs written for other 8080-based systems, but I invite any readers with information on such a program to drop me a line and let me know. Victor also asks one of the most common questions of newcomers to the Green Key set: "Where can I get equipment?" I would urge you all to check the ads in *73* carefully and make contact at your local ham club or clubs. Frequently you may be able to find a machine locally which would normally go unsold; let someone know you are in the market.

Another RTTY neophyte (or is it neo-RTTY-phyte?) is Jerry Strauss KB6BP (ex-WB6QIN), of Yorba Linda, California. Jerry followed a rather interesting course in his entry into RTTY. He notes that as an active ham for 15 years, he had always wanted to get into RTTY, but the thoughts of "all those gears, printers, etc." was totally foreign and somewhat frightening to him. So, when Radio Shack came out with the TRS-80 and a RTTY adapter was developed and marketed by Microtronics, he decided to kill the proverbial two birds and get into RTTY and have a computer, too. He states that the system worked well, but that there were problems. The most troublesome one he noted was the leakage of TRS-80 square waves into his receiver, particularly on twenty meters. So, Jerry followed the path most of us travelled in the other direction and bought a Model 28 and a HAL ST-5000. Now happy on RTTY, he is looking forward to the purchase of punched tape equipment soon. He also has thought about installing a spark gap, I suppose. Seriously, Jerry's letter raises an important point that needs to be emphasized more and more these days. You *don't* need all the super-modern gizmos with video displays, memories, and ASCII to enjoy RTTY. Whether you are using the lowliest thirty-year-old printer covered two inches deep in grease and dust or a $10,000 computer system with triple buffers and direct memory speed inversion, once that signal goes out on the air, it is the same 60-wpm Baudot code. We can all talk to one another. That's what makes it so much fun!

Jim Dollinger WB9QPY echoes that sentiment in another letter. While Jim is using all the "standards," Model 19, etc., he is also interested in video terminals and such. He would like to see more about UARTs, and we hope to have more about these interesting devices in the future. Jim also asks for tips to convert a TV set to a video display. The "source authority" (as they used to say on *Jeopardy*) for that information would probably be Don Lancaster's book, the *TVT Cookbook*, available most anywhere from Sams and now "second-sourced" by Radio Shack. Another description can be found in the July, 1977, issue of *Kilobaud Microcomputing*, page 30. Grant Runyan writes of "The Great TV to CRT Monitor Conversion," and that may be just what you're looking for.

Whew! With all this talk of sophisticated RTTY equipment and state-of-the-art techniques, we sometimes lose sight of the simple puzzles that confront the neo-RTTY-phyte (I like that word!). R.E. Ferguson, from Wolf Point, Montana, writes: "I have a Model 15 TTY. The line feed double spaces. Can this be changed to single line spacing?"

Well, R.E., the Model 15 was set up to provide either single or double line feeds. The double setting is commonly used in commercial press, where double-spaced copy is easier to read on the air or to edit for publication. I will admit that it has a tendency to waste paper when used on the ham bands and is less than desirable when someone is sending you a picture.

Fig. 1 is a diagram of the left side of the Model 15 platen as you face the machine. The Model 19 is the same, of course. The winged lever protruding out of the side is called, would you believe, the single-double line-feed lever. When the lever is up, the machine will line feed once upon receipt of a "line feed." When the lever is down, two line feeds are issued. I suspect your machine is set in the "down" double-line-feed position.

In case you have to adjust this mechanism, you may wish to operate the motor by hand, with "line feed" coded in to assess the way the pawl latches a toothed wheel to produce the line-feed action. This pawl is called the detent lever, and where it hinges is termed the "detent-lever eccentric screw." This screw, when rotated, changes where the pawl hits the ratchet that turns the platen. If, after checking the position of the "single-double line-feed lever," the machine is still double line feeding, you may need to turn the eccentric. Note, if you do, that there are two positions of the detent-lever eccentric screw which will provide correct adjustment. You should use the position which applies the least tension to the detent-lever spring and be sure that the detent roller rests in the bottom of a notch on the detent ratchet. To sum up, as with all adjustments to TTY machines: Good luck, don't force anything, and if you are not sure what you are doing, ask for help.

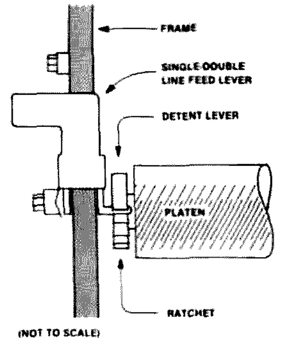

Fig. 1. Single-double line feed on the Model 15/19.

Quite a few responses have been received to the question about commercial RTTY frequencies. In general, a few points have come up. Commercial RTTY stations, if using Baudot code, are rarely following ham conventions. That means they frequently use strange shifts, like 425 Hz, speeds, like 67 wpm, and transmit "upside down," with high shift. Nonetheless, they are copyable if you know where to look and have equipment which can copy.

The shift problem can usually be obviated by "straddle tuning," with autostart and the like turned off. Most all converters can invert an upside-down signal. The speed problem is a little tackier, but a Model 15 will copy 67 wpm with adjustment of the range control, usually. Those of you with Model 28 systems or computers should have no problems.

As far as where to look, there is really all kinds of advice. The September, 1977, issue of *73* carried an article on page 52, "RTTY SWLing," by Webb Linzmayer, which presented several long lists of signals copied that year in New Jersey. Bob Melville K3WRV passes along the guidance to look around three and seven MHz, where he finds quite a few interesting signals.

Bill Mauldin, of Boca Raton, Florida, passes along the information that the Voice of America operates on 14638 kHz, 100 wpm, with full-time news, in English and Spanish. Weather information is all over the place; one might try 10950 kHz, 16440 kHz, 8110 kHz, 8130 kHz, and 18765 kHz. All of these are also 100 wpm, 850-Hz shift. The weather transmissions use the "weather" code, which uses different symbols to represent cloud cover, etc. We will cover interpretation of some of these codes in a future column.

So scout around and let me know what you find. If I hear it, too, so much the better! I will try to pass along any good information to you all, the links in the RTTY Loop.

Ham Help

I am in need of a manual or schematic for a Hallicrafters general coverage receiver, model S-38D. I will be happy to pay any postage or duplicating costs.

William P. Smith K3LF
RD#2,
Cold Spring Creamery Rd.
Doylestown PA 18901

Can anyone help me find a manual and schematic for an Allied AX-190 receiver? I would appreciate any help.

Mike Marmer KB8GH
2749 Symphony Way
Dayton OH 45449

I would like to get in touch with hams who are former members of the Civilian Conservation Corp (C.C.C.).

Joseph Schwartz K2VGV

New Products

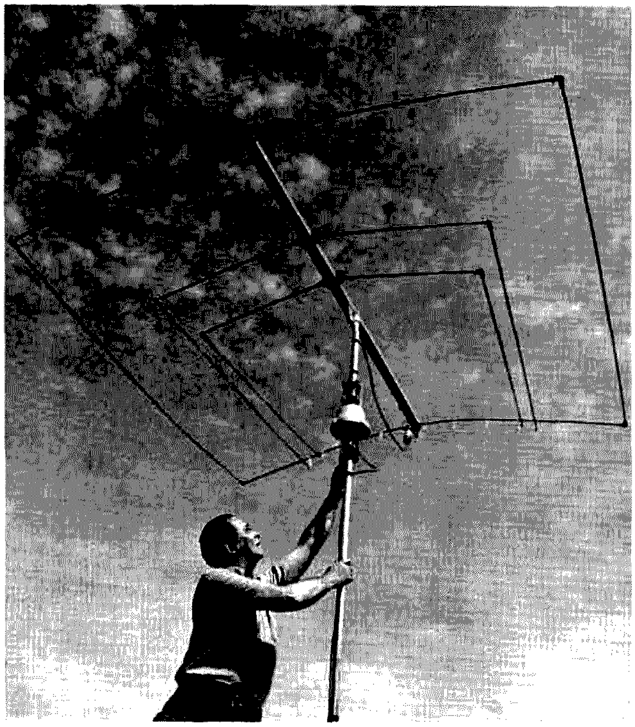
TEMPO INTRODUCES NEW K6FZ MINIATURE TRIBANDER ANTENNA

Henry Radio has announced the full availability of a new miniature K6FZ 20/15/10 meter tribander antenna under its Tempo brand name. Measuring only 8 feet square, the new antenna is based upon a full half-wave-long constant-current loop design using capacitive phase shifters in the outer arms to achieve front-to-back ratios on the order of 15 dB. Gain over a full-size dipole is 1 dB.

The new Tempo tribander is constructed mainly of exceptionally strong and lightweight fiberglass antenna rods made by Monogram Industries. A copper conductor is positioned centrally in each rod. The basic antenna is the 20 meter loop (onto which the smaller 15 and 10 meter loops can be mounted optionally). Elements screw or snap together in a matter of minutes to simplify assembly or disassembly, a feature of particular interest to field day and DXpedition enthusiasts. The overall weight of the tribander is 14 pounds, and the antenna can be rotated, if desired, by any inexpensive TV rotor.

In addition to its more than adequate front-to-back ratio and gain, considering its small size, the bandwidth on 20, 15, and 10 is exceptionally wide. The 20 meter resonant frequency is set by rotating a knob in the boom to any desired spot. On 10 and 15 meters, the user can select operation on either phone or CW. The power rating is a full kilowatt. One common 50-Ohm feed is used for all three loops, and swr is adjustable to 1:1 on 20. It is almost as low on the other two bands.

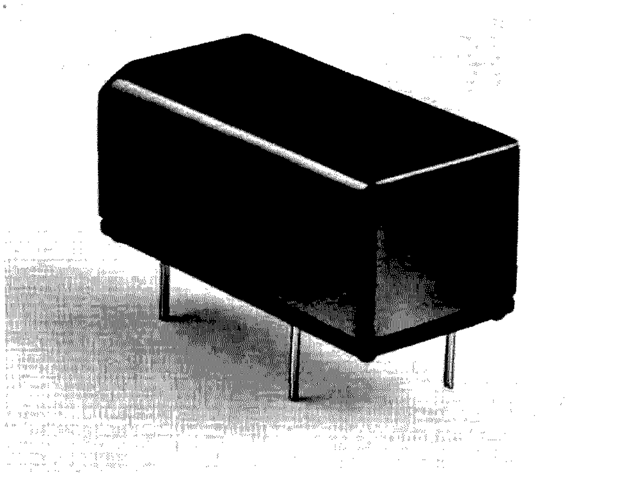
Looking like a TV antenna to laymen and angry neighbors, the new Tempo tribander can be the answer to the amateur "shut-in." Where rooftop mounting is not possible, the antenna can be hung in an attic, in a tree, or just about anyplace and still put out a creditable signal. For further information, contact *Henry Radio, 11240 W. Olympic Blvd., Los Angeles CA 90064; (213)-477-6701.* Reader Service number H3.



New Tempo miniature tribander.

DIP NICKEL CADMIUM BATTERIES ANNOUNCED BY PANASONIC

Two models of DIP (dual-in-line) nickel cadmium batteries for easy mounting on printed circuit boards are now available from the Electronic Components Division of Panasonic Company. Designated as "MEMORY MOUNT™" nickel cadmium, the new batteries are available in two voltage ratings —2.4 and 3.6 V dc—with the capacities of 110 mAh. The rectangular DIP package offers pins that have standard PC-board spacing.

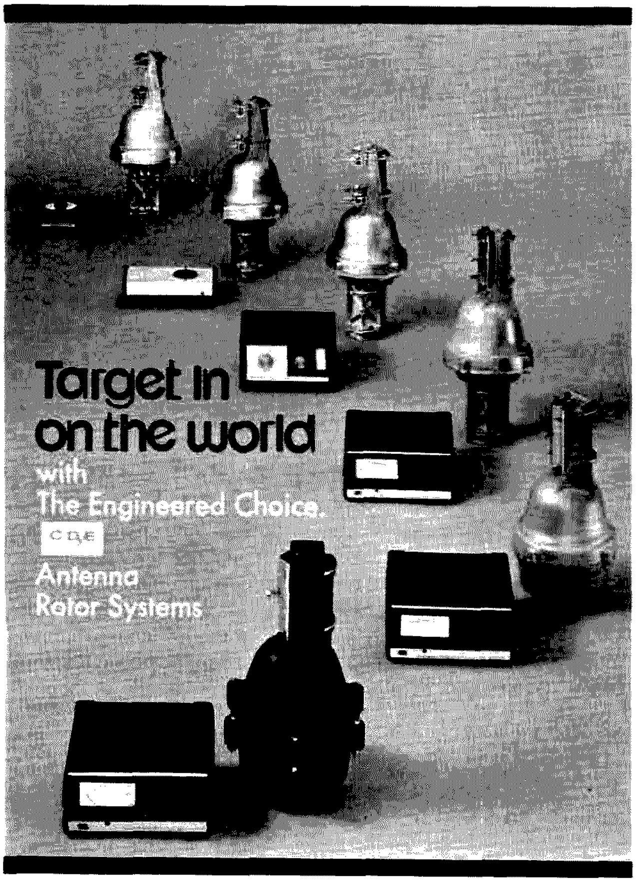


Panasonic's new DIP nickel cadmium battery.

To prevent accidental battery discharge during the widely-used wave soldering of PC boards, the new DIP batteries are available in the discharged state. Once they have been soldered into the PC board, they can be charged to the desired capacity.

The new DIP batteries offer standard high-performance characteristics of Panasonic nickel cadmium rechargeable batteries. These include good capacity retention, 500 or more charge-discharge cycle capability, and high degree of cell uniformity.

These new batteries will be available after July. For further information, contact *Panasonic Company, Electronic Components Division, One Panasonic*



CDE's new antenna rotor brochure.

Way, Secaucus NJ 07094; (201)-348-7136. Reader Service number P31.

NEW BROCHURE DESCRIBES COMPLETE LINE OF CDE ANTENNA ROTOR SYSTEMS

Cornell-Dubilier Electric Corporation has released a new eight-page color brochure presenting their complete line of antenna rotor systems. Each of the six rotor systems is illustrated and described.

They include: the Tailtwister™, designed for king-sized antenna arrays of up to a 30 sq. ft. wind load area; the new Ham IV™, the latest version of the world-famous Ham series; the new CD 45, incorporating professional features at a popular price; the BIG TALK™, with IC control that lets you preprogram locations most commonly used; the AR 40, a deluxe unit with solid-state accuracy and silent operation; and the AR22XL, a popular system with automatic control. Included in the CDE Antenna Rotor Systems brochure is a breakaway photograph of the time-tested Bell rotor.

For further information, contact *Leonard Sabal, Cornell-Dubilier Electric Corporation, subsidiary of Federal Pacific Electric Company, 150 Avenue L, Newark NJ 07101; (201)-589-7500.* Reader Service number C143.

SENCORE INTRODUCES NEW IN-OR-OUT-OF-CIRCUIT POCKET CRICKET TRANSISTOR TESTER

Sencore has recently introduced a new pocket-sized transistor tester to meet the increasing need of solid-state field service. Battery-operated, and weighing only 14 oz., the Pocket Cricket is totally prepared to check virtually all transistors and FETs on the market, in or out of circuit. No setup book or transistor data is needed at all to check transistor gain and leakage between all transistor elements. This patented new device has the unique capability of automatically connecting the test leads for test, regardless of how they are connected to the transistor. For test lead identification, a 12-position switch is rotated through all positions until the Cricket "chirps." The chirping noise notifies the user that the leads are connected correctly and the switch control points to the test lead connections. Gain is simply read as good or bad on the meter scale for fast field operation.

The TF54 Pocket Cricket also identifies the component being tested as a transistor or FET during the test, should the user not be able to identify a replacement transistor. The company claims 99.9 percent testing reliability.

New features, not found on small transistor testers made by Sencore, include solid action bat handle switches, a D'Arsonval meter movement for more accurate leakage measurements on critical transistors, and an automatic off circuit that turns the instrument off after 10 minutes of use (to save batteries). The instrument can be ac-operated on the bench with an optional PA208 power adapter. Other accessories include a three-pronged touchtone probe (part no. 39G85) for easy connection to a printed circuit board and a highly durable leatherette carrying case (part no. CC217).

For further information, contact *Sencore, Inc., 3200 Sencore Drive, Sioux Falls SC 57107; (605)-339-0100.* Reader Service number S102.

Optoelectronics' new PDT-590 digital thermometer.

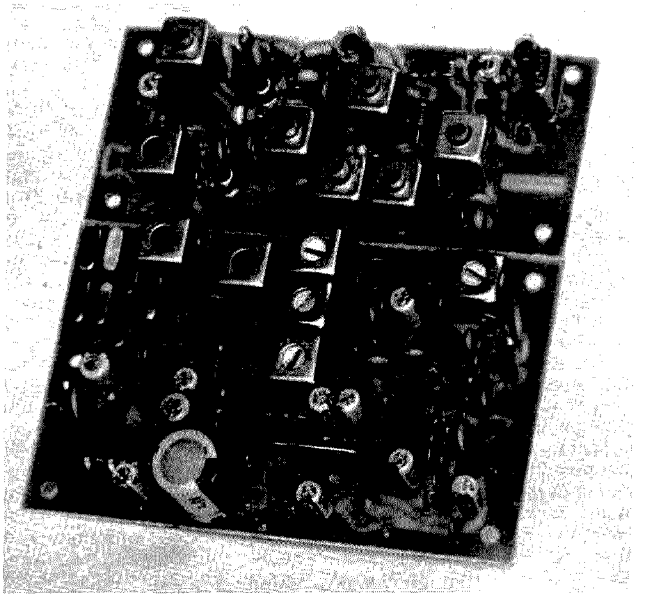
PRECISION DIGITAL THERMOMETER

Optoelectronics' new precision Celsius/Fahrenheit digital thermometer has .1° resolution and two sensors (switch-selectable). The PDT-590 has a −50° C to +150° C (−60 to +200° F) temperature range with better than ±.7° accuracy. Two laser-trimmed temperature-to-current transducers can be remoted over hundreds of feet of two-conductor cable without noise pickup. The switch-selectable Fahrenheit or Celsius temperature is displayed on four .43-inch high-intensity LEDs. The PDT-590 is enclosed in an attractive heavy-duty bronze aluminum case and is provided with a 115 V wall plug transformer for ac operation. Optional internal nicad batteries provide several hours of portable operation. Size: 1¾" H x 4¼" W x 5¼" D; weight: 14 ounces. For further information, contact *Optoelectronics, Inc., 5821 N.E. 14th Avenue, Ft. Lauderdale FL 33334; (305)-771-2050/1.* Reader Service number O3.

VHF FM RECEIVER KITS FROM HAMTRONICS

Hamtronics, Inc., has just announced an exciting new series of VHF FM receiver kits. The model R75 is the fourth generation receiver by Hamtronics, and it incorporates all the design features of the previous designs—plus some new ones. The chief feature of the R75 series is a wide range of selectivity options. Four models, with different crystal filters, provide the optimum selectivity for each type of service, ranging from

Sencore's Pocket Cricket.



A Hamtronics VHF FM receiver board.

±30 kHz at −60 dB for weather satellite reception to ±15 kHz at −100 dB for demanding split-channel repeater service. Other features include increased sensitivity, smaller size, and easy construction. The 4- x 4¼-inch receiver consists of two PC boards, allowing for mounting flexibility. Kits are available for the 10m, 6m, 2m, and 220-MHz ham bands. They can also be used on adjacent commercial and weather satellite frequencies.

For more information, contact *Hamtronics, Inc., 65F Moul Rd., Hilton NY 14468; (716)-392-9430.* Reader Service number H16.

MFJ's Signal Enhancer II.

A LOOK AT THE SIGNAL ENHANCER II

In the fifties and sixties, the best way to improve receiver selectivity at low cost was to add one of the outboard devices popular then, such as a Q-multiplier (which worked on the set's i-f stages) or a war surplus radio range filter (which was inserted in the set's headphone lead). Both methods left a lot to be desired.

It seems that suddenly hams have discovered that the easiest—and in some ways, most cost-effective—way of improving receiver selectivity is to add an outboard audio filter. The popularity of these so-called "active" filters has not been lost on manufacturers either—perhaps a dozen make these handy accessories, including Kantronics, Datong, Electronic Research Corporation of Virginia, Dynamic Electronics, Palomar Engineers, Waneco Radio, Autek Research, and MFJ Enterprises.

MFJ has come up with several good designs, each one better than the one preceding it, with each mod adding new convenience features. Their latest "maxi-filter" is the Signal Enhancer II, a very attractive dual tunable design intended to remove interference from SSB, AM, CW, and RTTY signals. The ads for the new filter stressed its flexibility and improvements over earlier models, so I arranged with the hams at MFJ to put one of the new filters to work in my ham shack.

The Model 752 filter arrived on a Friday afternoon, and by that evening I had digested the installation instructions. From the instructions, I learned that the 10" x 2" x 6" cream-and-walnut cabinet contains not one, but *two*, independent filters. The main filter is a two-section, four-pole variable filter with four major functions: peak, notch, lowpass, and highpass modes. There is also a second "auxiliary" filter having peak and notch functions only. (The idea of having two filters is to allow you to peak or "enhance" the desired signal while at the same time you remove or "notch out" QRM.) The four-page instruction manual and the catalogue that was included in the shipping package told the facts: The main and auxiliary filters allow selectivity down to 40 Hz bandwidth, variable over the frequency range of 300 to 3000 Hz, and the notch depth goes all the way down to 70 dB. Six front-panel controls allow function selection (bypass, on, and SSB or CW noise limiter), main filter operating mode (peak, notch, lowpass, or highpass), and main filter selectivity and frequency adjustment. There are also two controls for the auxiliary filter, which can be operated simultaneously with the main one. The auxiliary selectivity control has a push-in, push-out feature so that either the peak or notch function can be selected with a gentle push on the control knob.

The filter came complete with a 110-volt power supply; it's of the "external power adapter" types commonly used with portable radios and small tape recorders. The filter will also run directly from any 9-18-volt source of filtered dc. The audio from the rig is connected to the filter input by means of RCA-type phono plugs; the MFJ-752 can accommodate two inputs which are selected by a rear-panel slide switch, allowing you to connect two rigs to the filter. A standard (¼") phone jack is used to hook up your regular station speaker; the speaker line is disabled whenever headphones are inserted into the headphone jack on the rear panel. I should point out that this jack is of the *2-circuit* (stereo) type; it's best used with stereo headphones to take advantage of the so-called "simulated stereo" feature. (When you use stereo phones, unfiltered audio directly from the receiver is fed to one earphone; the other ear gets "processed" or filtered audio. Mono headphones can be used if the stereo feature isn't wanted. More on this later.)

The power switch is the main control. When power is off, the filter is cut out of the circuit and audio is routed directly to the speaker or headphones. In the "on" position, the filter is in business, without the noise limiter feature. Going to NL/SSB or NL/CW, noise limiters are cut in that are designed to limit impulse noise peaks and remove background noise.

Having owned the Autek QF-1 and QF-1A filters, both excellent units, I found tuning and adjustment a bit more complicated using the Signal Enhancer II—possibly because there are more knobs to turn! Once I got the hang of it, though, I found that it did a good job on both CW and SSB in slicing through QRM and QRN. On CW, I could zero-in on the desired signal in the peak mode and almost completely eliminate other signals by carefully adjusting the selectivity and frequency controls. I found that the lowpass mode was "super" for CW work; signals could be boosted even more so than in the peak mode, and this mode gave more audio output to boot. (Because circuit gain rises in the lowpass mode, you have to watch the input audio level to prevent overdriving the filter with consequent distortion.)

I also prefer using the lowpass mode on SSB, although peak and notch can also be used depending on QRM conditions. If heterodyne QRM is the major problem, you can run in the notch mode, adjusting the frequency control to null out the offending signal. You can run in any main filter mode and cut in the auxiliary filter in either the notch or peak modes. For instance, you can, when working SSB, operate the main filter in the peak mode, adjusting the frequency and bandwidth controls for best audio response, and then—using the auxiliary filter—notch out any annoying heterodyne. On CW, you can kick in both the primary and auxiliary filters to yield very "tight" selectivity with little ringing, or you can peak with the main filter and notch out another signal with the auxiliary filter. The possibilities are almost endless and are really limited only by your imagination and dexterity!

I found the noise limiter circuits very useful, even though my transceiver (a Tempo 2020) has a built-in noise blanker. The limiters were especially helpful when used in conjunction with my Yaesu FRG-7, whose ANL (automatic noise limiter) works only on AM signals. The limiters did, however, cut down on the filter's audio output (particularly noticeable when using a speaker rather than headphones), and the CW limiter had to be used judiciously (as it could be overloaded and start to "chop" the desired signals if the receiver's audio gain were run too high). The trick is to set the audio or rf gain on your rig at the right level so that the signal is passed but the noise is blocked.

A tinkerer, I also tried the MFJ filter with my KLM-2700 multimode 2-meter transceiver and with a JC Penney 6237 AM CB base station set. The filter worked surprisingly well with the KLM rig, especially on SSB and CW where there is no provision to install optional, sharper i-f filters. On FM, there was no noticeable selectivity improvement, although the filter's controls could be adjusted to modify and enhance the set's audio response. When using the MFJ unit with the Penney CB transceiver, a very noticeable improvement in selectivity was obtained, and it was easy to null out AM carrier heterodynes. The noise filter was effective with both units (even on FM), despite the fact that the KLM rig has a built-in noise blanker and the Penney CB set is equipped with an adjustable noise limiter.

The "simulated stereo" feature took some getting used to, but has its place, particularly on CW. The idea is to have "raw" receiver audio fed to one ear and filtered or "processed" audio fed to the other. This unique feature allows you to copy off-frequency stations in one ear while you simultaneously hear "single-signal" audio in the other; the brain hears all the signals, but the processed signal stands out from the pack. I found that working in the simulated stereo mode cuts down fatigue as well. The kind of phones with individual volume controls on each ear work best, since you can easily strike a balance between processed and unprocessed audio levels.

A couple of cautions are in

Microcomputer Interfacing

David G. Larsen
Peter R. Rony
Jonathan A. Titus
Christopher A. Titus

In many analog-to-digital converter applications, it is too expensive to dedicate one A/D converter to each sensor. An alternate approach is to share one A/D converter among several sensors. This is called *multiplexing*, since many signal sources share a common transmission path to a single receiving device, in this case, the A/D converter.

A multiplexer may be a rotary switch having multiple taps or positions (Fig. 1), a small-signal reed relay available in a dual in-line package (DIP) the size of a 14-pin or 16-pin integrated-circuit device, a semiconductor switching device based upon *complementary-metal-oxide semiconductor (CMOS) or metal-oxide field-effect transistor* (MOSFET) technology, or a complex communication device used by the telephone companies. Some of the advantages of semiconductor switches that make them practical for multiplexers are: 1) small size, i.e., housed in a standard dual in-line package; 2) directly compatible with TTL signals; 3) built-in on-board digital decoders for channel select; 4) positive and negative signal inputs, i.e., bipolar operation; 5) high speed switching; 6) long life, i.e., no mechanical wear; 7) low contact resistance, less than 100 Ω; and 8) high off-state resistance, 100^9 Ω typical.

Semiconductor switches are not ideal devices, and they too have some limitations or constraints that must be considered prior to their use in multiplexer circuits. Almost all such switches require two power supplies, typically +15 V and −15 V. Signal inputs cannot exceed these potentials without damaging the device. Most of the semiconductor switching devices, particularly the CMOS and MOSFET devices, are easily damaged by static electrical discharges, such as those produced by synthetic fabrics, rugs, etc. Newer designs incorporate static protection devices within the multiplexing integrated circuit device. Early semiconductor switches were susceptible to a problem called *latchup*, which caused them to act as though they were silicon-controlled rectifiers. Once they were turned on to pass a signal, they refused to turn off until the input signal reached zero volts.

A variety of signal sources can provide outputs to be multiplexed. These outputs can include low-level thermocouple signals, high-level pressure transducer outputs, dc and ac outputs, and high and low frequency outputs. These types of signals may all be multiplexed successfully, although some premultiplexer and post-multiplexer signal conditioning may be required. As an example, low-level signals may require amplification before they are input to a multiplexer, since transient signals may be large enough to cause significant errors in the low-level multiplexer output. If necessary, the resulting amplified and multiplexed signal may be attenuated after being multiplexed. Alternatively, a post-multiplexer filter could be used to remove un-

Continued on page 136

GLOSSARY

Bandwidth	The ability of the multiplexer to pass a signal at a particular frequency once it is turned on. The bandwidth is the −3 dB point and is equivalent to the *small-signal bandwidth* associated with sample-and-hold devices.
Crosstalk	A measure of the amount of a signal input to an "off" channel that appears at the output of the multiplexer superimposed upon the signal passed through the "on" channel. This is a direct function of the frequency of the signals, since the semiconductor switches are capacitively coupled within the integrated circuit chip. The higher the frequency, the greater the crosstalk. This phenomenon is similar to the *feedthrough* problem associated with sample-and-hold devices.
Settling time	The time necessary for the multiplexer's output to be within a certain error percentage of the input signal once the channel is *selected*, or turned "on." This time may be specified either as the switching time of the semiconductor switch plus the analog output settling time, or as the analog output settling time alone.
Switching transients	Transient voltage spikes that appear at a multiplexer's output when the multiplexer is switched from one channel to another and one of the switches is turned off. Such spikes may cause inaccurate measurements if the output is sampled, digitized, or integrated during this time.
Throughput rate	A measure of the fastest channel-to-channel switch rate that may be used if the rated accuracy, generally 0.01%, is to be achieved.

Awards

Bill Gosney WB7BFK
4471 40th N.E.
Whidbey Island
Oak Harbor WA 98277

Welcome to *73*'s new "Awards" column. To offer some variety, both domestic and DX-type achievements will be outlined here. Naturally, I must ask our readers to submit additional award news and information as it becomes available. I would like to encourage you to check with your local radio club to see if they might have an award they sponsor which would be of interest to our readers. Ask them to submit a copy of their award program rules along with a sample copy of the award certificate.

Just the other day I received a cheerful note from Tom Owens K7RI, president of the Western Washington DX Club. Tom, along with awards chairman Morris Shepard W7LVI, provided me with the latest up-to-date information about the Washington Totem Award, sponsored by their DX organization.

The Washington Totem Award was initiated in 1973 by the Western Washington DX Club, thus becoming the first major W7 award available to the amateur community. It used as its motif the colorful totem pole, symbolic of the Indian culture of the Pacific Northwest.

The first award was issued to 9X5NA; to date, 133 awards have been issued to 61 DX countries. To qualify:

1. Applicants must submit proof of QSOs with 100 different Washington stations. Twenty (20) of these must be confirmed contacts with different Western Washington DX Club members. DX stations need only confirm twenty-five (25) Washington stations including ten (10) WWDXC members.
2. General certification rules apply. Submission of QSL cards is not required. Cards may be checked and certified by an officer of any recognized club or society. DX stations may submit log data in lieu of QSL card confirmation.
3. To be valid, all contacts must have been made January 1, 1973 or later.
4. Certified lists submitted must be in alphabetical order, with date and time in GMT.
5. The Washington Totem Award is free to all stations outside of the United States. US stations must include an application fee of $1.00. If QSL cards are sent to WWDXC for checking, sufficient postage for their safe return must be included with the application and confirmation list.
6. Special endorsements will be issued for specific band or mode accomplishments if all supporting information is included with the application.
7. The WWDXC will furnish a current membership listing upon request (and SASE). Mail all inquiries to: Awards Manager, WWDXC, Inc., PO Box 224, Mercer Island WA 98040, USA.

I might hint to our readers wishing to seek this award that members of the Western Washington DX Club sponsor three DX Nets daily. To be part of the "W7PHO Family Hour," tune to 14.225 MHz at 1400 and 2300 GMT and to 21.320 MHz at 0000 GMT daily.

While on the subject of domestic awards, particularly those from Washington State, I cannot go without mentioning the awards program sponsored by the Boeing Employees' Amateur Radio Society, more commonly referred to as the BEARS. The BEARS offer quite an array of incentives for parchment pursuers. Let's take a closer look at each one individually:

WORKED FIVE BEARS AWARD

This award is offered for those stations confirming contact with at least five (5) members of the Boeing Employees' Amateur Radio Society. There are no band, mode, or time restrictions. General certification rules apply.

WORKED THREE BEAR CUBS AWARD

Issued specifically to any station confirming contact with at least three (3) Novice members of the Boeing Employees' Amateur Radio Society. There are no

You Can Watch Those Secret TV Channels

—a complete MDS receiving system

Good-bye, commercials!

Jim Barber K0JB
Rt. 1, 22518-97th Ave. North
Rogers MN 55374

Jevon Lieberg K0FQA
Rt. 1, 12285 Genereux Place
Rogers MN 55374

Did you know that there are two secret TV channels? Nobody advertises them, and you can't even buy a TV set that has these channels.

How long have you been complaining about all the commercials while watching your favorite program or a late night movie? Well, here is the answer to your prayers—*these channels don't even have commercials!*

The programming on these channels consists of movies (P-, PG-, and R-rated), nightclub acts, and sporting events. They are allocated to Multipoint Distribution Service (MDS). The existence of these channels was written up in *73* last November.[1]

If you have heard of MDS via other amateurs, friends, or magazine articles, your curiosity has probably urged you to be on the lookout for a receive system you could build yourself. If this is true, read on!

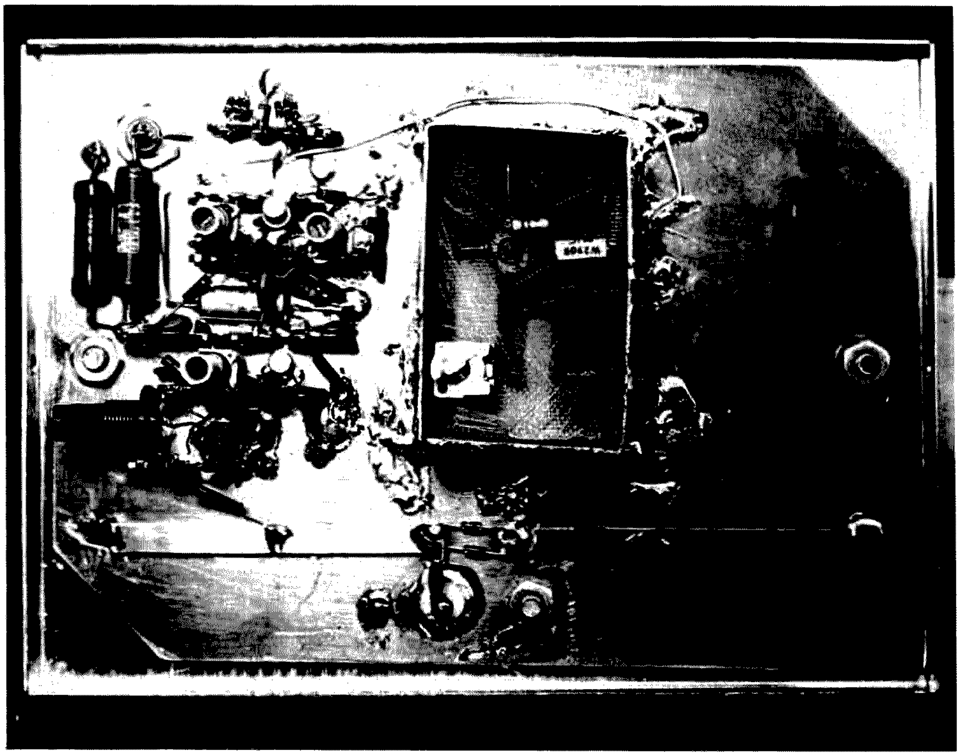

Photo A. This is a close-up of the downconverter showing i-f amplifier, mixer, and the local oscillator in its brass box with the cover removed. The piece of angle aluminum used to mount the box to the mast can also be seen.

The MDS Receive System

In this article we will give complete construction details on how to build a cheap and simple MDS receive system. This system will include the antenna, mixer, local oscillator, i-f amplifier, power supply, and complete mechanical layout.

The frequencies of the two microwave MDS video channels are 2154.75 MHz for channel 1 and 2160.75 MHz for channel 2. The audio is 4.5 MHz below the video. For more detailed information about microwave TV, read *A Vidiot's Guide to Microwave TV* by Paul Shuch.[2]

Locating the MDS Transmitter

If you have seen or

heard of small dish antennas located on apartment buildings or hotels, this indicates that there is an active MDS channel nearby.

There are several ways to locate the source of the MDS signal in your area. If your city has an FCC office, they will have a list of all allocated frequencies and the locations of the transmitters. This list is on microfiche and is public information. Stations are listed by their frequency, so look up both MDS channels. The location will be given by latitude and longitude; with a good map, you will be able to pinpoint it.

Another way is to note the direction of several receiving antennas on buildings and use triangulation to find the transmitter. If you can find out the name of the company offering MDS service locally, just call and ask them. One thing is certain—it will be located on one of the highest structures around. After all, their objective is to be line-of-sight to as large an area as possible.

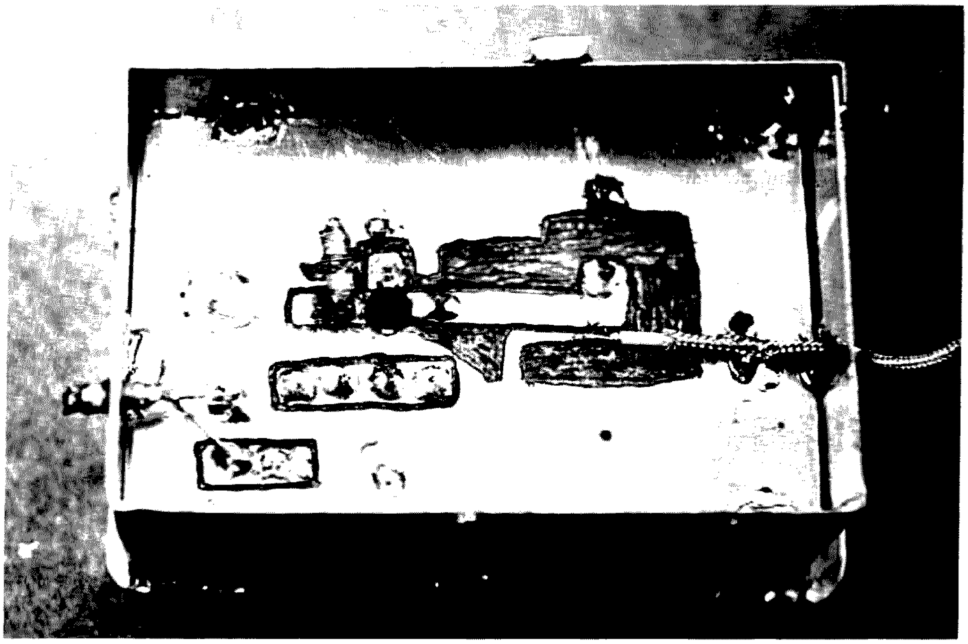

Photo B. This picture shows a close-up of the foil side of homemade printed circuit board used for the local oscillator. Note the modified feedthrough capacitor used for a base bypass capacitor. A 270-pF disc with very short leads also can be used.

Checking the Receive Path

After finding the source of the MDS signal, you must confirm your location as being suitable for good reception. As you know, microwave signals generally travel only in a straight line, and obstructions such as trees and buildings severely attenuate the signal strength. As a rule of thumb, if you can see the building or tower where the MDS transmitting antenna is located, no matter how distant, then you have a very good location.

If you are line-of-sight, you will not gain much by increasing the height of the antenna. In other words, don't put your antenna at the top of your fifty-foot tower if you can see the location of the signal source from your living-room window. Some obstructions can be tolerated if not too severe, and the signal loss can be made up through the use of preamplifiers and/or a larger antenna.

Circuit Description: Mixer

The mixer is the secret to a good microwave downconverter. It normally contains most of the critical parts and generally is the most difficult to construct. I think we can speak from experience on this subject, having built the interdigital converter by WA2CQH,[3] the high-performance balanced mixer for 2304 MHz by WA2ZZF,[4] and the solid-state 2304-MHz converter by K2JNG, WA2LTM, and WA2VTR.[5] Then, along came the October, 1978, *Ham Radio* magazine, with Jim Dietrich and his twin-diode mixer article.[6]

This mixer is so simple that you find it hard to feel that you have earned the quality of the signal that comes out of it. The mixer consists of two half-wave lines mounted above a ground plane. The first half wave is grounded on one end, and the other end has a pair of back-to-back diodes connecting it to the second half-wave line. This second line is open on its far end, and the i-f output is taken from the center of it.

The rf input is at the diode end of the second half-wave line, and the local oscillator input is at the diode end of the first half-wave line. (See Fig. 1 for detail.) The input circuit at the rf port is a high-pass filter to keep the i-f energy from getting out of the rf port. This filter also keeps the antenna input at dc ground. The output circuit at the i-f port is a low-pass filter to keep the LO out of the i-f. For a more detailed description of the mixer, read Jim Dietrich's article.[6]

The diodes used in the original article were MA4882. We were unable to get these locally, so we used Hewlett-Packard 5082-2835. This is a very

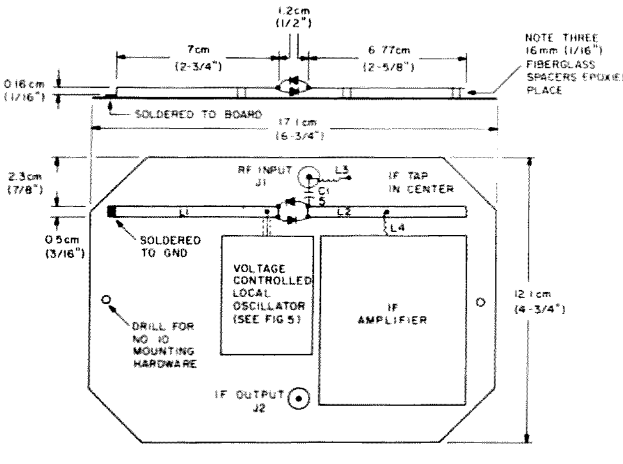

Fig. 1. General layout of the downconverter and construction details of the twin-diode mixer. J1 is a type N or BNC. J2 is an F61 TV-type connector.

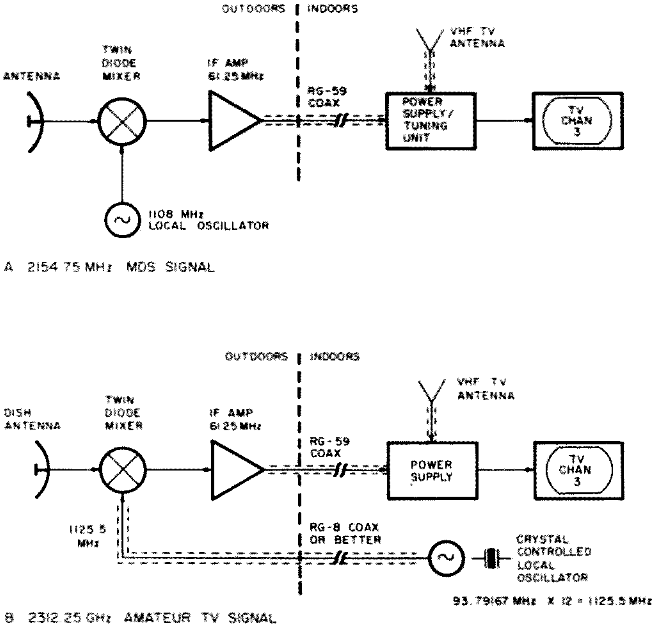

Fig. 2. (a) Block diagram of MDS receive system as described in this article. (b) Block diagram using alternate crystal-controlled local oscillator. Frequencies shown are correct to convert down to standard VHF TV channel 3 (video).

fine inexpensive diode for microwave mixers, but H-P does not give a noise figure rating for it. Any good Schottky diode can be in this circuit, but if you want to know its noise figure rating, you will have to pay more. The 2835 is about $1.10, and the prices go up from there. A good compromise, possibly, is H-P's 5082-2817. It has a 6-dB noise figure at 2 GHz and costs only $1.85.

Block Diagram

The block diagram shown in Fig. 2(a) is representative of the MDS receive system as described in this construction article. This system consists of a mixer, voltage-controlled local oscillator, and i-f amplifier located at the antenna, and the combination power supply/tuning unit, located at the TV set. The RG-59/U feedline then performs the dual purpose of carrying the i-f signal down the line to the TV and carrying the power supply/tuning voltage up the line to the converter.

This results in a nice, cheap, and efficient system requiring no expensive feedline and connectors and a minimum of critical circuits. No special test gear is required for tune-up.

The block diagram shown in Fig. 2(b) is one of many configuration alternatives possible and is shown mainly to provoke some thought about other uses for the basic system. An example of another use would be for fast-scan amateur television where the usual DX signal would be much weaker than an MDS signal, and the guesswork of tuning is eliminated through the use of a crystal-controlled local oscillator.

Circuit Description: The Local Oscillator

Building a satisfactory local oscillator is the next hurdle one must overcome in the construction of a microwave converter. You will be thankful to know that the twin-diode mixer helps us here, too, because this mixer requires an LO running at only half the frequency needed for other mixers.

In this system we have done away with all the drudgery of those crystal-controlled oscillator/multiplier chains also and settled on a nice simple free-running oscillator.[8,9] This oscillator has a tuning range of about 900-1300 MHz and a power output capability of several milliwatts. You might ask, "Is that possible? Won't it drift?" The answer to both questions is "yes." Not only is it possible, but it's also very simple.

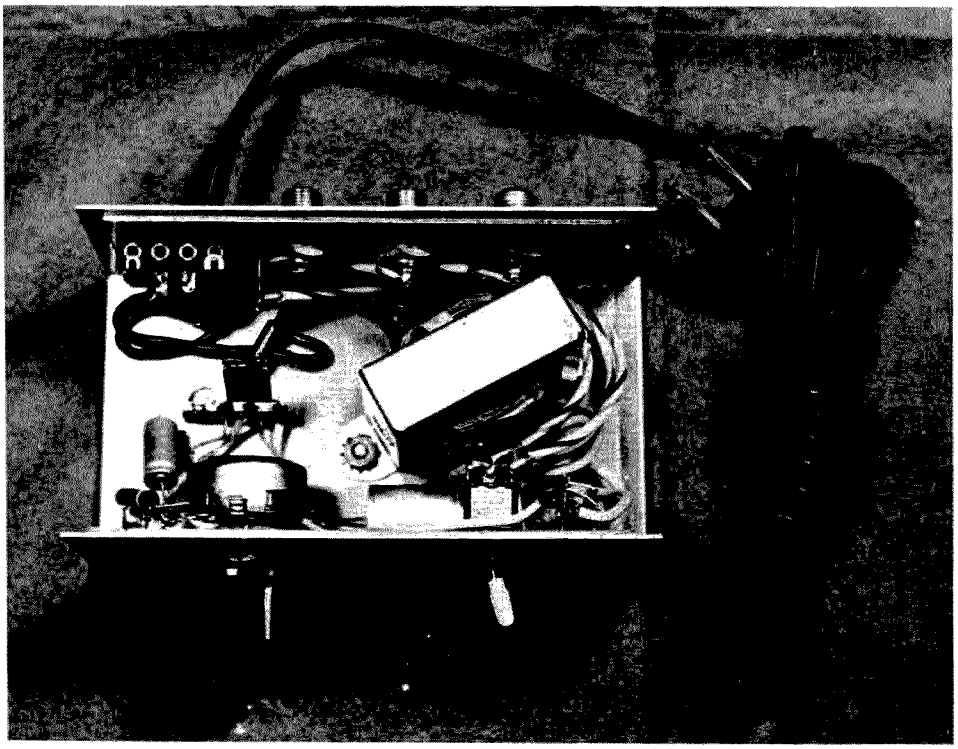

Photo C. This is a top view of the power supply/tuning unit.

The oscillator consists of a printed circuit board with an etched inductor, a Motorola MRF901 transistor, and about six other parts. This is about as simple as it could be. As far as drift goes, we have found that it is at a very slow rate, completely due to changes in outside temperature.

A TV set is a very broad receiver and will tolerate considerable dirft. Since this LO is a voltage-controlled oscillator and can be remotely tuned from the control box, frequency adjustments can be made at any time. If this type of stability is not satisfactory for you, you may wish to build a crystal-controlled LO. We might suggest the one used on the interdigital converter[3] with a doubler from a Paul Shuch article.[10] Possibly another consideration along this line would be the Paul Wade article in *Ham Radio*, October, 1978.[11] Although these alternatives would double the size of the converter, it may be worth it—particularly if you plan to distribute the signal to a number of TV sets. This is because, when tuning the converter for one TV set, the others are affected. This may be necessary once your neighbor finds out what you are watching.

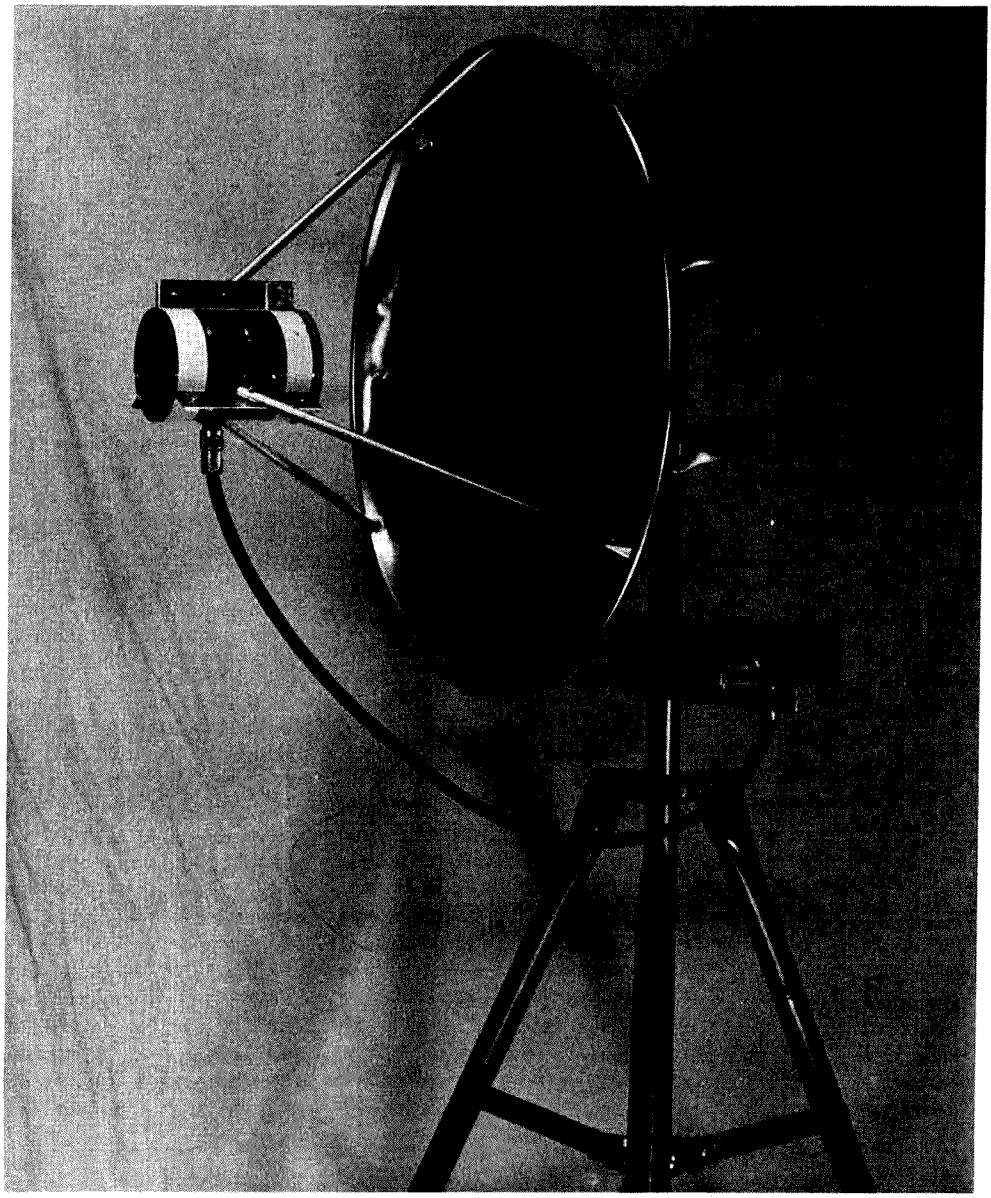

Photo D. This photo shows a complete MDS receive system. The tripod, mast, and U-clamps are standard TV items. All connectors and the box containing the downconverter should be weatherproofed.

Circuit Description: I-f Amplifier

The i-f amplifier is a two-stage amplifier using dual-gate MOSFETs. The function of the i-f amplifier is to boost the signal from the mixer and also provide enough power to drive the RG-59/U coax line to the control box and TV set. This amplifier has been used to drive up to 600 feet of RG-59/U cable with enough signal at the far end to still have a good picture. Although the center frequency is 63 MHz (channel 3), the amplifier is broad enough to cover channels 2 through 4. The output of the amplifier goes into a 75-Ohm, 3-dB pad. This pad gives the amplifier a constant impedance to look into, and, along with the ferrite beads on gate two of both of the MOSFETs, helps make this amplifier very stable.

Circuit Description: Power Supply/Tuning Unit

The power supply used in the MDS receive system performs two separate functions. First, it supplies the operating voltage for the i-f amplifier and local oscillator, and second, because it is adjustable and the local oscillator is frequency-sensitive to voltage, it provides tuning control for the downconverter.

The 24-volt ac transformer, diode bridge, and filter capacitor provide about 34 volts dc to the 12-volt regulator. The regulator is made adjustable by the addition of the fixed resistor, R1, and the variable resistor, R2. With the values shown in Fig. 4, the voltage is adjustable from 12 to 17 volts.

Rf choke RFC1 isolates the rf from the supply, and the dc is carried via the feedline to the downconverter. DPDT switch S1 performs the dual function of switching the TV between the VHF antenna and the MDS downconverter and properly terminating the unused lead with a 75Ω resistor.

It may seem that the current capacity of the power supply far exceeds the requirements of the downconverter, and it does. The

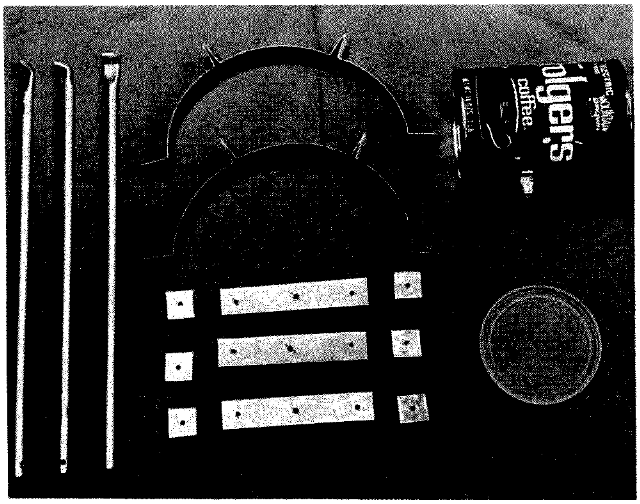

Photo E. This photograph shows the feedhorn before it was painted. Also shown are the supporting legs, straps, ties, and square washers used to mount the feedhorn in front of the reflector. The plastic cover that comes with the coffee can is used as a radome.

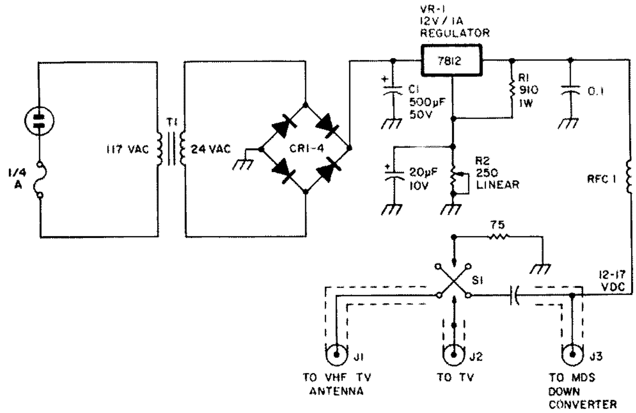

Fig. 4. Schematic diagram of the MDS downconverter power supply/tuning unit. T1 is 300 mA to 1 Amp at 24 V ac maximum. CR1-4 are 50 piv, 1 Amp, such as 1N4001. C1 is 500 uF or more. RFC1 is about 7 uH, such as Ohmite Z50 or Miller RFC-50. The three chassis-mount coaxial connectors, J1-3, are TV-type F61. S1 is a subminiature DPDT wired so that the unused cable input is terminated with a 75-Ohm resistor. A power switch seemed unnecessary, but don't forget the fuse.

overkill is for two reasons. First, there is generally no difference in the cost of the larger parts, so you may as well use them and have the added capacity. Second, the relatively stiff supply provides a very well-regulated voltage to the downconverter regardless of any power line changes.

Circuit Description: Antenna

The antenna is constructed from a child's 25-inch snow saucer and a one-pound coffee can.

The saucer is not a true parabola, but it is close enough to give 15+ dB of gain at 2 GHz.[12] It was chosen for its light aluminum construction and availability. The saucer used is manufactured by Mirro Aluminum Co., Manitowoc WI 54220; the model number is T3589. Another source is Sears. They have what looks like the same saucer in their toy catalog, and the catalog number is 79N85063L.

The one-pound coffee can is also readily available and makes an excellent feedhorn. This horn was described in the May, 1976, *Ham Radio* by WA9HUV.[13] This antenna has been compared with a commercial two-foot dish with a dipole and splash-plate-type feed. It was considerably better, but no attempt was made to measure how much better. When the same feedhorn was put on the commercial dish, it became the better antenna. So, if you already have a dish antenna and don't plan to use the saucer, we still recommend using this feedhorn. To find the focal length of surplus microwave antennas, see *Ham Radio*, March, 1974,[7] or the *RSGB VHF-UHF Manual*.[14]

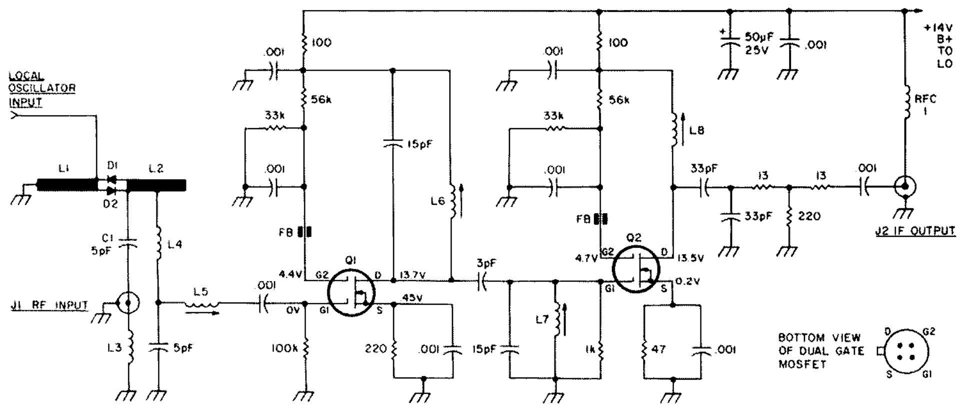

Fig. 3. Schematic diagram of i-f amplifier and mixer sections of the MDS downconverter. D1 and D2 are H-P 5082-2835, or the best microwave mixer diodes you can afford. Q1 and Q2 are Toshiba 3SK35 dual-gate MOSFETs; others, such as RCA 40673, work well. RFC1 is Ohmite Z50 or Miller RFC-50 (see power supply RFC1). L1 and L2 are shown in detail in Fig. 1. L3: 4 turns #28 AWG .3-cm (1/8-inch) diameter. L4: 15 turns #32 AWG .16-cm (1/16-inch) diameter (.085 uH). L5: 11 turns #22 AWG .56-cm (7/32-inch) diameter slug-tuned plastic form (.8-1.8 uH). L6-L8: 7 turns #22 AWG .56-cm (7/32-inch) diameter slug-tuned plastic form (.2-.6 uH). J1 is a type N or BNC chassis connector. J2 is a TV-type F61 chassis connector. Voltages shown were measured with a 10-megohm input VTVM.

Downconverter Construction

The downconverter is housed in an LMB 572, 12.7-cm (5-inch) by 17.7-cm (7-inch) by 5.1 cm (2-inch) aluminum box. The first step in construction is to cut a piece of .16-cm (1/16-inch) double-clad printed circuit board to the dimensions shown in Fig. 1. Cut off the corners and drill the holes to accommodate the coaxial connectors and mounting hardware. Also, drill corresponding holes in the cover of the LMB box at this time. Temporarily mount the board in the cover and, placing the cover on the box, check for clearance between the box and the

board.

Remove the board from the cover and begin building the twin-diode mixer. Cut the two copper or brass lines as shown in Fig. 1 and attach to the board by soldering the end shown as grounded, and using epoxy cement and three small .16-cm (1/16-inch) fiberglass spacers as shown. Scraps of PC board are used for the spacers. You may have to rough up the copper a bit with emery paper in order to get the epoxy to stick well.

Next, wire the i-f amplifier and complete the wiring of the mixer as shown in the schematic in Fig. 3. Use short, direct wiring, using the copperclad board for all ground connections. The unit shown in Photo A uses point-to-point wiring, using Bakelite™ terminal strips. This seems to work well, and no trouble has been encountered. Don't forget the ferrite beads on gate 2 of the two MOSFETs, and keep L5-8 as far apart from each other as possible.

The local oscillator shown in Photo B is built on a homemade printed circuit board. The board is a 4-cm (1½-inch) by 6-cm (2¼-inch) piece of .16-cm (1/16-inch) G10 single-sided circuit board. A Dremel Moto-tool® with a small carbide tipped burr was used to grind away the unwanted copper plating. Fig. 5(a) shows the circuit board layout and dimensions. The circuit is not really critical, but the board layout should be followed as closely as possible for best results.

Bypass capacitor C2 is a modified 270-pF feedthrough type. Both ends are snipped off as short as possible, then one end is soldered to the base of Q1 and the mounting ring is soldered to ground. Tuning capacitor C1, shown in Photo A, is a Johnson type U 189-502-5 1.3-6.7 pF air-variable. Later, it was found that a small tubular type such as a Centralab 829-3 .5-3 pF worked better. Using a tuning capacitor with an NPO temperature coefficient and metal film resistors reduces frequency drift due to temperature changes. Wire the remainder of the local oscillator as shown in Fig. 5(b).

The local oscillator is mounted in a small box fashioned from a strip of brass 3.2 cm (1¼ inch) wide and about 20.2 cm (8 inches) long. The board is suspended in the center of the box by soldering the edges of the circuit board to the center of the inside walls of the box. Holes for the B+ feedthrough capacitor, C3, and rf output coaxial cable are drilled, then the box is placed near the mixer as shown in Fig. 1 and temporarily tack-soldered in place. Make a cover for the box by cutting a 4.5-cm (1¾-inch) by 6.5-cm (2½-inch) piece of printed circuit board or thin brass. Drill a hole in it

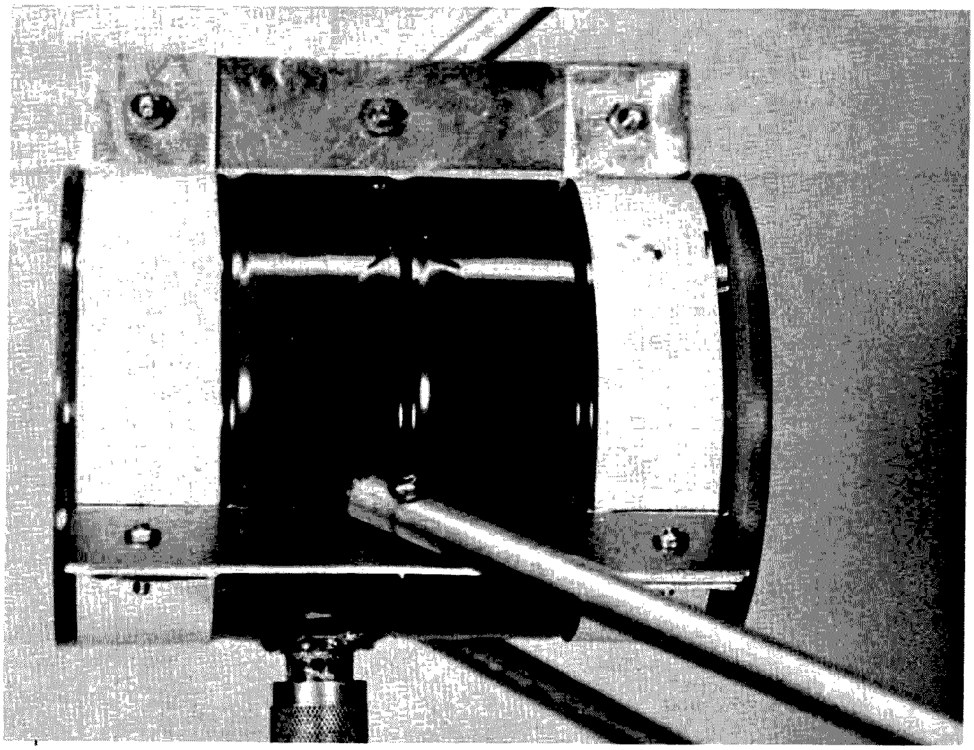

Photo F. Here is a close-up of the completed feedhorn and supporting hardware. Note the plastic radome cover is in place.

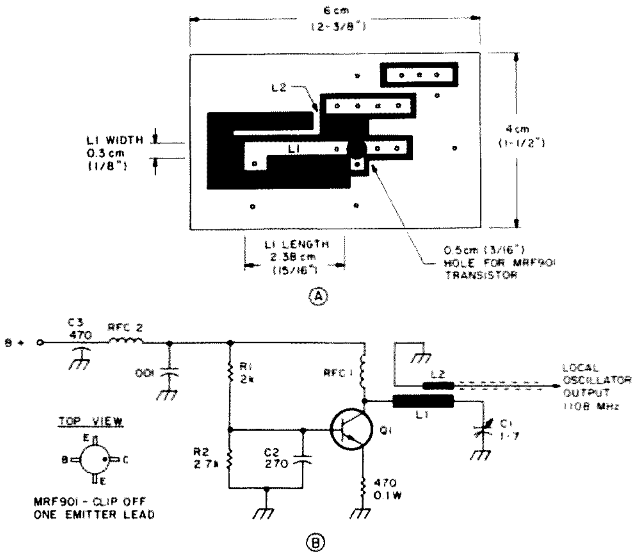

Fig. 5. (a) Bottom-view layout of local-oscillator circuit board. The shaded area indicates the area etched away. Use single-sided G10 epoxy circuit board. (b) Schematic diagram of local oscillator. Q1 is Motorola MRF901. RFC1, 2 is 13.5-cm (5¼-inch) #26 AWG close-wound, using a piece of #14 AWG as a mandrel. C1 is a 1-7-pF Johnson-type U (see text). R1 and R2 are ¼-W metal film-type resistors. C2 is a modified 270-pF feedthrough (see text) or other small low-inductance capacitor. This capacitor is soldered to the foil side of the circuit board to ensure short lead lengths. L1 and L2 are PC board inductors. Keep L2 as narrow and as close to L1 as possible. See Fig. 5(a).

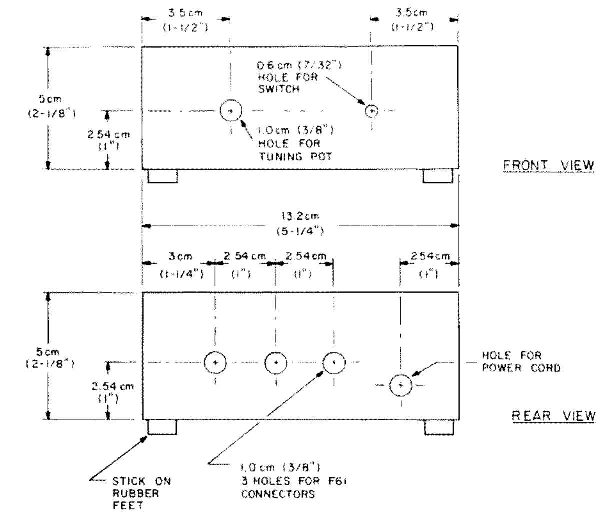

Fig. 6. Front and rear panel layout of the power supply/tuning unit chassis.

to permit access to tuning capacitor C1, and tack-solder the cover in place. Permanent attachment is not done until checkout and tune-up are complete.

Power Supply

The combination power supply/tuning unit is built into a 13.3-cm (5¼-inch) by 7.6-cm (3-inch) by 5.4-cm (2-1/8-inch) aluminum box. An LMB Tite-Fit chassis #780 works well. The box is drilled to accept mounting of the controls and type F61 coaxial connectors. The function switch is a DPDT subminiature, requiring a .6-cm (7/32-inch) hole. Holes for the coaxial connectors, the tuning pot, and the ac line grommet are 1-cm (3/8-inch). See Fig. 6.

The unit shown in Photo C was lined with double-clad printed circuit board. This was done in order to accommodate soldering to ground conveniently. This is a personal construction preference and certainly is not required. At this time, before the hardware is attached, the two-piece box may be covered with contact paper or painted as the builder desires. Small rubber stick-on-type feet are then attached.

Point-to-point wiring using Bakelite terminal strips was used in the unit shown. Follow the schematic in Fig. 4 and no trouble should be encountered.

Antenna Construction

The antenna design is shown in Figs. 7 through 10 and Photos D, E, and F. For the reflector bracket, you will need two 79-cm (30-inch) pieces of 1.27-cm (½-inch) aluminum tubing. Bend both ends of the pieces of tubing 90° to make the two U-shaped brackets as shown in Fig. 7. Use an electrician's ½-inch EMT conduit bender for this job, bending very slowly, and you will end up with a nice kinkless bend. Now, flatten about 1.9 cm (¾ inches) of each end of the two U-brackets in a vise and drill a .5-cm (3/16-inch) hole in the center of each of the flattened areas. Bend these flattened ends back at an angle that matches the contour of the outside edge of the back of the reflector.

Next, cut a 14-cm (5½-inch) by 16.5-cm (6½-inch), by .3-cm (1/8-inch) thick piece of aluminum plate. Drill a .5-cm (3/16-inch) hole in each corner and the four .64-cm (¼-inch) holes for the TV U-clamps. Center this plate on the two U-brackets and mark and drill four .5-cm (3/16-inch) holes in the U-brackets, matching the corner holes in the plate. Attach the plate to the brackets using four #10 bolts, nuts, and lock washers. See Fig. 7.

Now, hold the bracket against the back of the reflector, mark, and drill four .5-cm (3/16-inch) holes in the reflector, matching the holes in the flattened ends of the U-bracket. Attach the bracket to the reflector using four #10 bolts, flat washers, lock washers, and nuts.

The feedhorn is made from a one-pound coffee can measuring 10.2 cm (4 inches) in diameter by 13.7 cm (5-3/8 inches) in length. Drill a 1.3-cm (½-inch) hole 5.1 cm (2 inches) from the bottom of the can. Prepare a flange-mount type N or BNC connector (remembering that this is a microwave antenna, and SO-239/PL-259 connectors will not work) by soldering a 2.9-cm (1-1/8-inch) by .5-cm (3/16-inch) piece of copper or brass tubing to the center pin. Solder this connector into the hole previously drilled in the can. Soldering the connector to the can is recommended for both electrical and mechanical integrity. (See Fig. 9.)

Before mounting the feedhorn to the reflector, it

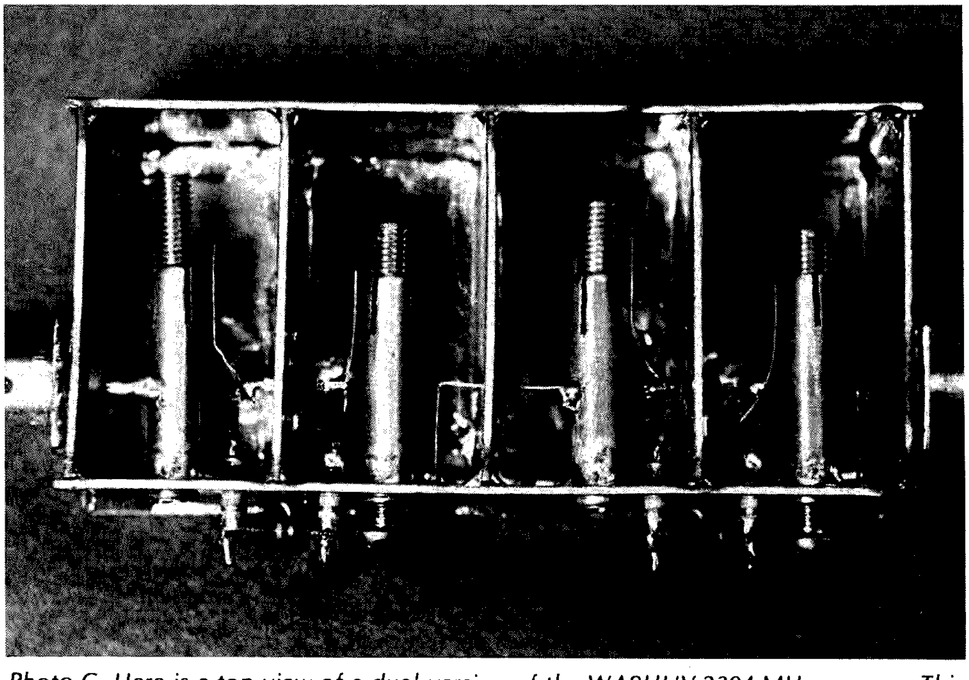

Photo C. Here is a top view of a dual version of the WA9HUV 2304-MHz preamp. This preamp covers the MDS band with no modifications. Note the L-shaped coupling link passing through the center partition.

should be given a thorough paint job inside and out. Don't paint the rf connector, the dipole, or the plastic cover. A good quality, anti-corrosion exterior metal paint should be used.

The feedhorn is held over the focal point with a three-legged support. The legs are made from three pieces of 1-cm (3/8-inch) diameter aluminum tubing 38 cm (15 inches) long. One end of each leg is flattened 1.3 cm (½ inch) back, and a .3-cm (1/8-inch) hole is drilled in the center of each flattened area. Drill a .3-cm (1/8-inch) hole in each of the legs 1.27 cm (½ inch) from the opposite end and 90° around from the first hole. Bend the flattened ends back to about a 45° angle. See Fig. 8.

In order to attach the supporting legs to the feedhorn, two straps are made of thin aluminum flashing material. Two strips, 2.5 cm (1 inch) wide by 46 cm (18 inches) long are bent and drilled, as shown in Fig. 8. These straps are wrapped around the can and tied together, using three 12.7-cm (5-inch) by 2.5-cm (1-inch) pieces of .16-cm (1/16-inch) aluminum sheet. Six 2.5-cm (1-inch) square pieces of the same material are used as washers, and #8 hardware is used to hold it all together. The supporting legs are then bolted between the reflector and the strap ties, using #8 hardware. See Fig. 10.

All of the hardware used in this antenna should be of the plated type to assure long life; you wouldn't want the thing to fall apart while you're watching something good on the tube.

The open end of the can faces the reflector, and, for proper focus, should end up 28 cm (11 inches) from the surface of the reflector.

All of the dimensions used here are correct for the 63.5-cm (25 inch) aluminum saucer sled. Some adjustments may have to be made if a different reflector is used.

Care should be taken in choosing a mount for the antenna. The reflector presents a surface area of over .3 square meters (3½ square feet) to the wind. A 61-cm (2-foot) roof tripod fitted with a 3.2-cm (1¼-inch) mast should be able to withstand all but the strongest winds. Mount the antenna as low as possible above the tripod, and make sure all bolts and clamps are secure. If possible, mount the antenna in a wind-sheltered location that still has a line-of-sight view of the MDS transmitting antenna.

Final Assembly and Tune-Up

Attach the antenna and downconverter to the mast and set in a tripod as shown in Photo D. Connect a *short* piece of *good* coax between the feedhorn and the downconverter. We have found that Berk-tek brand ultra-flex RG-8X coax fitted with BNC connectors works well for this purpose. The remainder of the cabling uses RG-59/U coaxial cable and TV-type F connectors.

The system can be tuned up with little or no test gear. If you are lucky enough to have a signal generator that covers 2.15 GHz, by all means use it. But, if you are like the rest of us, you will have to get by without it.

The tune-up steps will be to first check out the power supply, tune the oscillator, and peak up the i-f amplifier. This tune-up requires a location that is line-of-sight to the MDS transmitter, easy access to the downconverter and antenna assembly, and a TV set.

Don't attempt tuning up the downconverter on your roof or tower. Play it safe!!

Ensure that the power supply is operating properly by measuring the output voltage. It should be adjustable from 12 to 17 volts by varying the tuning pot, R2. This check should be done before applying power to the downconverter.

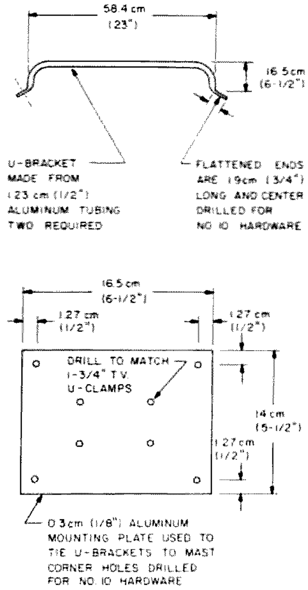

Fig. 7. Construction details of the U-brackets and mounting plate.

I-f Amplifier Tuning

Tuning the i-f amplifier is

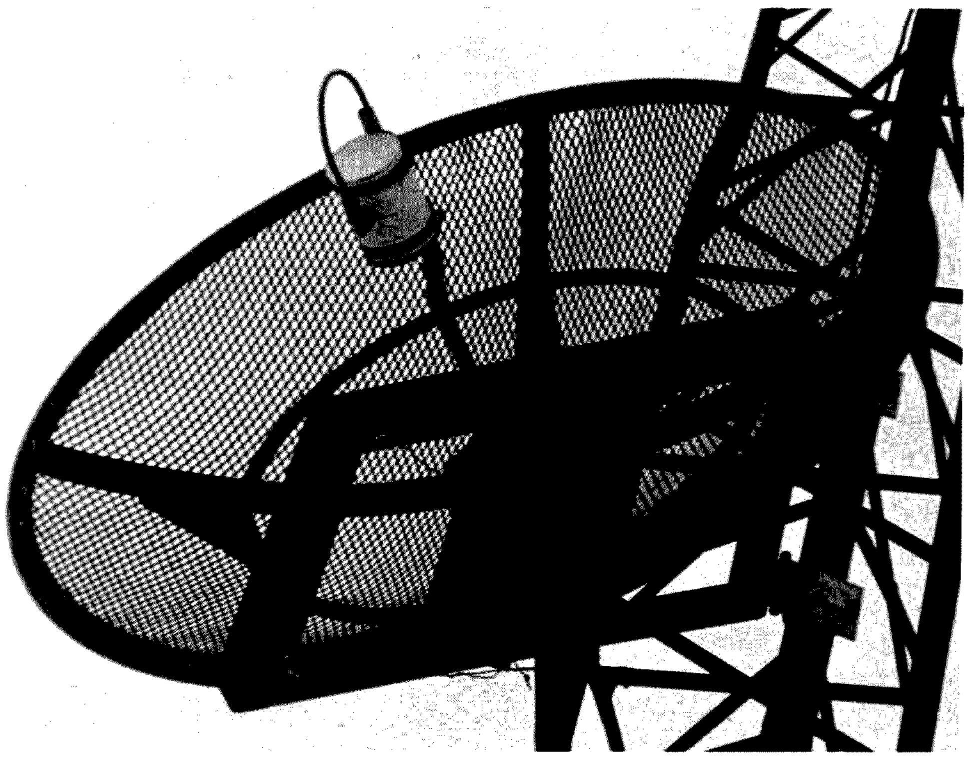

Photo H. This is a 122-cm (4-foot) commercial dish using a WA9HUV coffee can feedhorn. This antenna is used for MDS reception in a marginal signal location.

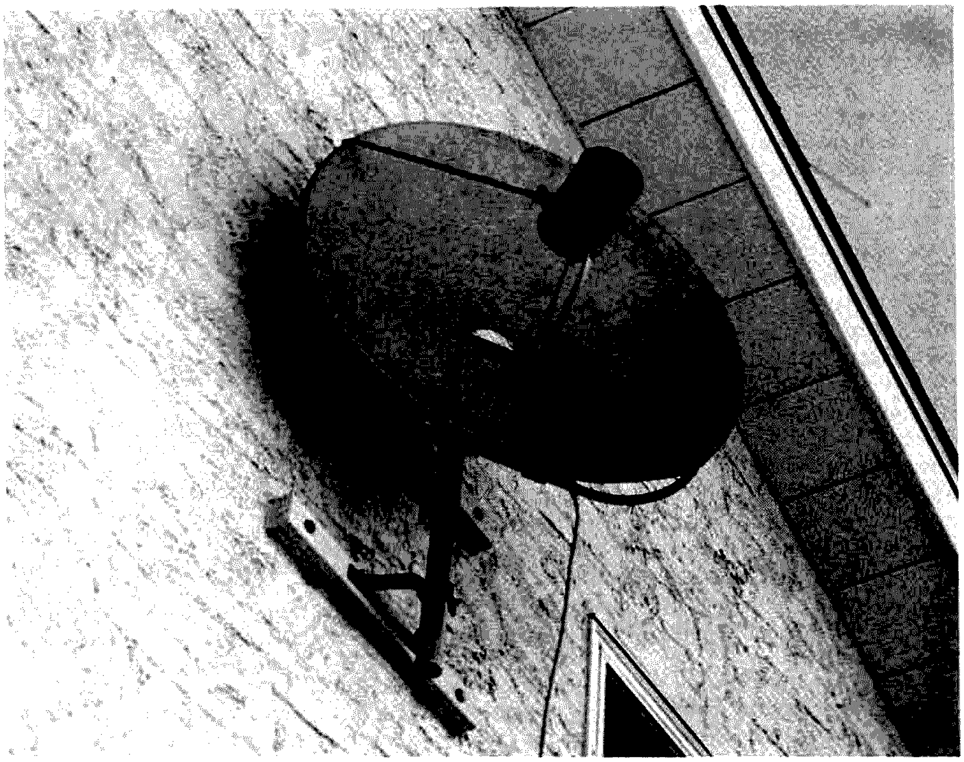

Photo 1. This is a 74-cm (29-inch) commercial reflector using a WA9HUV coffee can feedhorn. Located 4.5 meters (15 feet) high, this antenna pulls in snowfree color MDS TV signals over a distance of 32 kilometers (20 miles).

quite simple. First, you must choose which TV channel you will be using in your system. This should be channel 2, 3, or 4. It should not be in use in your area. Inject a signal into L5 from a signal generator or a grid-dip meter. The signal frequency should be 57 MHz for channel 2, 63 MHz for channel 3, or 69 MHz for channel 4. On the output of the i-f amplifier, use an rf probe or a series diode and a .001-uF capacitor to ground. Peak all coils (L5, L6, L7, L8) for maximum voltage across the .001-uF capacitor.

If you do not have a signal source at the i-f frequency, then set the slugs in all of the i-f coils halfway into their windings. Once you have completed the oscillator tuning, you can use the MDS signal for peaking up the i-f coils.

The local oscillator frequency required when using channel 2 as an i-f is 1105 MHz, for channel 3 it is 1108 MHz, and for channel 4 it's 1111 MHz. Set the power supply tuning control to midrange. Set switch S1 to the MDS position. Using an insulated tuning wand, adjust C1 to the proper frequency. If you have a frequency counter or spectrum analyzer that covers the LO frequency, use them. We have found, however, that using an off-the-air signal and adjusting for a good TV picture is the fastest and most sure way to accomplish this.

While tuning C1, you will probably see all sorts of strange patterns on your TV screen along with two or more settings that produce a standard TV picture. The tuning range of the LO is enough so that both the signal that we want and its image can be tuned in. Tune C1 to the higher of the two, which is the setting when the plates of C1 are the least meshed. The tuning control in the power supply can now be used for fine tuning. In the event that C1 shows no effect, you can test the oscillator for activity by using the signal sniffer shown in Fig. 11.

Preamps

There undoubtedly will be some locations that will have marginal signals. If, after having built the system, you find that your signal is snowy, you may wish to improve it with a preamp. There have been several good articles about 2304 preamps in the ham publications in recent years. The one that appears easiest to build is in the July, 1974, *Ham Radio*, by WA9HUV.[15]

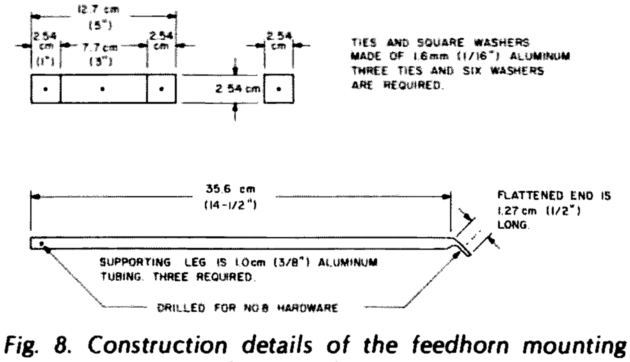

Fig. 8. Construction details of the feedhorn mounting straps, strap ties, and support legs.

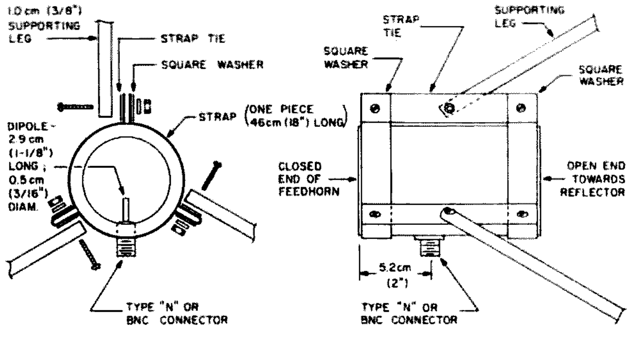

Fig. 9. Feedhorn mounting details.

You will find that most of the transistors the article recommends run from $17.50 to $70.00 each. As you can see, this could get expensive, especially if you need two or three preamps in series for more gain. What we have done is change the transistor to a MRF901, which costs $1.44. This device has less than a 3-dB noise figure at 2 GHz, but only about 6 dB of gain. Now, 6 dB of gain when you have a snowy picture does not help much. For a location that is marginal, we have built two of these preamps in the same box. That gives about 12 dB of gain and also eliminates the need for two connectors. At this frequency, too many connectors in the line can add a lot of loss and is expensive. I am sure it would be possible to build more stages into one box if needed, but we have not yet tried this. We have had up to three of these double preamps together with short cables. This worked well and gave a lot of gain.

We built most of our preamps using double-sided printed circuit board. This is faster and much easier than brass. Be sure to solder together intersecting edges on the inside where possible. At this frequency, a good rf-tight box is desirable. WA9HUV's article gives two possible circuits depending on what kind of transistor is used. When using a MRF901, use the circuit on page 8 of the article, which is labeled Fig. 1. We show the method of coupling two stages together in Photo G here.

The preamp should be mounted as close to the feedhorn as possible, and it also will need to be enclosed in a weatherproof box. Power tapped from the downconverter can be used to power as many preamps as are found to be necessary.

Conclusion

In this article we have shown you details for building a cheap and easily-reproducible MDS receive system. Most of the circuits and ideas have been gleaned from previous construction articles and manufacturers' applications notes, so no originality is claimed. Although the system as described performs very well, if you find that you can make any significant improvements to the systems, we certainly would be interested in hearing of them.

Since the original design of the system, printed circuit boards have been laid out and are now being made. These boards, along with some of the harder-to-find components and complete antennas, are available from the authors. Send an SASE for details. ■

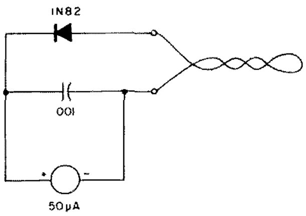

Fig. 11. A piece of test equipment called a signal sniffer. It can be used to tell if the oscillator is working. The meter movement should be a good quality 50-uA movement. The diode is a 1N82 or other high-frequency diode, and the pickup loop is about twelve inches of #22 hookup wire twisted together with a one-inch loop at the end. This sniffer works to 2 GHz or more.

Simple Dual-Voltage Supply

—power for many projects

A welcome addition to any shack.

E. E. Buffington W4VGZ
2736 Woodbury Drive
Burlington NC 27215

Why doesn't someone tell parts distributors and transformer manufacturers that *nobody* designs tube circuits anymore, let alone *builds* them. Catalog pages are full of filament transformers and they are being bought because nothing else is available. Manufacturers seem to be rushing to resupply this so-called great demand.

There are two dc voltages that I generally need supplies to provide: +5 volts for TTL and +13.6 volts as a car battery eliminator. A 12.6 V ac filament transformer will not work well for these dc voltages. Those of you who have tried were frustrated, I'm sure, by the attempt.

Take the +5-volt supply, for instance. Okay, full-wave rectification with the c-t grounded will yield a peak dc on the filter capacitor of $(6.3 \times 1.414) - 0.5 = 8.4$ volts. Now, an LM309K needs +7 volts to regulate (a 2-volt regulator margin). This means that the maximum ripple is 1.4 volts. Let's say you need 1 Amp from this supply and you chose a 1- or 2-Amp transformer. Now, to get the ripple to less than 1.4 volts, you start to pile on the capacitance and the full-load ripple comes down. Then as you add more capacitance, the ripple goes up! What is going on here? As you add more capacitance, the phase angle over which you draw current decreases. This means that you are not continuously drawing 1 Amp from the transformer, but, instead, you are drawing many Amps over a short time to yield a continuous load current of 1 Amp. Transformer core saturation and winding resistance drops are causing the problem. The truth is that this transformer will not work except for small currents. The +13.6-volt supply using a bridge rectifier will yield the same picture—not enough margin for the regulator to operate. The next highest filament transformer is 24 volts—too much voltage and too much power to be thrown away via the heat sink.

A switching regulator, Fig. 2, has some advantages inasmuch as the utilization of transformers is concerned. The pulse width is varied to the pass transistor to control the output voltage as the load current changes. The efficiency can be very high with this configuration. The disadvantages are formidable. Switching transients clutter up the spectrum so that much shielding and filtering is necessary. Transient load changes may generate output voltage variations amounting to ±20 percent or more. As you might gather, I don't recommend this circuit for the ham shack.

What we *really* need in a transformer is 18 V c-t. This voltage is perfect for both the +5-volt and +13.6-volt supplies. Few distributors stock them so you really have to look around. Fig. 1 shows a couple of ways to connect filament transformers to furnish the required voltage.

Fig. 3 shows a really great supply that uses easy-to-get parts. I have included the Radio Shack part numbers for your convenience.

Now, a word about the filter capacitor. It is as important not to have too much capacitance as it is to have too little. You should select a capacitor so that at maximum current you have enough margin for the regulator to work. In the circuit of Fig. 3, C1 is selected so that the ripple voltage is 5 or 6 volts. This allows the transformer to furnish the 3 Amperes of output current over a much wider phase angle. I have used the for-

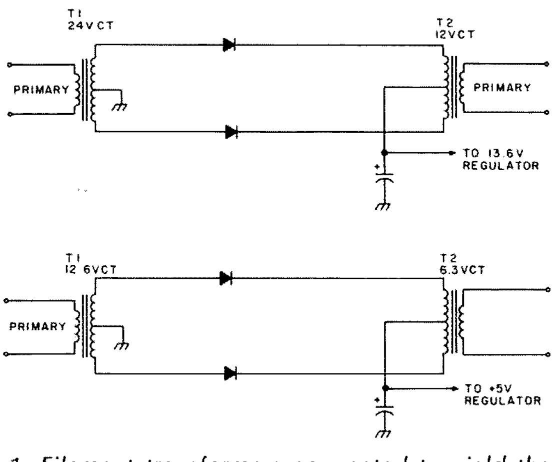

Fig. 1. Filament transformers connected to yield the required input voltages to the regulator.

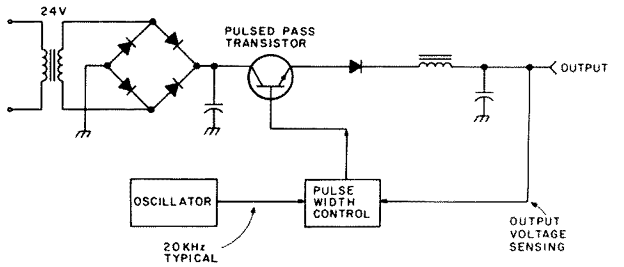

Fig. 2. Switching regulator showing basic functional blocks.

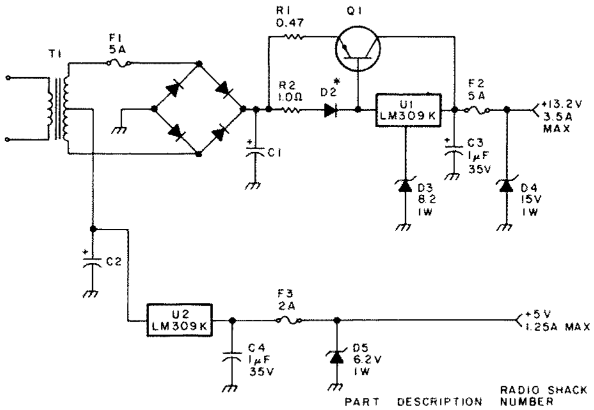

PART	DESCRIPTION	RADIO SHACK NUMBER
T1	18VCT 4A	273-1514

Fig. 3. Power supply using easy-to-find parts.

mula E = I/120C with good results. E is the peak-to-peak ripple voltage, I, the dc current in Amperes, and C, the filter capacitor in farads. This formula is not exact but should be quite close for most applications.

Resistors R1 and R2 in the circuit of Fig. 3 cause the current to divide between the regulator and the pass transistor. For three Amperes at the load, two will flow through the pass transistor and one through the LM309K. If you use a germanium pass transistor, you can omit D2, as D2 compensates for the base-to-emitter junction voltage drop of the pass transistor. Zener diodes D4 and D5 form an overvoltage protection that will blow the output fuse in case of a regulator failure. If you don't put in this protection, you'll be sorry! An insulating washer is needed for U1 as the case is above ground by the drop across D3. The case of U2 can be bolted to ground. Use a common heat sink having a thermal resistance to ambient of less than one degree per Watt. The addition of panel meters to monitor the current would be a nice improvement. The fuses would not be expected to blow as the power supply is protected against short-circuiting and overload. Of course, you can't load both regulators to their full capacity at the same time, as this would overload the transformer.

This power supply should be a welcome addition to any ham shack.■

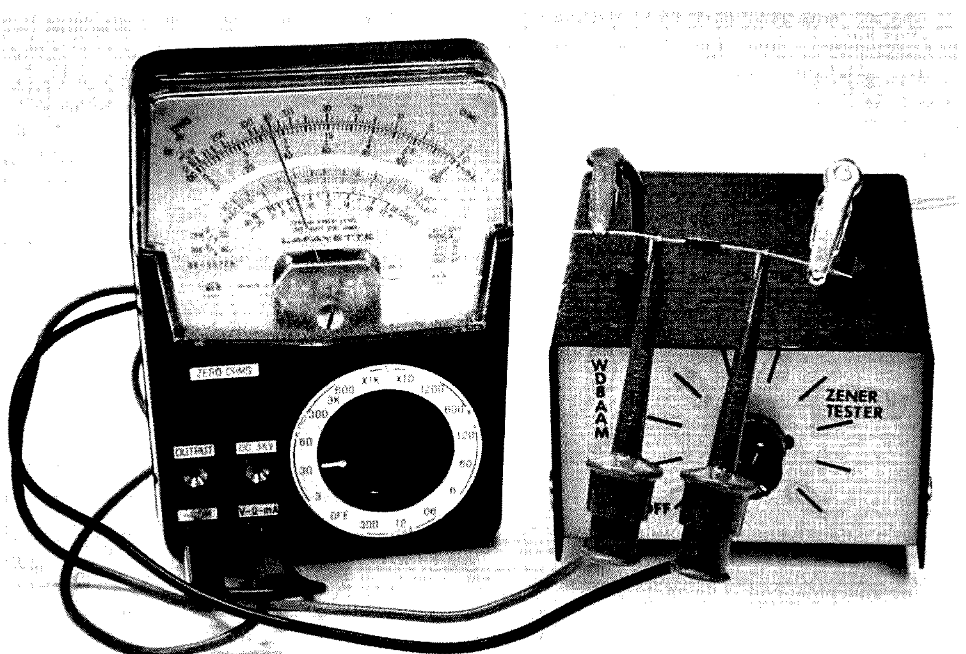
Bargain Zener Classifier

—Novice project

Enjoy.

Some time ago, I was building a low-voltage power supply which used a zener diode to regulate the base current of the regulator power transistor and found I didn't have the proper zener in my junk box. Checking my local parts store, I found that a single zener of the voltage I needed was about twice as expensive as a package of 20 miscellaneous zeners I had seen at my local Radio Shack store. As always, my frugal nature suggested I get the most for my money, so I built a simple circuit, which I am going to pass along, that enabled me to check the zener voltage of each diode.



Unit with a zener diode being tested and showing proper hookup to the VOM. Note that the VOM is indicating 8.6 volts even though the tester voltage output is 28 volts. Don't forget to set the VOM to measure dc voltage. It doesn't show up very well in the photo, but I used red wire for the plus alligator clip and black for the negative. These wires were then inserted into 2 phone tip jacks on the top of the case.

Simplicity

The circuit is as simple as they come. Follow Fig. 1 and the photographs and you should have no problem building a useful gadget which comes in very handy almost 90% of the time you build a new project. Looking at the schematic, you'll notice the power transformer is very important as it isolates the circuit from the ac line for safety. Next, the diode rectifies the ac into pulsating dc. The following 120k resistor drops the voltage to the potentiometer. The electrolytic capacitor smoothes out the dc ripple to provide a dc voltage of about 30 volts to the alligator clips. (It's the next thing to an instant project.)

Using the Tester

Place the cathode (the

end with the band) of the zener that you wish to classify in the plus voltage alligator clip, connect the VOM, as shown in the photograph, run the voltage up until the VOM needle stops, and that's the zener regulating, or breakdown, voltage. If you connect the zener backwards in the circuit, you should get very little, if any, indication on the VOM meter because the diode is conducting and presents a short circuit to the tester. This circuit passes very little current through the zener under test, so you shouldn't have any problems with zener burnouts.

If, after classifying all your diodes, you still don't have the correct value, try putting two or three of them in series. When I built my power supply, I needed a 12-volt to 13-volt zener. I put an 8.2-volt and a 4.3-volt zener together in series to obtain 12.5 volts and, because of this, I could also tap at the junction of the zeners to obtain a regulated 8.2 volts.

You'll find that regular diodes and transistors have a zener action as well. Although voltage values will be random and current capabilities small, they can often be used in place of a regular zener diode. When the transistor is bad anyway, it beats throwing it away.

You'll notice all parts have a wide tolerance, so you can use any of the old parts you may have in your junk box. Enjoy yourself.■

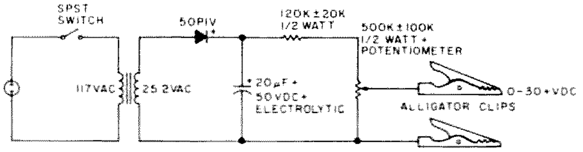


Fig. 1. Zener tester.

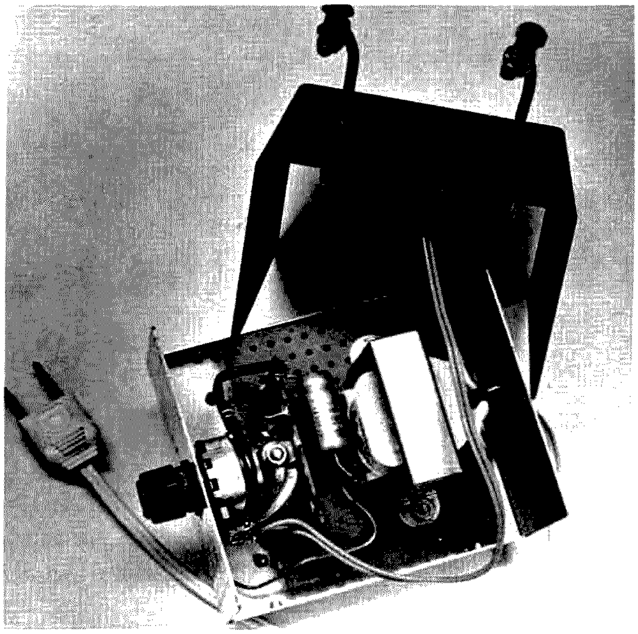

Interior view. All the parts came from my junk box with the exception of the case and power transformer which are Radio Shack stock items. A small piece of perfboard was used to mount the parts, and spacers were used to lift the perfboard off the metal chassis.

What the Hell is a Decibel?

—1/10 of a bel, of course

Rationalizing the ratio.

I have always had a difficult time dealing with decibels. It is important to remember what a decibel is and what it isn't. First, the decibel (dB) is, itself, not a measure of anything. It is not a unit like a volt or an Ampere. Hams often have a problem with this. It is not a measure of the loudness of anything, nor is it the measure of the power in any signal.

The decibel is a ratio—that's all. It is ten times the base 10 logarithm of the ratio of two power levels.

Voltage (Current) Ratio	Power Ratio	dB
.32	.1	−10
.45	.2	−7
.50	.25	−6
.71	.50	−3
.89	.79	−1
1.00	1.00	0
1.12	1.26	1
1.41	2.00	3
2.00	4.00	6
2.24	5.00	7
3.16	10.00	10
4.47	20.00	13
7.07	50.00	17
10.00	100.00	20
14.14	200.00	23
22.36	500.00	27
31.62	1000.00	30

Table 1.

So a decibel only has meaning with reference to some other power. For example, 100 Watts bears the same ratio to 10 Watts as 10 Watts bears to 1 Watt. The ratio in each case is 10 to 1. Any two power levels having the ratio of 10 to 1 would have the same number of dBs relating them.

The basic unit is the bel. The bel is defined as: $n = \log (P1/P2)$, where P1 and P2 are the two power levels being compared and the base 10 logarithm is used.

The decibel is 1/10 of a bel, so there are 10 dB per bel, and: $m = 10 \log (P1/P2)$. You already know the equations for power: $P = IE$, $P = E^2/R$, and $P = I^2R$, where I and E are the current through and the voltage across the resistance, R.

Now, with a little fancy footwork and algebraic substitution, we can come up with the following: $m = 10 \log (E1^2/R1)/(E2^2/R2)$, which can be further reduced to: $m = 10 \log (E1^2/E2^2)$, *if and only if* $R1 = R2$. Further reduction yields: $m = 20 \log (E1/E2)$.

Using a similar process, we can derive the following equation: $m = 20 \log (I1/I2)$, and, tra-la! We have our complete set of equations for the mysterious decibel. The important thing to remember is that for the two equations involving voltage and current, the resistance that the voltage is across or that the current flows through must be identical for the two values to be compared. Otherwise the calculation is invalid.

Don't try to think in terms of a set of dB ratios for power as separate from a set of dB ratios for voltage. All ratios are in terms of power, and, since you already know that the power goes as the voltage (or the current) squared, you can deal with either quantity.

Table 1 lists working voltage (also current) and power ratios for various dB ratios. Note that the voltage-ratio numbers are simply the square roots of the power-ratio numbers.

The decibel is used for any one of three reasons depending upon which reference book you believe. I've added a fourth reason.

1. One decibel is the smallest perceptible change in loudness detectable by the human hearing system. The human ear is a logarithmic device and the decibel is a logarithmic number, so there is a better correspondence between the perceived loudness ratio and the decibel.

2. The decibel is used to express large ratios of powers with small numbers. For example, 30 dB is a power ratio of 1000.

3. The decibel is used so that any change in power by the same ratio will have the same decibel ratio. For example, a change from 1 to 2 Watts is a 3 dB change, as is a change of from 1000 to 2000 Watts. The effect on communications of these changes in levels will be the same.

4. The decibel is used to confuse radio amateurs.

OK, where are these dastardly decibels foisted on an unsuspecting amateur radio operator? Probably the most common use of the decibel in amateur radio is in relation to your receiver S-meter. The

S-meter is usually calibrated in S-units from zero through nine and then in dB above S-9. S-9 is supposed to correspond to a signal level at the receiver antenna terminals of 50 microvolts (although it rarely does). Each S-unit corresponds to 6 dB, so S-8 is 50 microvolts minus 6 dB. Refer to Table 1 or do the following calculation: $-6 = 20 \log (E1/50\ uV)$, $E1 = (50 \times 10^{-6}) 10^{-6/20}$.

This reveals that the signal level at the antenna terminals is now 25 microvolts. The calculation above is valid because the antenna input impedance of the receiver does not change. The denominator of the ratio is always the reference amplitude. So, every S-unit down corresponds to about one-half of the voltage at the antenna terminals of the S-unit above it.

Likewise, if the meter reads 10 dB above S-9, the voltage at the antenna terminals is 10 dB higher than 50 microvolts. $10 = 20 \log (E1/50\ uV)$; $E1 = (50 \times 10^{-6}) 10^{10/20}$.

This corresponds to a received signal of 158.1 microvolts. The unfortunate fact is that most receivers don't have S-meter readings which are significant in any absolute sense—about all you can tell is which signal is stronger at your QTH.

Another common use of the decibel is in the measurement of antenna gain. The important thing to note here is what kind of antenna is used as a reference. Remember that the decibel is only a ratio and that the goodness of an antenna as measured in decibels is only a goodness relative to some other type of antenna. The two most common reference antennas are the isotropic antenna and the dipole antenna. The isotropic antenna is a theoretical model of an antenna which radiates equally well in all directions. Dipoles are, of course, real antennas that have a radiation pattern which is not everywhere identical.

When talking about the gain of an antenna, we are talking about the increased power radiated in its direction of maximum radiation compared to the power radiated in the direction of maximum radiation for the reference antenna. Obviously no additional power is "generated" by the antenna. What the antenna does is tend to concentrate the available power in one direction at the expense of all other directions.

If the gain of an antenna is given in dB over isotropic and you want to know the gain of the antenna relative to a dipole, subtract 2.1 dB from the figure. Similarly, if you have the gain of an antenna over a dipole and you want to know the gain of the antenna over an isotropic antenna, add 2.1 dB. This follows from the fact that the gain of a dipole antenna over an isotropic antenna is 2.1 dB.

It is important to know that decibels can be added or subtracted as the gain of the system is increased or decreased. For example, say your transmitter puts out 1 Watt and that an amplifier boosts it to 10 Watts—that's a gain of 10 dB. Now, suppose you have another amplifier that boosts the signal to 500 Watts—that's 17 dB additional. So the total gain of the amplifiers is 10 dB + 17 dB = 27 dB.

Now, suppose you have an antenna with a gain of 12 dB over isotropic and you trade it in for an antenna with a gain of 18 dB over isotropic. You've bought yourself 18 dB − 12 dB = 6 dB gain.

Another antenna-related use of decibels relates to coaxial feed cable. You may be surprised to learn that the loss in RG-58/U coax is 6 dB per 100 feet at 150 MHz, and the loss in RG-8/U coax is less than 2.5 dB per 100 feet at 150 MHz. This means that if you're using a 10-Watt transmitter through 100 feet of RG-58/U, and you're operating on 150 MHz (out of the band), the power delivered to the antenna will be 2.5 Watts. The same setup with RG-8/U coax will deliver 5.6 Watts to the antenna—this is 3.5 dB better performance. So, as you can see, those dBs can sneak up on you.

Perhaps the most common use of the decibel is in the measurement of sound levels. I have heard, on occasion, people refer to a sound-pressure-level meter (SPL meter) as a "dB meter." There is no such thing. The SPL meter indicates the sound pressure relative to a reference acoustic pressure of .0002 microbars. So, 100 dB SPL is, in fact, 20 microbars of acoustic pressure. (Acoustic pressure is analogous to electrical voltage.)

It can be useful to practice some calculations using decibels. A good working knowledge of the use of the decibel can keep you from feeling left out the next time someone brags about his antenna with 10 dB gain. ■

Frosting for the FT-901DM

—simple improvements for Yaesu's superb performer

Dave Ingram K4TWJ
Eastwood Village, #1201 South
Rte. 11, Box 499
Birmingham AL 35210

One of the hottest and most exciting rigs presently on the amateur market is Yaesu's FT-901DM transceiver. The outstanding performance of this "no compromise" unit is rivaled only by the enthusiasm, interest, and technical prowess of its stateside representatives and distributors.

Before delving into the collection of 901 modifications I've gathered via several sources, I must emphasize that this unit is a star performer as it stands, and you can expect long-term enjoyment regardless of your decision whether or not to try any of these options. I'm complimenting the rig, not discrediting it in any way.

Speech Compressor

The FT-901DM's speech compressor does a superb job, but its response is tailored for high-pitched Japanese voices rather than the lower-pitched American voices.

If you would like to see the speech compressor become a real tiger, change C218 on PB1703 from a 100 pF to a .01-uF mylar™ or paper capacitor. PB1703, the ALC/speech compressor board, is located third from the rear on the rig's left side. C218 is located on PB1703's bottom center, and its solder connections are almost directly beneath the clear plastic-insulated jumper on the circuitry side of this board. This modification extends the compressor's low frequency range and allows it to operate more efficiently.

While discussing audio response of the 901, I might also suggest that amateurs searching for a quality mike try the Shure 526 (less transistor preamp) with the 901. I've tried a bundle of mikes with mine, and this one performed head-and-shoulders above all others.

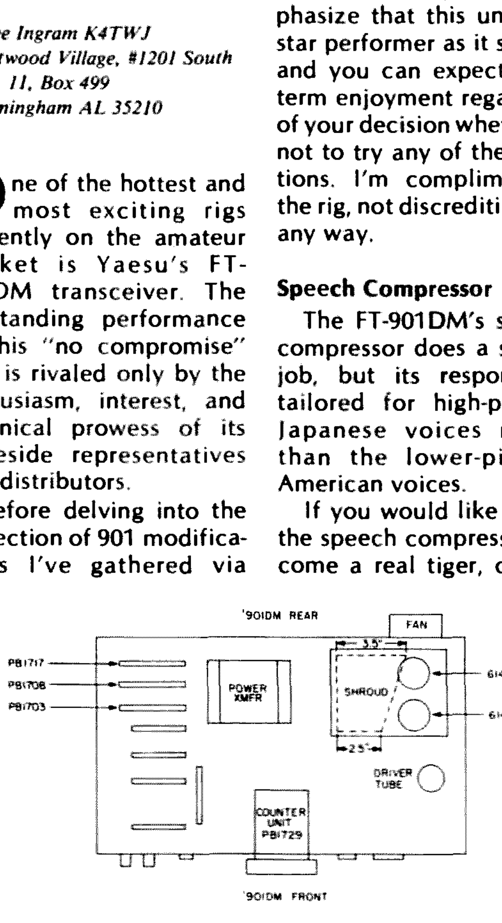

Fig. 1. Placement of 6146B cooling shroud and printed boards, as described in the text.

ALC

If you would like smoother ALC action (or if you've been concerned about meter readings in the green part of the ALC scale), this simple modification will ease your mind and produce very good results. Remove the 901's bottom cover and locate the socket for board PB1703. Connect a 68k, ¼-Watt resistor between the ground and pin 16 of this socket, then bypass the resistor with a 2.2-uF tantalum capacitor.

This is a good time to tweak dot-dash ratios on the Curtis Keyer, if desired. The keyer's PC board is also located on the 901's bottom side.

Low 40-Meter Output

If your 901 produces an output of less than the usual 100 to 120 Watts on 40 meters, try this simple procedure. Add a .01-uF 500-volt disc capacitor from C22 to ground. C22 is a feedthrough capacitor located in the power supply.

Flickering LEDs

The memory LED in some 901s (located above the digital frequency readout exhibits a very slight flicker when the unit is originally turned on and a frequency isn't loaded in

memory. There are two simple solutions to this situation: 1) Simply tap the memory button and load a frequency into memory, or 2) change C61 on the memory board from .33 uF to 4.7 uF. A tantalum capacitor is suggested.

Fan Noise

Since I'm accustomed to the total silence of Rotron Whisper fans, I found the Yaesu fan a mite loud for my sensitive ears. A close inspection of the fan revealed a slightly off-center armature. This situation was visible when holding the fan proper up to the light and looking through its rotating armature to assure symmetrical alignment. I found the most accurate way to adjust this fan involved carefully applying 110 volts to the removed fan and slowly positioning its armature for minimum noise. If you prefer an absolute death-quiet fan, Rotron's small Boxer fan can be substituted here. The fan in my 901 may have been one in a hundred, so use your own discretion with this modification. Fortunately, this fan unplugs and unbolts from the outside of the 901's rear, so you need not open the rig for this modification.

Cooling Shroud For 6146B Finals

While the Japanese are very proficient in electronic technology, they seem somewhat limited on air ducting and cooling techniques. Erskine Jackson W4CEC solved this problem quite easily. He cut a triangular sheet of aluminum 2.5 inches by 3.5 inches and installed it above the final amplifier compartment as shown in Fig. 1. This shroud prevents "short circuit" air being pulled from atop the tube compartment and alternatively pulls it *across* the 6146Bs from the compartment's sides. This superb technique also has been used with Kenwood gear.

6146 Finals

A problem has been noted with the GE-brand 6146Bs installed in many 901DMs. The screen grid would fall against the plate and apply +900 volts to the +210-volt screenline. Yaesu recently switched to Toshiba 6146Bs and this problem has been eliminated. If your 901 has GE finals, you would be wise to make this switch also. Pursuing this situation a step further, Yaesu has developed a modification to protect the 210-volt supply from this problem. Here's the information:

Install a diode as shown in Fig. 2. This is included in lots 006 and higher, with lot 007 using a new etch pattern that includes this modification.

Modification: (1) Remove the bottom cover on the FT-901; (2) attach a soldering post to the chassis with a tapping screw as illustrated; (3) solder a 10D10 diode to the post—*note the diode polarity*; (4) remove the yellow wire from the printed circuit board (PB-1715A) and solder it to the diode installed in step 3; (5) connect the other end of the diode to the printed board where the yellow wire was removed; and (6) replace the bottom cover.

Reducing Excess Baggage

Most of the 901's heat is generated in its left back corner. This heat comes from the bleeders on top of PB1717 and from the choke and components on PB1708. Since several capacitors and resistors are physically located above the choke on PB1708, they may become hot and change value and eventually fail. Realizing this problem, Yaesu suggests R13 (47k, ½-Watt) and R03 (470 Ohms, 1 Watt) on PB1708 be changed to the same resistance in 2-Watt resistors. Further investigation of this particular circuit revealed that its only function is as part of a filter section for a 160-volt line going to the 901's rear accessory jack. Since W4CEC and I have no immediate plans to use this jack, we disconnected our circuits by pulling one end of diode D03 loose from the board. We also removed our black plastic "board cover" to permit air flow. The results have been quite gratifying, and our 901s now run quite cool, even when used for long periods of time.

Counter Protection

It has been found that capacitor C2954 on the counter unit (PB1729) was installed backwards in early 901DMs, and this may lead to failure in various segments of the digital display. You can quickly check this in your unit in the following manner. Locate the counter unit behind the digital display and pry up its snap-on cover. C2954 is a small, blue capacitor on the unit's left side. Its markings should face the rig's rear (toward the power transformer). If the capacitor's markings face the rig's front, simply remove and reverse it.

You'll gain a wealth of knowledge on 901 construction when investigating this modification. The enclosed PLL unit (PB1709) and the rf unit (PB1702) must be removed before the counter unit and digital display can be slid back and removed. All screws on these units stay intact when freed, thus eliminating the lost-screws-or-spacers dilemma. You'll also notice that the plug-in digital displays are readily available, inexpensive units.

Conclusion

The modular construction of Yaesu's 901 makes servicing a relatively simple task. Few rigs offer this capability. That fact, coupled with the large number of technically-oriented amateurs owning 901s, has resulted in the modifications presented in this article. It's logical to assume that additional modifications or improvements on this rig will continue the collection presented here. This leads me to believe that the original "Fox Tango Club" may soon reach its greatest days. The FT-901DM is the most outstanding rig I've ever owned or operated.

I would like to thank Bernie Tower W6RNW of Yaesu and Don Langston WB4JVY of Long's Electronics for their support and assistance with information concerning the FT-901DM. A special thanks to Erskine Jackson W4CEC for his ideas, suggestions, and assistance as we modified our 901s. Thanks also to my XYL, Sandy WB4OEE, for typing this article.■

Mods for the Mark

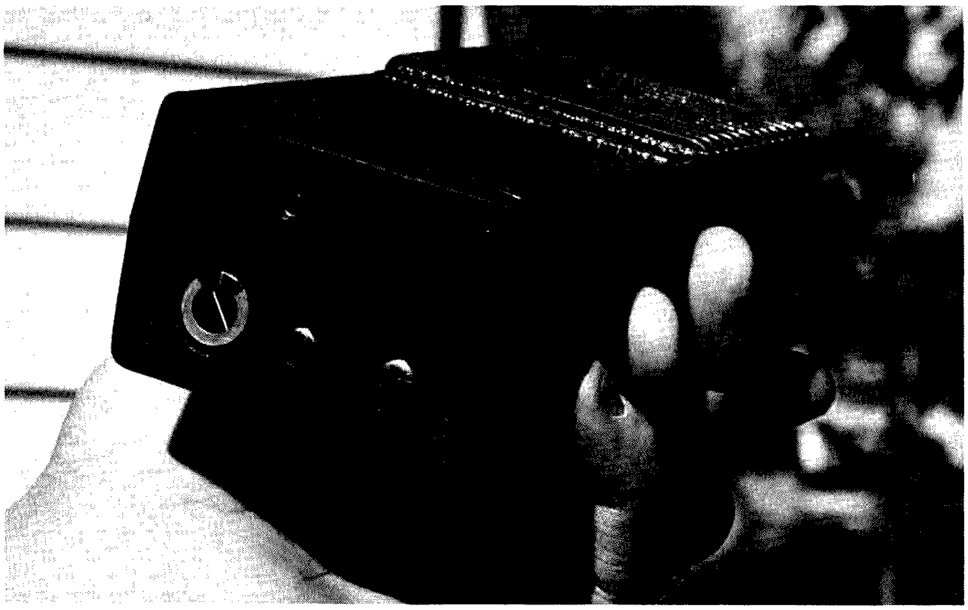
—desirable extras for your Wilson HT

Bob Heil K9EID
#2 Heil Industrial Blvd.
Marissa IL 62257

Many of the new Wilson Mark II handheld units are showing up on the many repeater systems. The HT is really a neat little package, but, as usual, it can be improved upon with a little ingenuity and time.

Battery-Level Indicator

The one thing that the Mark II really needs is a method for monitoring your battery level. Two systems can be used. The simplest is a new LED by Hewlett-Packard which has a comparator circuit built into a tiny LED. All you need is one resistor and a diode in series with it to set the threshold at your charged-battery voltage. Simply connect to the PTT line. Each time you transmit, the small LED will light. If it doesn't, your battery voltage has fallen off and caused the comparator not to turn on and light the LED. If you want, you can connect this comparator LED to the battery through the extra switch contacts on the squelch that Wilson provides for tone squelch additions. This new voltage-sensing LED is available from H-P as part #5082-4732.



S-Meter/Battery Level

I figured that since Wilson was nice enough to leave at least two square inches of circuit board space in the bottom of the Mark II for their optional tone squelch board, I would take advantage of this and build an S-meter circuit for receive and a battery-level indicator for transmit.

The meter used was purchased from Hy-Gain. It is the same one they used in their #3086 HT. It mounts in the bottom of the Wilson on that same little plastic end piece that houses the battery-charging contacts. This works out so that you

don't have to cut any holes in the main case. A touch of epoxy cement holds the little meter in place. Be sure to recess it a little so the HT will sit level in the charger.

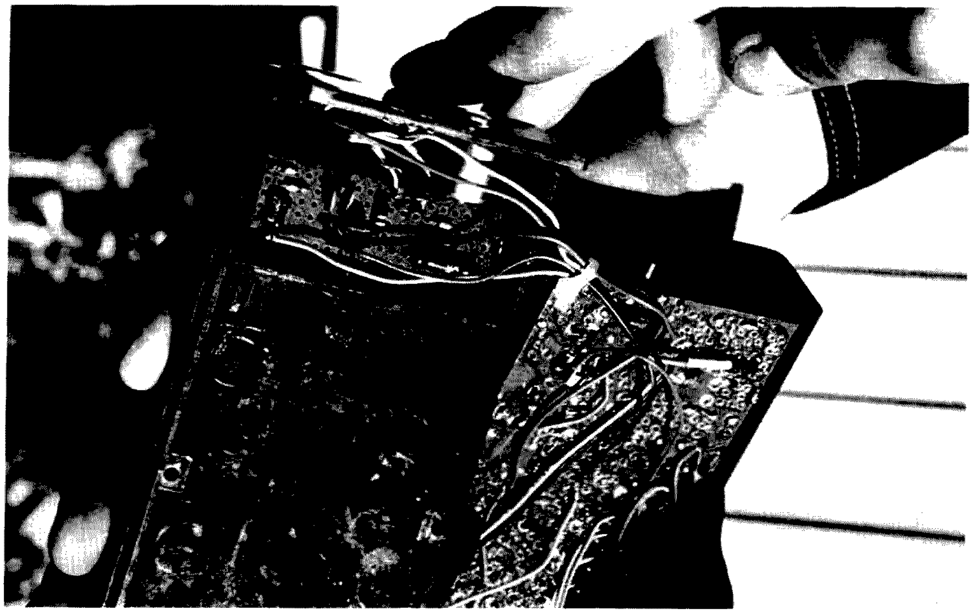
The S-meter circuitry is very simple. Just about any NPN transistor can be used as an amplifier to drive the meter. A part of the output of the second i-f amplifier is detected with D1 and fed into the meter amplifier.

The battery-level indicator circuit is simply one diode connected to the junction of two resistors to form a voltage divider off the PTT line. This allows the meter to function only during transmit. You also could connect the level meter circuit directly to the battery through that spare switch contact on the squelch control that was originally planned for a tone squelch circuit. Using this method, one can check the battery level at any time, not just during transmit. Personally, I prefer using the meter to monitor during my transmit periods since that is when the current drain is the heaviest.

Easy Construction

For the purists, a printed circuit board could be laid out, but with such a simple and small circuit, vectorboard can be used quite effectively. The board measures 2-1/4" × 7/8". Mount the parts, solder all connections, and leave about 5" of all wires so easy connections can be made to the main Wilson PC board. The only problem you may have is in making certain you observe the diode polarities. The rest is very straightforward, and it should all go together quickly and easily.

An easy method to secure the board is to use some small, 1/8"-wide tape along the sides of the board, and simply tape it in place. Works out great!



Only 4 Connections

The circuit board uses only four connections to the main circuit board of the Wilson: B+, ground, PTT line, and the receiver limiter. Extra sensitivity can be achieved in the S-meter circuit by adjusting R1. For transmitter hunts or weak signal hunting, you may want to play with the resistor.

Cut the four wires to their necessary lengths, trim, and solder in place. Your S-meter/battery-level indicator is ready for action!

External Headphone Jack

There may be times when you desire to use your Mark II with a small earplug so as not to disturb anyone else; install a micro-jack in that bottom plate so that the speaker line is disconnected when the earplug is plugged in.

Improving the Transmit Audio

Being in the professional audio business, I tend to be a bit "picky" about the audio we, as amateur radio operators, hear. After comparing the Mark II transmit audio to many other handheld units, it became apparent that improvement was necessary. The improvements are also very simple to achieve.

New Mic Cartridge

First and easiest is to replace the Mark II micro-

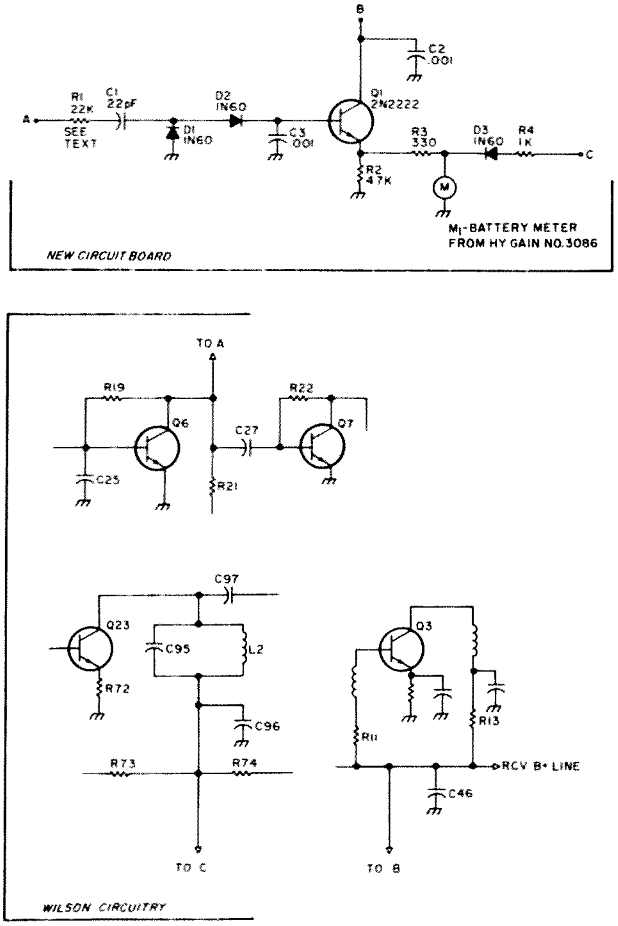


Fig. 1. Mods for the Mark. Pick-off points A, B, C are easily located by referring to p. 18, "Circuit Board Overlay," of the operating and service manual.

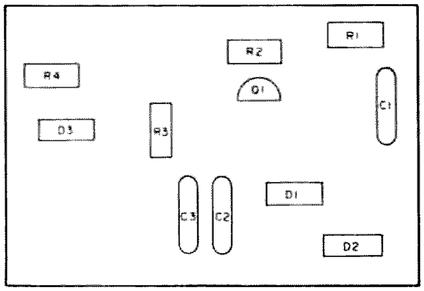

Fig. 2. PC card layout for Mark II. Complete kit with all components, PC board, and wire harness, but without meter (available from Hy-Gain) is $8.00 from Melco, P.O. Box 26, Marissa IL 62257.

phone with a Knowles BA1501 (Knowles Electronics, 3100 N. Mannheim, Franklin Park, Illinois 60131). This really helped the audio response as noted on an audio analyzer. A few component changes also are in order to achieve better audio. Change R78 from 3.3k to 1.5k, C111 from 0.1 to .47, and C118 from 0.15 to .47.

Try this audio mod and I can guarantee that your friends will think you are on a full-sized mobile transmitter! We might also point out to Mark II owners that by simply changing the driver transistor, Q24, to an MRF 515, you will have a Mark IV. Use care when tuning the collector coils of Q24 so that no parasitics are present in the output. The change is easy and will give you about 4 Watts out. ■

The History of Ham Radio

—part IX

Reprinted from QCC News, a publication of the Chicago Area Chapter of the QCWA.

In the early 1920s, in order to be truly portable a radio receiver had to be fairly light in weight, have a degree of efficiency, and be designed so that it could be moved about with ease. It was dependent, above all, on some type of portable antenna. *Reliable operation and portability were the basic criteria.* The antenna was of the loop type, of modest dimensions, and foldable. Dry "A" cells were the only source of sufficient current required for the filaments of the vacuum tubes. The plate supply depended on "B" batteries. The batteries contributed the major weight. The older UV 200 and UV 201 tubes were replaced by UV 199 and the WD11 tubes which did not require as much filament current, thus lengthening the operating life.

Using a loop for reception posed somewhat of a problem. The loops used had distinct directional characteristics. A loop had variation coverage as much as five to one forward compared to the sides. During the summer months, general activity among radio amateurs was not only down, but rather drab and unenthusiastic. QRN and static prevailed with regularity, and activity was carried on the assigned wavelength of 200 meters (plus or minus).

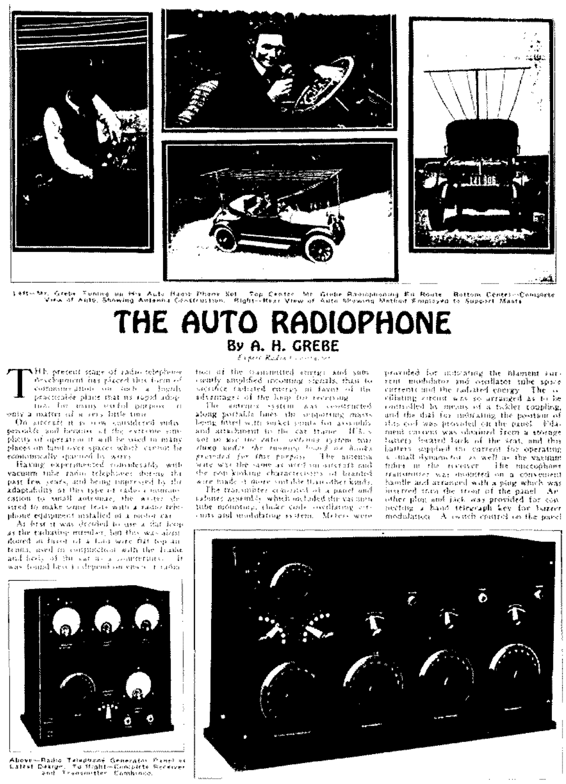

Fig. 1.

Fig. 2.

The broadcast listeners had the evening hours with little or no amateur QRM to contend with. The agreed upon hours of silence were regularly observed by the amateurs. Summer activity was usually looked upon as putting a damper on most ham transmitting. It was a time to take inventory of equipment, to rebuild and update for the coming winter season.

Whenever radio amateurs were involved in a project, ingenuity prevailed. A. H. Grebe, the well-known inventor and manufacturer of the CR line of receivers known and used by most amateurs during the twenties, went portable in a big way by giving the loop advocates an eyeful. He preferred to stay with the usual design—flat top, multiwire model—in spite of the limited cruising mobility (Fig. 2).

The aerial with auto-body-counterpoise configuration was preferred over a loop to avoid specific directivity. When ready to dismantle the outfit, what did Mr. Grebe devise? The entire overhead system was slung under the running board (cars had large running boards in them days) on hooks provided for that purpose. Instead of using dry cells, a storage battery was available for the heavy drain required for the tubes.

Fig. 3 illustrates what was available for radio entertainment while visiting the famous boardwalk at Asbury Park, NJ: the Roller Chair Special. The apparatus consisted of a radio chair so compact that three persons could sit comfortably side by side in the seat. A loop of the flat type was connected to the detector-amplifier held in the laps of the travelers. No coils were used, all tuning being accomplished solely with the variable condenser. Signals from stations over 200 miles distant were heard. Such sets were effective for wavelengths of 300 to 500 meters, and good results were often had at wavelengths up to 800 meters.

A more practical and somewhat more compact, all-around enclosed model of portability consisted of a receiver using a popular circuit known as a Grimes "Inverse Duplex" (Figs. 4, 5), having four tubes of the WD11 type. The set had a wavelength tuning capability of 200 to 3500 meters. The particular instrument shown in Fig. 4 was transported to the Philippine Islands in 1924 and served a lumbermill owner for years. It traveled by motorboat and other sundry conveyances over the broad island and mainland areas, giving the owner contact capability with his home base. The receiver was used in connection with a kW spark transmitter.

Legislation Problems Unsolved

The very rapid expansion of radio broadcasting during 1922/1923, together with the great demand for receivers and the need for some semblance of interference control, pressured legislators in Congress to come up with an urgent solution. The folks back home demanded action.

As a result of the first radio conference, held in Washington in the spring of 1922, Congressman White of Maine introduced a bill, known as the White Bill, HR 11964. For almost a year thereafter the bill was periodically under discussion, often under review, but constantly in the minds of the radio amateur.

On January 2, 1923, almost a year after the White Bill was introduced, the ARRL President, Hiram Percy Maxim, went to Washington for a hearing on the bill. He was instrumental in bringing to bear on the legislation the opinions and recommendations of the amateur fraternity. It was the ARRL up in front, promoting action and showing great interest in bringing about an equitable solution to the problems confronting listeners, the broadcasters, the commercial operators, and the thousands of amateurs. But speaking in behalf of radio amateurs in particular, it was Mr. Maxim's foremost objective to ensure that amateur radio would continue to have its rightful place.

The White Bill contemplated legislation to broaden the wave band for broadcasting so that the service could grow, expand, and perform in an orderly fashion, an action that was required so that Secretary of Commerce Hoover could be given authority to properly regulate radio in the United States. The bill was carefully analyzed, several recommendations and amendments were proposed, and suggestions were offered in an attempt to bring the listener and the radio amateur into accord. It was hoped that commercial interests would not be the dominating influence in this free and open domain, the ether.

However, in the End, What Happened?

The White Bill, HR 11964, passed the House on January 31, 1923, went to the Senate, and there was referred to the Committee on Interstate Commerce. Because of considerable outside opposition to various provisions, the bill languished and finally remained to die with the expiration of the 67th Congress on March 4, 1923.

Sensing trouble, and knowing the general attitude taken by many interests in the bill, White introduced a new bill on January 11th, with certain modifications proposed. It included provisions somewhat more palatable to the

Fig. 3.

objectors. The new bill was introduced as the White-Kellogg Bill. It also died in the face of considerable opposition. This virtually ended the hopes of all concerned to patch up the old 1912 radio law and bring order out of a simmering and ongoing chaotic situation.

On March 20, 1923, Secretary Hoover called his Radio Telephone Conference members to review the situation, hoping that a solution could be found to administratively cope with a defiant muddle. It was paramount that a way be found to open up more wavelength channels for broadcasting. The second National Radio Conference thus came to order.

In the meantime, amateurs, again caught in the middle but constantly cooperative, commanding the staunch support of the Secretary, had devised a so-called "Rochester Plan." The plan specified that in communities where QRM would be considerable and above normal in volume, quiet hours would be observed between 7 and 10:30 in the evening in all zones throughout the country, especially in the more heavily populated areas. At the conclusion of this second conference and after months of deliberation, a schedule evolved and was recommended. (See Table 1.)

Amateur Activities on the Rise

Amateurs were beginning to discover, through their constant experimenting, that wavelengths below 200 meters had possibilities not to be denied. The vacuum tube and the associated circuitry developed led the experimentally-minded amateur into unexplored fields. He discovered that by using vacuum tubes instead of spark gaps he was able consistently to span distances with ease and much less power on his assigned wavelengths Dropping down below 200 meters had tremendous possibilities. All of the early tests engaged in between individuals in various parts of the country were usually planned in advance and followed a schedule. Practically no one was listening below 200 meters. Nobody had a receiver at this stage of radio progress, nor the capability, to tune down much below 200 meters. With no signals on the air except by prearrangements between individual operators, there was only static to be heard. The ether was just an empty void below 200 meters and was generally avoided.

As the amateur slowly ventured into the lower unexplored regions, he faced one common question, namely, "Will the efficiency of the tubes I have available decrease as the wavelengths become shorter?" He knew that the larger tubes were still quite inefficient in design and the circuitry lacking in development. Many amateurs could not be convinced that "below 200 meters" was a fertile field in which to risk expensive "bottles." This area also was unsuited to the tuners used, and besides . . . the antenna he was using was too long, and nobody could be heard with whom to communicate. The League at Hartford had a great deal of convincing to do and a great many illusive misgivings to overcome among

Fig. 4.

Fig. 5.

the majority of hams. Most amateurs were unwilling to let down their old multi-element aerials, disconnect the ammeter from the antenna lead, or trust the plain Hartley transmitter circuit. There was still an amount of extraordinary experimenting ahead.

Wavelength Vs. Frequency

Another major stumbling block in the way of progress was evident. This was the fact that nobody knew or was seriously concerned about how to make wavelength measurements. Up to this time, very little reference had been made to the term *frequency*, nor much attention paid to conversion from wavelength to frequency. Conversation among radio men held rather tenuously to *meters*. Not until the League convinced the radio division of the Bureau of Standards that by transmitting measured frequencies over their Washington station, WWV, for amateurs to copy and adjust circuits to conform to, would the ice be broken. So, from this time on, the wavemeter gradually became the most important laboratory instrument in the ham shack. Schedules were now arranged to have transmissions from WWV appear periodically, set for eleven pm, EST, on specified wavelengths and frequencies. They provided calibration settings for all home-built wavemeters, permitting the receiving tuners to be modified or rebuilt or redesigned for receiving the higher frequencies. A new and important era in amateur radio was now set in motion with vigor. ■

Below 130 meters	Available for special licensing.
130 meters	Government, CW, exclusive.
130-143 meters	Available for special licensing.
143 meters	Government, CW, exclusive.
143-150 meters	Available for special licensing.
150-200 meters	Amateur, CW, ICA, phone, spark, exclusive.
200-222 meters	Special amateur, technical & training schools, CW, exclusive.
222-231 meters	Aircraft, CW, ICW, phone, nonexclusive.

800 meters	Radio compass, CW, ICW, spark, exclusive.

Table 1. Schedule evolved from the 2nd National Radio Conference. Class A and B broadcasting stations were assigned a wave band of 10,000 cycles, none closer together than 20 kilocycles in frequency. Within each area zone there would be ten stations separated by 50 kilocycles.

Add-On Keyboard for Your Keyer

—the "a la carte" design

Easier than you think.

Edward J. Faber K4BZD
554 Sulgrave Drive
Columbia SC 29210

If you have an electronic keyer in your shack, you can go the complete keyboard route more easily than you think. This project is recommended to all who have home brewed or constructed an electronic keyer. However, even if it is your first time for an IC project, you should have little trouble. The cost of this project can be negligible if you can find an old keyboard and a handful of diodes. Only three ICs are required to get you started.

Your existing keyer is used as a functional part of the Morse keyboard . . . a la carte (you can make one your way without a lot of fuss). Your keyer should be of a semiconductor design, preferably containing a +5-volt supply. If your keyer uses 12AT7s, please read on; it may still be easy to get rid of the bug! Chances are your keyer already has many of the circuits required to make the a la carte design work. If your keyer has any of the below listed features or functions, that part of your Morse keyboard is ready to operate.

- Power supply with off/on switch
- Timing and weight circuits for dot/dash elements
- Monitor, volume, and possible tone controls
- Transmitter keying circuits
- Operator test-tune controls
- ROM or PROM message readout options

To build this additional hardware would cost you a buck-two-eighty, so why bother to do it again?! The nice thing about the a la carte design is that your keyer remains usable at any instant you desire to cease sending via the keyboard. In most cases, no modification or changes are required within your keyer, although getting into it may be desirable to achieve the simplest interface to the keyboard circuits.

So what does it take to order up one a la carte keyboard? Take a look at the menu in the parts list. Items 1 through 5 you'll need for the main course. Item 6 is the dessert and, therefore, optional, depending upon your application and keyboard design.

How to Get Rid of the Bug

In this design, I used a diode matrix to establish the Morse coding elements (dots and dashes—forget about the spaces; your keyer takes care of that). In Fig. 1, the diodes forming the dot elements connect to a "dot" 8-bit shift register (U2), and the dash diodes connect to the "dash" shift register (U1). Examples of the diode arrangement to form the letters Q, S, and T are provided. The diodes may be wired all on one assembly to simplify wiring. The 8-bit shift registers store the "dot" and "dash" characterization for each letter in the order sent. There is no requirement to characterize the elemental spaces because this function resides in the logic of your keyer.

When a keyboard switch is depressed, a logic zero (≈ 0V) appears on the output (pin 9) of U1 or U2. If the character being sent begins with a dash, pin 9 of U1 goes low. If the character begins with a dot, pin 9 of U2 goes low. The transition from a high to a low causes one of the terminals on your keyer to see a ground; thus it (the keyer) begins to do its thing, and it sends a beautiful dot or dash.

If the shift registers were not clocked, a second dash or dot would follow the first just as if you were holding down the key on your keyer. If both of the shift register outputs are high, the keyer again does its thing by doing nothing. When your keyer is idle, the a la carte keyboard assumes you have completed sending a letter, and it awaits the suggestion that you desire to send another letter. The letter-space oscillator (U3) controls this timing (Fig. 2). It sends a pulse (C) to the

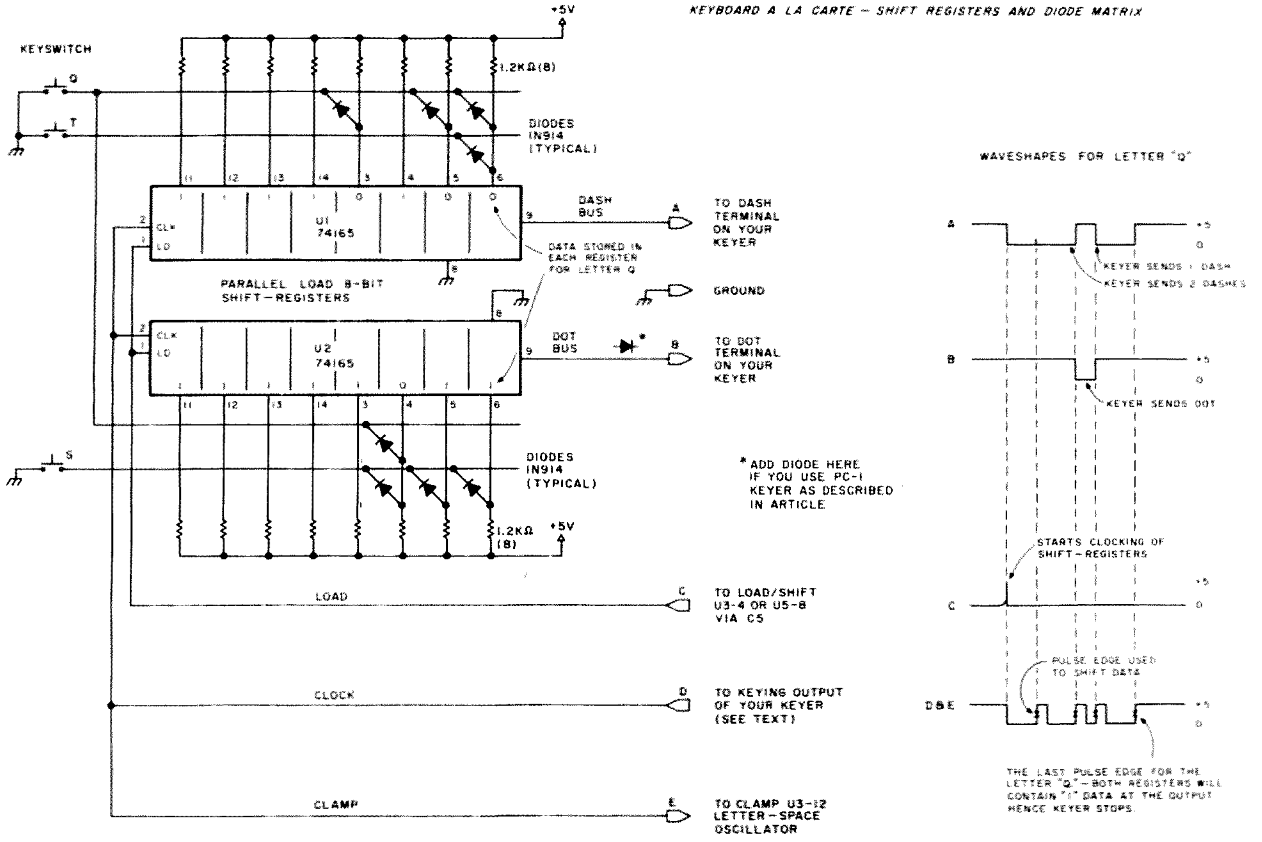

Fig. 1. Keyboard a la carte—shift registers and diode matrix.

shift register's load/shift input (pin 1) so that you can load in the next character from the diode matrix. If this pulse arrives at the shift registers when a key is being depressed, the next dot or dash instantly is on its way to the proper input of your keyer. Fig. 1 shows logically how the letter "Q" is loaded into the registers.

When your keyer is sending the letter, an output signal similar to the waveshape shown in Fig. 1 (D and E) is routed to the shift registers (pin 2). This is a true representation of the Morse code as sent to your transmitter. It serves as a clock to advance the data stored in each of the eight locations in the shift registers. The 74165 clocks on the positive-going pulse at the end of each dot or dash element formed in your keyer. With the generation of the letter "Q", the data is shifted four times after the initial start by the letter-space oscillator. The clock signal must be of the phase shown in the diagram or your keyer will send extraneous signals. In my keyer, a signal was acquired at the base of one of the transmitter keying transistors and routed through a 7400 logic gate to invert the signal to the desired phase. Check around your keyer; you'll find an appropriate loaction. The signal should measure about +5 volts when off, and near 0 volts when a dot or dash is present. There are all kinds of ways to capture this output. You can even use one of your transmitter keying outputs with an appropriate interface to give you the proper clocking signal. Here's your chance to apply some of your own talents to the design.

The Main Menu

If you just connect U1, U2, and U3, the diode matrix, and the keyswitches, as shown in the diagrams, you will have a very versatile system. The variable resistor network provides a full range of adjustments to control the speed or timing of the letter-space oscillator. R2 and perhaps R5 should be mounted as operating controls. The other variables may be fixed or trimmed one time to achieve the adjustment ranges desired. With these controls and those on your keyer, you can establish a keyboard fist of your very own style.

My keyboard performed with spectacular success. Speed was controllable from 4 to 50 wpm. The shift registers provided one full letter of memory. No problems with keybounce, transmitter RFI, EMI, or other intermittent operation occurred. Besides all the letters and numbers, the shift registers can store up to eight code elements, so you can send $\overline{AR}$, $\overline{AS}$, $\overline{BT}$, $\overline{SK}$, ?, /, $\overline{CQ}$, error, and any other procedural signals you can invent. However, remember that the registers will not store space data.

Several additional features were added to my keyboard to aid in the operating pleasures of the device. One is a "test" switch to effectively short the "V" keyswitch to ground. This permits the continuous execution of "Vs" for adjustment purposes. An LED was also added on the control panel to give a visual indication that the keyboard is active and ready to load the next character. Timing this light when sending Vs will give a good indication of sending speed on the keyboard. The LED is connected at U3, pin 6 in the simple version and at U5, pin 8 in the optional space-bar version.

The keyboard should work with just about any keyer. You can test the en-

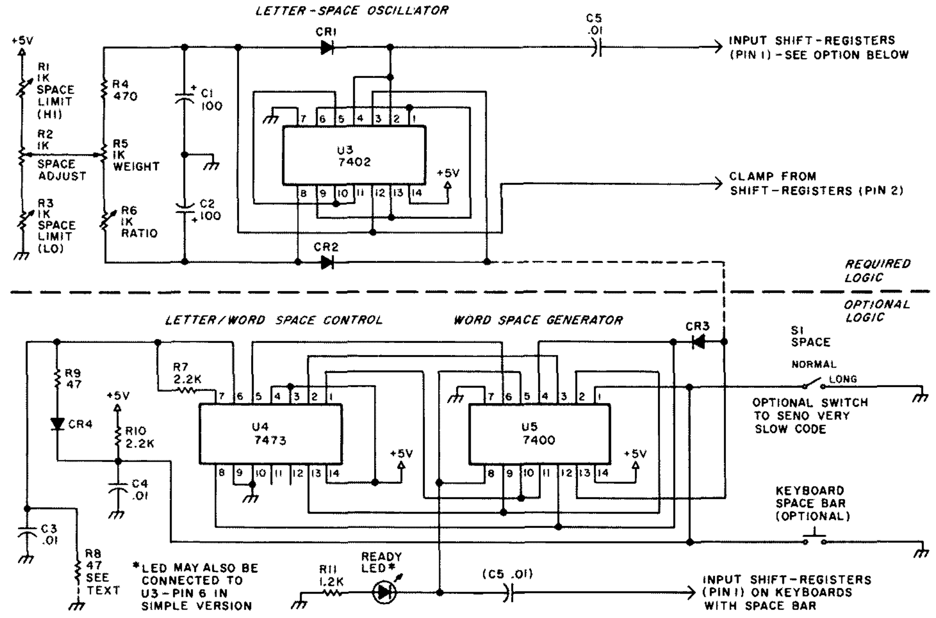

Fig. 2. Keyboard letter/word space-timing circuits.

tire concept on your keyer with a couple of push-button switches before you invest in a keyboard. This approach is recommended in your prototype design. Regardless, I see no complication in going keyboard a la carte with popular keyer designs such as the Accukeyer and the more recent micro-to-keyer concepts. The only test equipment used during many hours of experimenting was a multimeter and several LEDs. No ICs or other parts failed for any reason whatsoever.

Here's the Dessert

If the keyboard you have selected to use contains a space bar, you can add an optional circuit, shown in Fig. 2. It consists of a 7400 gate and a 7473 flip-flop. For most parts, it is a reproduction of the Data Signal, Inc., keyer (described at the end of this article) less the monitor circuits and transmitter keying transistors. It is shown here with permission of Data Signal, Inc.

The circuit sends controlled letter-space and word-space pulses which activate the shift registers at the start of the next letter or next word being keyed from the keyboard switches. When R8 is grounded (this is a dot input for the circuit when it is used as a keyer), the space oscillator, U3, starts to run. This sets U4. Also, when U3 starts its cycle, a 1 is placed on U5, pin 8, and a positive pulse is sent to the shift registers to permit loading of data from the diode matrix. Once this occurs, the oscillator and flip-flop must complete the cycle before a second pulse can be sent to the shift registers. Thus, the "letter" space timing is generated. When the space bar on the keyboard is depressed, R10 is grounded (the dash input to the keyer circuit) and flip-flop U4 extends the rest period to the full word-space timing as determined by the variable adjustments at the oscillator. A convenient letter/word spacing switch fixes the spacing at its maximum set length. The addition of this switch is useful if the keyboard is to be operated at very low speeds for teaching purposes or when operating on the Novice band.

The Author's Keyer

For my design, I used a Data Signal, Inc., PC-1 keyer. It was constructed from a kit which cost about $16.00. The kit consisted of four ICs, transistors, diodes, pots, capacitors, speaker, PC board, and wire. The keyer was mounted in a small utility box with a simple power supply. The entire kit could be incorporated into the keyboard package without difficulty. The circuit shown in Fig. 2 is the basic keyer (you could buy two and use one for the keyer and one for the space-word timing circuit). The design of the PC-1 keyer was such that I was required to insert a diode in the dot input terminal (Fig. 1) to eliminate a low-impedance path to the dash bus.

I am grateful to Data Signal for permission to use this part of their keyer design in the a la carte keyboard. Those interested in further information should correspond directly with the company. I have no relationship, responsibility, or interests in the business activities of Data Signal, Inc. Their address is 2403 Commerce Lane, Albany, Georgia 31707, (912)-883-4703.

Construction Hints

Construction of the a la carte design will be dependent upon the keyboard you are able to use. Remember, you may use push-button switches to fabricate a keyboard design if the cost of a purchased unit is out of the question. Regardless, switch contacts should be normally open if you follow these schematics. The diode matrix can be mounted on a block of wood about one-half an inch thick by 3½ to 4 inches wide and 7 or 8 inches long. In my keyboard, the block was sized to fit under the keyswitches. The diodes are inserted into predrilled holes in the board such that the body of the diode is hidden from view and the diode leads extend out through each side of the board. The proper polarity of the diode must be observed when inserted (see Fig. 3). Also, remember that pin 6 of U2 and U3 is the first-in, first-out data line for each chip. Reversing the order of the data lines will result in operational failure.

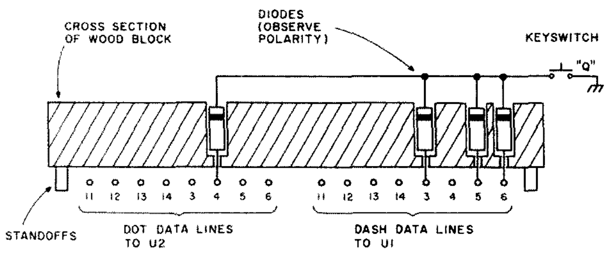

Fig. 3. Diode matrix assembly (wiring for the letter "Q" shown).

Parts List

Item	Qty.	Description	Approx. Cost
1.	1	Keyer, yours—if you don't have one, see text	---
2.	1	Keyboard (45 or more keys, microswitches will work)	don't pay over $19
3.	2	Dot/dash shift register ICs (74165)	$1.25
4.	1	Dot/dash matrix, you'll need about 200 signal diodes	$4.00
5.	1	Letter/space oscillator—7402 IC, plus misc. parts	$3.00
6.	1	Word/space generator—7400 and 7473 ICs	$1.00

The matrix board also contains the sixteen pull-up resistors. They are connected to the sixteen data lines at one end of the board. The other resistor leads are all common to the +5-volt source. A layout for the diode matrix should be started by preparing a template on graph paper. Mark the hole pattern for each diode so that they can be connected between each of the 16 data lines according to the code elements of each character. Locate the holes for the pull-up resistors at one end of the board. Wrap a piece of tape around the bit you intend to use to drill out the diode holes so that the bit will stop before going all the way through the board. Another piece of tape should be wrapped around a needle or bit of the appropriate size of the wire leads of the diodes. Use the needle to extend the hole for the diode leads to pass completely through. In this case, the tape helps to center the needle in the existing diode hole.

Small crimp-on contacts of an unknown variety were used to provide a mating interface between the wires of the matrix and the wiring coming from the keyswitches and logic. The leads, however, could be soldered if consideration in the layout is made for disassembly and repair. The matrix board was mounted on four standoffs, as shown in the diagram, to insulate it from the keyboard housing.

The ICs can be mounted on just about any old vectorboard. I used sockets, but they were not necessary. Figs. 1 and 2 are arranged to show a wiring configuration for the ICs. The true schematic representation is not shown in detail to make the drawings more useful in the assembly of the project. Refer to appropriate data books for schematic details. The control panel design, again, is a function of the keyboard used, and the control options selected from the text.

Bypassing and filtering of the power source is desirable at several places to ensure reliable performance. Recommendations here are a function of the power source used and the effectiveness of the ground system and, therefore, are left to the builder to determine. In the cabling between the keyboard and your keyer, use shielded wire if possible. These lines should be kept as short as possible. The use of connectors and plugs might be more appropriate than terminal strips to help prevent false triggering from rf in the radio shack.

One final warning about the operating effects of your new keyboard . . . Your SSB friends will wonder what happened to you. You'll be a born-again CW man, this time without the bug. ■

Little Extras for the Century 21

— easy add-ons

Make a good rig a little better.

Bob Borum KN4JJG
5708 Orient Rd.
Tampa FL 33610

Recently, I bought a Ten-Tec Century 21 80-10 meter CW-only transceiver. I used it for a couple of weeks just as it came from the box, and all in all I was very happy with the ease of operation and the fine signal reports I was receiving. But, being the typical ham, I thought I would change things a bit.

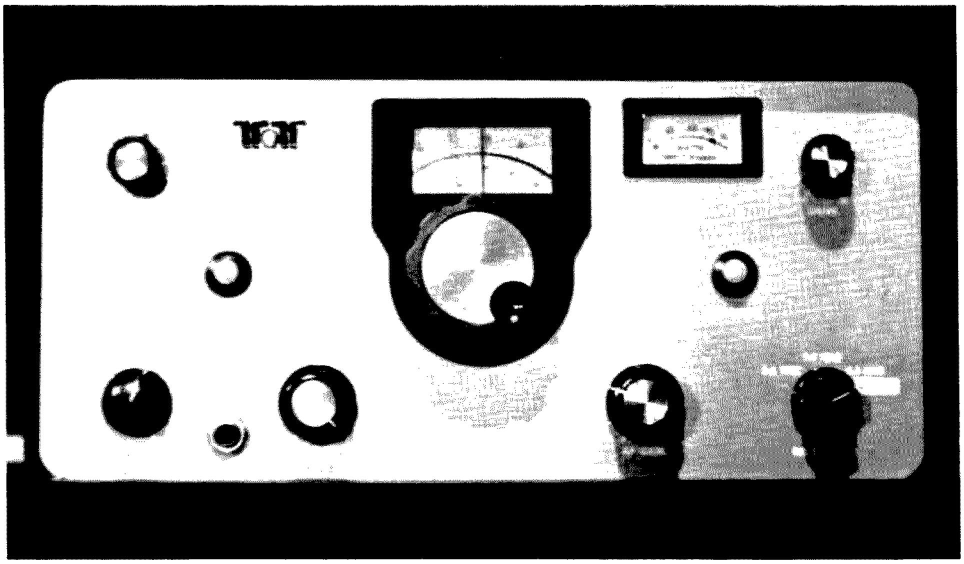
Little Things

The first things that bothered me were the prop-up feet and the size of the control knobs. If you have small fingers the knobs are okay, but they got lost in my big fingers. Digging through my junk box, I came up with a matched pair of knobs for the band-change and selectivity switches, and another pair for the rf and af controls. The ease of operation greatly increased. As for the feet, I had a couple of 1¼-inch feet left over from another project.

Bigger Things

Everything was all right for about a week, and then the sidetone began to get to me. It sounded like a frog was living in the radio. The note was about 350 Hz and my ear is tuned to around 700 Hz, so out came the schematic and off came the bottom cover. R1, a 68k ½-W resistor (47k in my unit) on board the 80356, controls the frequency of the sidetone. If this resistor is decreased in value, the tone increases in frequency. I paralleled another 47k resistor with R1 and the tone was just about right. So I removed R1 and installed a wire to one of the solder pads and a 22k ½-W resistor to the other. I found a space on the rear panel to mount a 25k linear pot in series with the wire from the other solder pad. Now I have variable sidetone.

As long as I had the board out and the bottom off, I looked around for solder whiskers, cold solder joints, etc. I noticed that the selectivity switch had several unused connections, and, sure enough, the selectivity switch had other positions available by turning the switch to the left from the 2.5 position. This made me think that if 500-Hz selectivity is good, wouldn't 200-Hz be better? The present active filter circuit in the Century is a good one, so I just dupli-



The new, larger knobs installed, with the selectivity switch in the .2-kHz position.

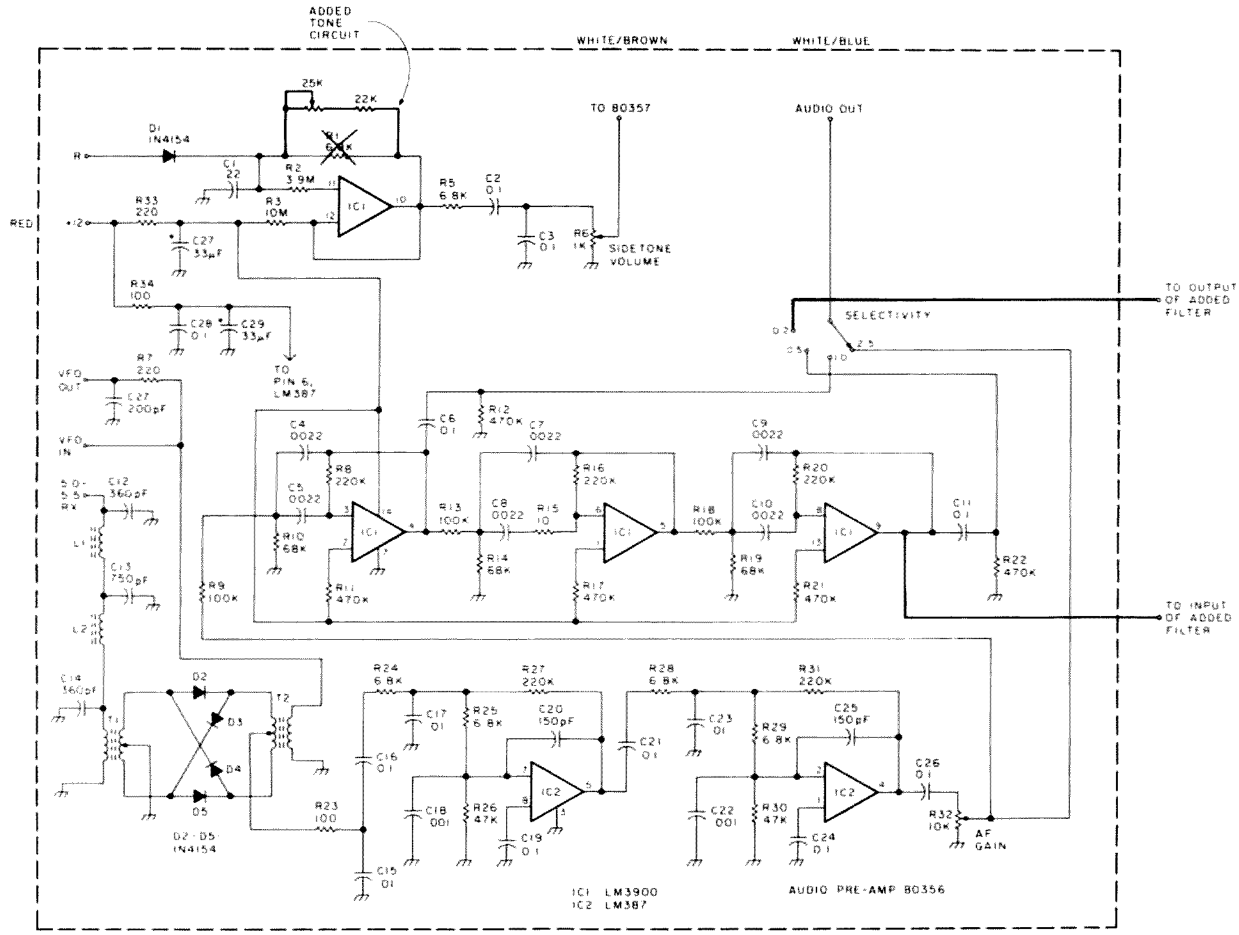


Fig. 1. 80356 audio preamp.

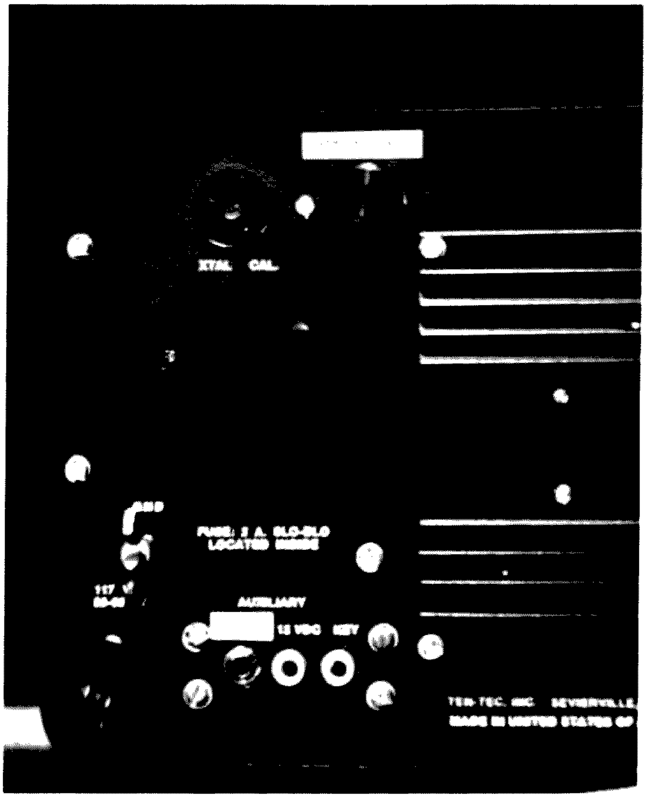
Bottom view of placement of auxiliary speaker jack.



Mounting of the sidetone control and the auxiliary speaker jack.

cated it by using all 4 of the amps in the LM3900 chip. Construction is straightforward, using a small square of vectorboard. I used a wire-wrap 14-pin IC socket, and it really simplified construction. With Super Glue™, I mounted 2 fiber standoffs to the 80356 board to mount the new active filter on after construction. I Super Glued the vectorboard to these standoffs.

The selectivity knob is the setscrew type, so by moving the connections on the board the knob can be rotated so the dial still reads correctly. A small Dymo™ label slightly to the right and down a bit from the .5 position is the .2 position. This modification is very simple, works well, and can be removed to have the circuit made normal, with no indications that it was ever done. Now, talk about single signal selectivity! The signals just leap out at you when the tone of the signal is tuned to 750 Hz.

Last but not least, I installed an external speaker jack on the back in place of one of the 12-V accessory phono jacks. I used a miniature phone jack of the shunting type. If an external speaker is plugged in, the internal speaker is cut off. Care should be taken so that the other 12-V accessory jack is not shorted to the phone jack you install. I will be glad to answer any letters concerned with these modifications if there is an SASE enclosed. Let's see . . . amplified agc would be nice, maybe a vernier control for the offset tuning, and SSB shouldn't be too hard. Well, that will come later; I'll enjoy what I have for awhile.

All parts for these modifications can be bought at Radio Shack for around $15.00.■

The Many-Talented 723

—how can regulated supplies get much simpler?

Design your own voltage regulator.

Whenever you need a regulated power supply for the test bench or for that special IC project you're working on, consider the 723 integrated voltage regulator. This handy little device is inexpensive (priced around 70¢), simple to use, and offers a lot of capability in a small package. With it, you can build a quality regulated power supply using very few parts. Read on and I'll show you how easy it is to custom design your own regulator around the 723 to suit your particular application.

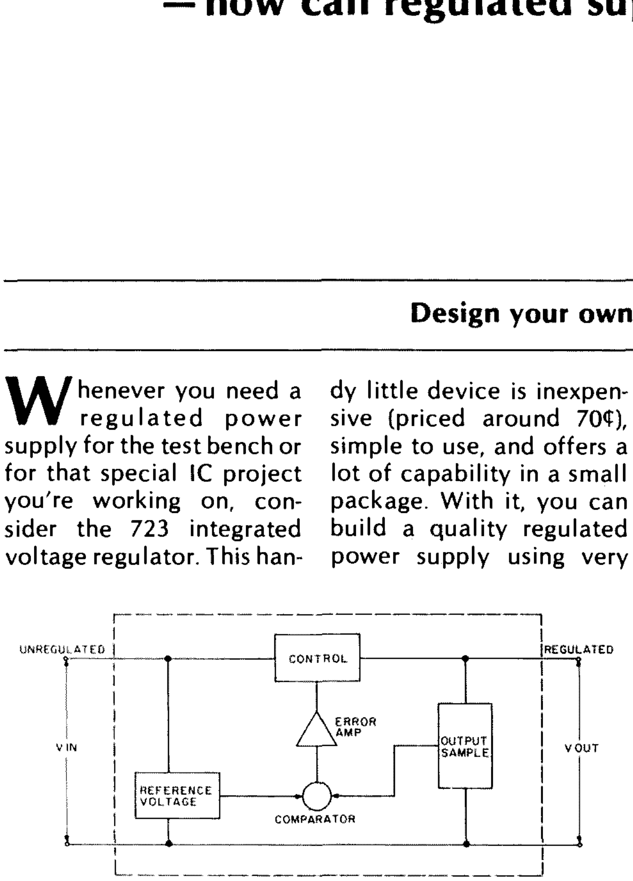

Fig. 1. Functional block diagram of a series voltage regulator.

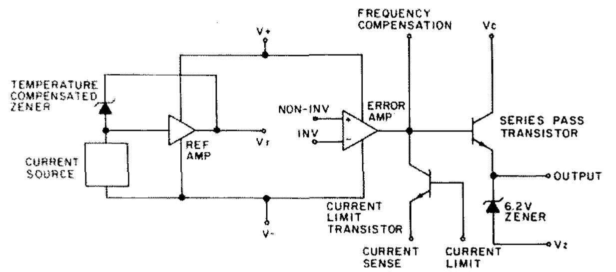

Fig. 2. Internal 723 functional block diagram.

Before we begin, let's look at a few characteristics of the device itself. The 723 operates with a rectified and filtered input voltage in the range of 9.5 volts to 40 volts. The output voltage is adjustable from 2 volts to 37 volts with .01% line and load regulation.

In case the terms "line regulation" and "load regulation" are unfamiliar to you, line regulation is the percentage change in the regulator output voltage for a change in the input voltage; load regulation is the percentage change in the regulator output voltage for a change in the regulator output current. Ripple regulation, which is defined as the ratio of the peak-to-peak input-ripple voltage to the peak-to-peak output-ripple voltage, is typically 45 dB.

As you can see, the regulation characteristics of the 723 are excellent. Note, however, that the 723 has two disadvantages that we must deal with. The first of these is that this IC can provide a maximum output current of only 150 mA. This limitation can be overcome by adding a single external pass transistor, as we will see later. The second disadvantage pertains to the value of the internal reference voltage of the 723, but I'll discuss this later and show you how to overcome it as well.

To illustrate how easy this device is to use, let's look at the 723 internal structure and then design a few regulator circuits with it. Fig. 1 shows the essential functions of a typical series voltage regulator. The reference voltage element provides a known stable voltage which is

compared with a sample of the regulated output voltage at the comparator. The comparator subtracts the sampled output voltage from the reference voltage. This difference voltage (or error voltage) is then amplified by the error amplifier to provide drive for the control element. The control element behaves similarly to a valve in a water line in that it conducts more or less to adjust its resistance, and hence its voltage drop, to yield the proper output voltage across the load.

Now compare the internal features of the 723 (Fig. 2) with the regulator block diagram (Fig. 1). The 723 contains all the necessary regulator components except the output sampling element. The reference amplifier, current source, and zener diode comprise a stable temperature-compensated voltage source. Other internal functions include an error amplifier, a series pass transistor (the control element), an adjustable current limiter, and a 6.2-volt zener diode. The input of the error amplifier functions as a comparator by taking the difference between the voltages applied to the inverting and noninverting inputs. Note that the current limiter and the 6.2-volt zener diode are features that are not essential to the operation of the regulator. However, the current limiter is extremely useful for setting the maximum (short circuit) current output from the regulator, and the 6.2-volt zener diode can be used in floating or negative voltage regulator applications. One caution should be noted here—the 6.2-volt zener diode is only accessible in the 14-pin dual-in-line package. The flat pack and the 10-lead metal can packages do not have enough pins to accommodate all the internal functions of the 723, so the Vz output is not accessible. The pin outputs for the various packages are shown in Fig. 3.

High-Voltage Regulator (7.1 volts to 37 volts)

A typical 723 regulator circuit is shown in Fig. 4. In this figure, the temperature-compensated zener, the reference amplifier, and the current source are represented by an equivalent independent voltage source (a battery) to simplify the diagram. Vr may vary somewhat from device to device (6.6 volts to 7.5 volts), although it is typically 7.1 volts. The value of Vr establishes the lowest possible output voltage obtained from this circuit.

R1 and R2 form a voltage divider network from which the output sample (Vx) is taken. Therefore $Vx = VoR1/(R1 + R2)$. If Vx is greater than Vr, the error voltage (which is $Vr - Vx$) will be negative and the output of the error amplifier will decrease, causing the series pass transistor to conduct less. This, in turn, causes Vo to decrease until Vx is equal to Vr. At this point, the error voltage is essentially zero and the output voltage (Vo) remains steady at a value equal to $Vr(R1 + R2)/R1$. Should the output voltage begin to decrease, Vx will begin to decrease proportionally. As Vx attempts to drop lower than Vr, the error voltage becomes positive, causing the output of the error amplifier to increase. The pass transistor then conducts harder, which causes Vo to increase until $Vx = Vr$ once again. As before, $Vo = Vr(R1 + R2)/R1$.

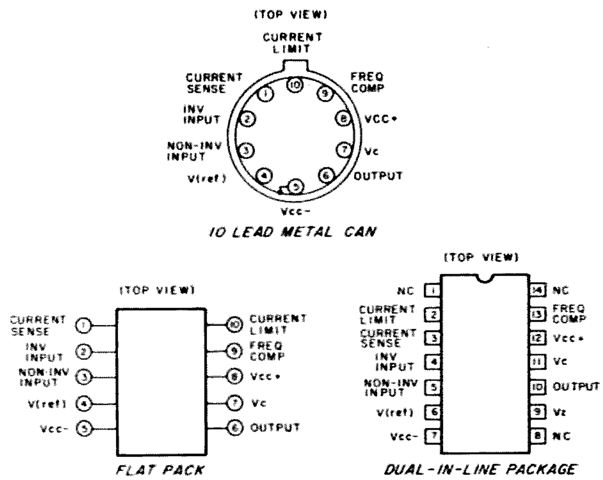

Fig. 3. 723 IC pin outputs.

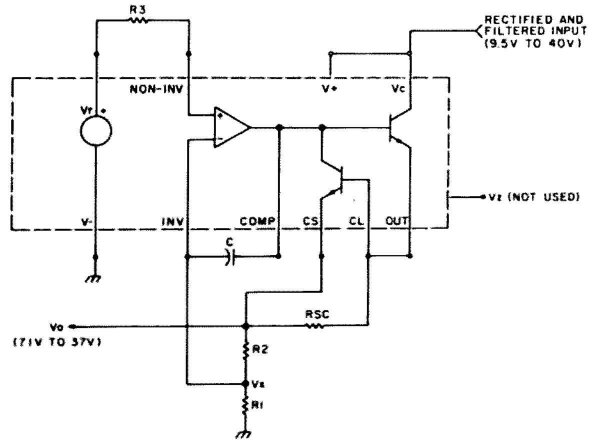

Fig. 4. High-voltage regulator (7.1 V to 37 V). To select component values:
1. *Choose Vo*
2. *Measure Vr (or assume $Vr = 7.1$ V)*
3. *$R1 = Vr/Ib$ (Ib is between 0.1 mA and 5 mA)*
4. *$R2 = (Vo - Vr)/Ib$*
5. *$R3 = R1R2(R1 + R2)$*
6. *$Rsc = 0.65$ (Isc = max. output current limit)*
7. *C = 100 pF to 500 pF*

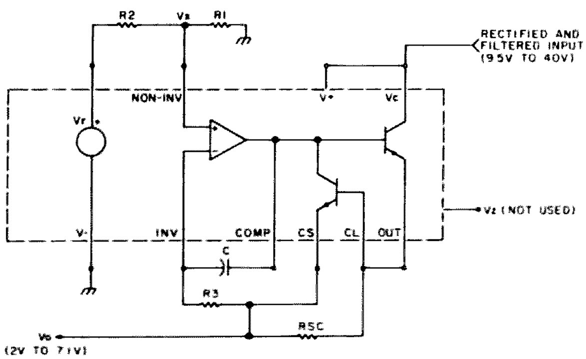

Fig. 5. Low-voltage regulator (2 V to 7.1 V). To select component values:
1. *Choose Vo*
2. *Measure Vr (or assume $Vr = 7.1$ V)*
3. *$R1 = Vr/Ib$ (Ib is between 0.1 mA and 5 mA)*
4. *$R2 = R1(Vr - Vo)/Vo$*
5. *$R3 = R1R2/(R1 + R2)$*
6. *$Rsc = 0.65/Isc$ (Isc = max. output current limit)*
7. *C = 100 pF to 500 pF*

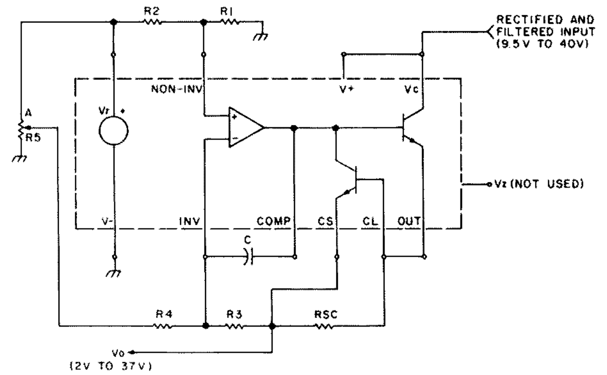

Fig. 6. Variable voltage regulator (2 V to 27 V). To select component values:

1. *Choose Vo (here, Vo is the max. output voltage)*
2. *Measure Vr (or assume Vr = 7.1 V)*
3. *R5 = Vr/Ib (Ib is between 0.1 mA and 5 mA)*
4. *R1 = VrVo/Ib (Vr + Vo) (Ib is between 0.1 mA and 5 mA)*
5. *R2 = R1(Vr/Vo)*
6. *R1 = R3*
7. *R2 = R4*
8. *Rsc = 0.65/Isc (Isc = max. output current limit)*
9. *C = 100 pF to 500 pF*

Rsc is a series current-limiting resistor which is selected to limit the maximum current the load can draw (Isc). Since this resistor is connected between the base and emitter of the current-limiting transistor, the load current through Rsc forward biases this transistor. Note, however, that the current-limiting transistor does not conduct until its base-emitter junction potential is overcome (approx. 0.65 volts). For example, select Rsc = 0.65/0.10 = 6.5 Ohms. When the load attempts to draw more than 100-mA output current, the current limiter conducts and robs the series pass transistor of drive current from the error amplifier. The result is that the output voltage begins to drop off to restrict the current to the limit set by Rsc. Rsc is often selected so that the current capability of the regulator and power supply components is not exceeded. Therefore, you can short the output leads of the power supply without damaging the power supply or regulator.

Follow the steps in Fig. 4 in selecting components for this circuit. First, choose R1 so that the current drawn by the voltage-divider network (R1 and R2) is between 0.1 mA and 5 mA, and let's call this current Ib. Suppose we let Ib = 1 mA; then R1 = Vx/Ib. But note that we previously stated that regulator action tends to maintain Vx = Vr, so R1 = Vr/Ib = 7.1/.001 = 7100 Ohms. Next, the selection of R2 is dependent upon the output voltage you want; R2 = (Vo − Vr)/Ib. Finally, R3 is chosen to balance the impedances seen by the input of the error amp. This improves error amp stability and accuracy. Therefore, R3 should be equal to the parallel combination of R1 and R2. If you want to keep the parts count to an absolute minimum, then just connect Vr to the noninverting input of the error amp and leave R3 out altogether. In most applications, you'll never notice a difference. The capacitor (C) in most 723 regulator applications should be 100 pF to 500 pF. This capacitor prevents the error amplifier from oscillating.

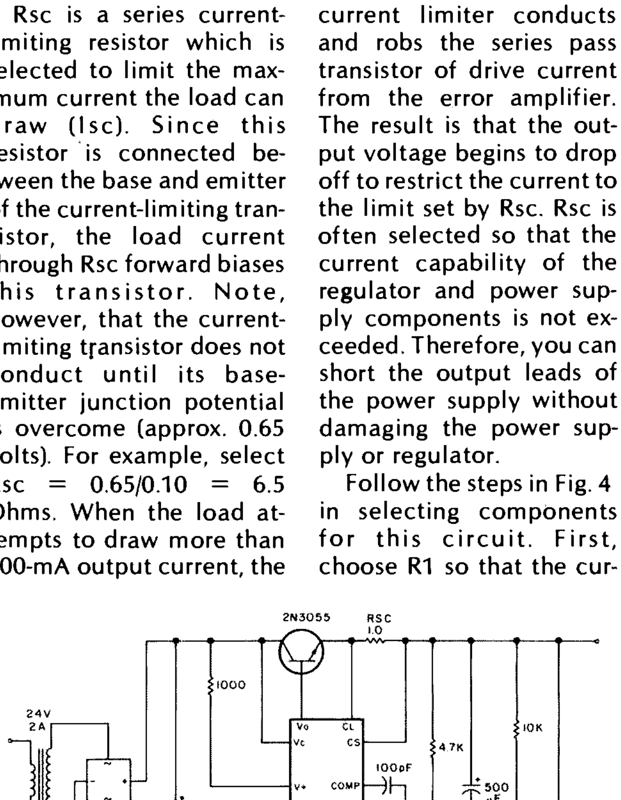

Fig. 7. Variable regulated power supply.

Low-Voltage Regulator (2 volts to 7.1 volts)

The circuit of Fig. 4 has one primary disadvantage in that the lowest output voltage obtainable from the regulator is limited by Vr. Therefore, this circuit cannot produce a regulated output voltage of less than 7.1 volts. If you need a 5-volt regulated output for TTL operation, you're out of luck. All is not lost, however, since we can get less than 7.1 volts out of the regulator by rearranging the components as shown in Fig. 5.

In this configuration, Vr is divided by R1 and R2 to obtain a lower reference voltage (Vx) for the error amplifier. The regulated output voltage is sampled via R3 at the inverting input of the error amplifier. Regulator action is similar to that previously described. In this case, the error amplifier adjusts the conduction of the pass transistor until Vo = Vx. First select R1 for a voltage divider bias current (Ib) of from 0.1 mA to 5 mA as before, (R1 = Vo/Ib). Rsc functions as previously described.

Variable-Voltage Regulator (2 volts to 37 volts)

The regulator circuits in Figs. 4 and 5 have fixed output voltages. Both of these regulators could be made variable by replacing R1 or R2 with a potentiometer, but we still have the disadvantages previously mentioned in that the output of the circuit in Fig. 4 is limited to an output voltage range of 7.1 volts to 37 volts, and the regulator of Fig. 5 is limited to an output voltage range of 2 volts to 7.1 volts. This is a particular disadvantage when working with differing logic families because TTL circuits require 5 volts, while transistor and MOS circuitry require higher voltages. Therefore, if you're building a variable power supply for your test bench, it is desirable for the supply to be variable over the entire range of the 723, if possible. The regulator configuration in Fig. 6 will do this quite nicely.

R1 and R2 form a voltage divider for the reference voltage (Vr), while R3, R4, and R5 form an adjustable network which samples both Vo and Vr. Together, these two networks comprise the input circuitry for the error amplifier. For good bias stability, let R1 = R3 and R2 = R4, so that, when the wiper of R5 is at point A, the voltage from the error amplifier, and hence Vo, is at a minimum (usually around 2 volts).

Now let's determine the

component values for this circuit. We can begin by choosing R5 so that the current drawn from Vr is less than 5 mA (Vr is normally capable of supplying 15 mA max.). Once R5 is determined, choose R1 + R2 so that this combination draws from 0.1 mA to 5 mA from Vr. Continue with the steps outlined in Fig. 6 to complete the circuit.

Since the internal series pass transistor is only capable of 150 mA, you may want to consider an external pass transistor. Almost any good NPN power transistor capable of dissipating sufficient power for your current requirements will be suitable. An external pass transistor can be employed in the circuits of Fig. 4, Fig. 5, or Fig. 6 by connecting it just as shown in Fig. 7. The internal pass transistor now becomes a driver for the external series pass transistor.

The circuit I use for various IC projects is shown in Fig. 7. The components for this circuit were chosen from the formulas given in Fig. 6. This regulated power supply provides a variable output of approximately 2 volts to 15 volts. Rsc was selected so that the maximum output current is approximately 1.2 Amps.

So there you have it! Now it's your turn, so give it a try. Just follow the steps given in each figure to build a regulated power supply to your own specifications. Since the selection of the bias current (Ib) is not critical, the component values selected can vary over a rather wide range so that you have plenty of flexibility in using parts you may already have on hand. ■

One-Chip Tone Decoding

—how simple can it get?

The MK5102N.

Mostek Corporation of Dallas, Texas, has produced the latest in microcomputer control of phone systems. The MK5102N integrated tone receiver chip became available in engineering prototype models in January, 1978, and will revolutionize the use of tones to control remote equipment and improve the interface of phone and radio systems. The chip accepts the high- and low-group tones from the standard DTMF (touchtone™) pads, and provides outputs of either a 4-bit binary code or a dual 2-bit row/column code.

I'll begin with a short introduction to the tone system. The phone companies introduced the 8 standard tones for dialing their touchtone™ phones in 1963. Previously, the dialing was performed by interrupting the 20 milliamps (mA) of direct current. The current was interrupted at 10 Hz with a switch on the dial as it spun back to its spring-loaded position. Dialing the number 5, for example, would give 5 pulses. This has the disadvantage of requiring excessive amounts of power (using enough voltage to drive the 20 mA through miles of phone line), and it introduced bothersome clicking into the phones of other users whose phones were connected through the same bundle of wires to the central switching exchange. The tone system was developed to help overcome these problems. The eight tones fall in the audio frequency spectrum from 697 Hz to 1633 Hz. They have been carefully chosen to not be harmonically related to one another, and are spaced approximately 10% apart. This spacing allows for some margin of error so that one tone is not mistaken for another.

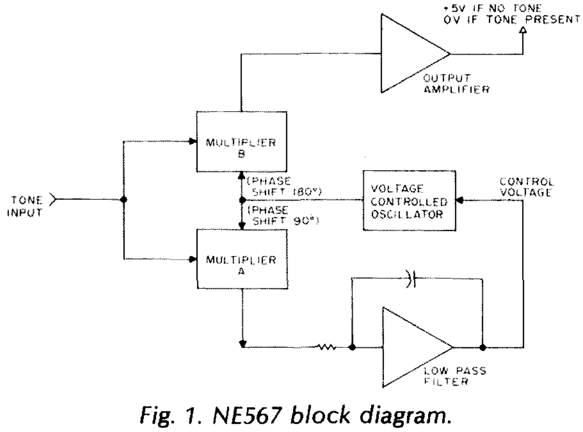

Fig. 1. NE567 block diagram.

The phone company requires that the tones be within 1.5% of their center frequency to be properly decoded. This requires that the tone transmitter be well controlled in all conditions of temperature, humidity, and power supply voltage. I'll bet that some of you have heard a tone generator fail in the cold winter weather because it failed to meet the ±1.5% tolerance. Another of the phone company's requirements is that the two tones can have no more than a two dB difference in amplitude. This means that the two voltage amplitudes must be in a ratio of less than 1.6 to 1. For example, if the low-group tone is 1.0 volts root mean squared (rms), the high-group tone must be less than 1.6 volts rms, but greater than .625 volts rms. The actual amplitudes of the signals are normally measured on a 600-Ohm impedance standard audio line, where 1 milliwatt (mW) of power across the line is designated 0 dBm. The specification for tones on the phone lines is that the nominal levels be −4 to −6 dBm, with the low-group minimum of −10 dBm, and a high-group minimum of −8 dBm. The maximum level of the two combined tones is +2 dBm. These levels will not be important for the decoder chip, but will enter into the discussion when we regenerate

the tones to be placed on the phone line. Also, the phone company specifies that the tones should have a minimum duration of 50 milliseconds (ms), with at least 45 ms between digits.

When Mostek set out to perform the decoding with a digital chip, they faced stiff competition. Most of the decoding today is done with a circuit like the NE567, phase-locked-loop, tone-decoder chip. The chip has a voltage-controlled oscillator (vco), which will phase-lock onto tone frequencies within a small range of its free-running frequency. When the loop locks onto the incoming tone, it multiplies the incoming sine wave by the vco's output in two different multipliers. One multiplier (A in Fig. 1) output is fed through a low-pass filter to the control voltage of the vco. Any error between the vco and the incoming tone sine wave will change the dc voltage on the control input to the vco. This changes the vco's frequency to match that of the incoming tone. This locks the vco 90° out of phase from the incoming sine wave. The other multiplier (B) receives the vco output an additional 90° out of phase from the first multiplier. This will produce a large negative dc voltage at the second multiplier's output. Multiplying two sine waves 180° out of phase will produce a negative dc component. The second multiplier's output is filtered and fed to the output pin of the 567. This pin will go from +5 volts to ground when it locks onto the incoming tone.

The phase-locked-loop decoding scheme requires that many resistors and capacitors keep their values in all environmental conditions. Each decoder (one is used for each of the eight tones) has one resistor and one capacitor which must be stable to keep the center frequency of the decoder accurate. This is the major disadvantage of the phase-locked-loop technique of decoding.

The MK5102N integrated-tone receiver uses a different scheme to decode the tones. After the high- and low-group frequencies are separated to their respective input pins on the chip, the zero crossings are counted in a specified time period. A number of these counts are taken and averaged over a longer time period. If the number of crossings matches that of a valid tone in both inputs, the digit's code is put onto the output latches (memory flip-flops that will not change after the tone has been removed). At the same time, the strobe pin (pin 4) goes high to signify that a valid tone is present. When the tone is removed, the strobe returns to a logical low, but the data pins (pins 7 through 10) will not change until the next tone is entered. Thus, one can use the strobe line to provide the interrupt to the microprocessor to stop whatever is in progress and pay attention to the receiver.

Instead of 16 frequency-determining elements of the phase-locked-loop system, the MK5102N uses an inexpensive, 3.579545 MHz, color-burst oscillator crystal as a frequency reference. The crystal is connected directly to the input and output pins of the oscillator (pins 2 and 3), with no additional components. This is an inexpensive temperature-stable crystal, which can be easily obtained and needs no fine tuning. Tests of the frequency-detection bandwidth of the receiver resulted in reliable detection of the tones ±3% of their center frequencies. This is one of the disadvantages of the receiver chip in that the detection width cannot be adjusted as it can for the 567 tone decoder. However, the receiver chip will decode well within the phone company's frequency tolerance, and thus should work well on all properly adjusted phone pads. The chip responded to tones within the 40 ms specified by Mostek, and required 35 ms between tones to successfully detect the sequential dialing of the same digit (such as hitting two 5s in sequence).

The real trick to operating the receiver is the prefiltering of the audio tones before they are injected into the integrated circuit. The standard tones consist of two groups. Each digit activates one frequency of the low group and one frequency of the high group, allowing for 16 possible combinations. Table 1 shows the digits and their frequency pairs.

The filter must separate the low-group tones to the low-group input (pin 11), and the high-group tones to the high-group input (pin 12). The tones are separated by low-pass filters separating the low group, and high-pass filters separ-

	High group (Hz)

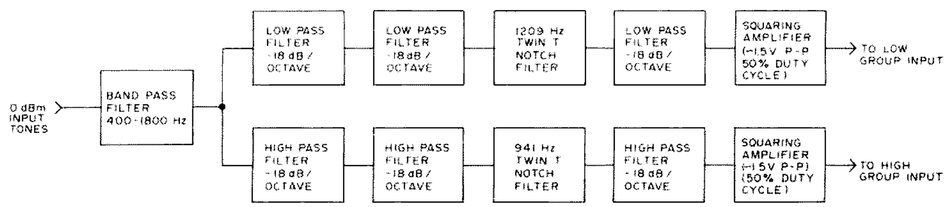

Fig. 2. Prefilter block diagram.

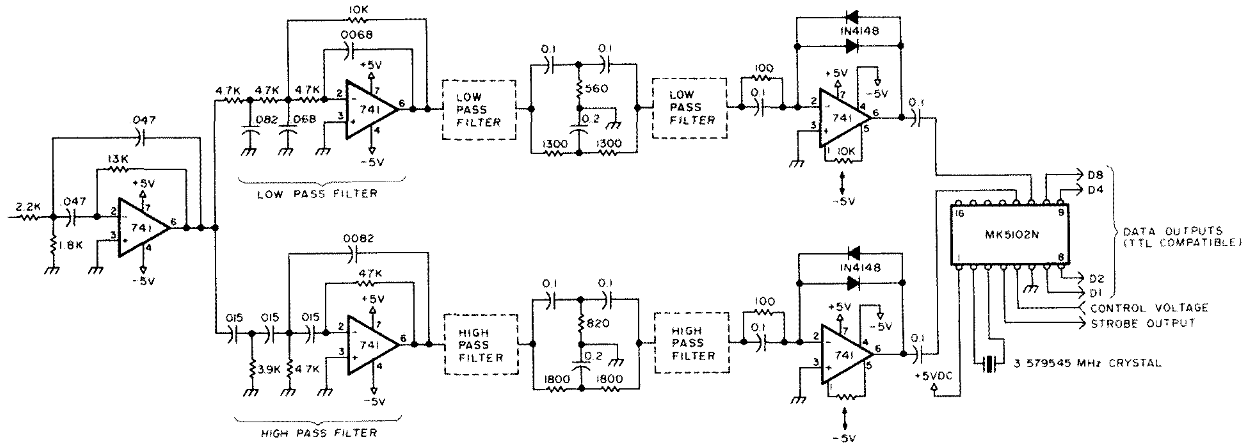

Fig. 3. System schematic.

ating the high group. The filters must separate the tones (which are input at approximately equal amplitudes, remember) by at least 33 dB (38 dB in the first-run engineering prototype chips). 33 dB is a voltage ratio of 45 to 1. Roughly, if the high tone is 1 volt rms, the low tone on the high input must be less than 20 millivolts rms. The prefilter block diagram is shown in Fig. 2.

The major filtering is done using active audio filters in a crossover filter. The crossover point was chosen at 1075 Hz, midway between the two groups. Each filter is a Butterworth filter with a roll-off of −18 dB per octave, and a 3-dB point at 1075 Hz. To sharpen the band edge, and also to help isolate the closest tones, the high-group high-pass filter string includes a twin-T notch filter between the second and third operational amplifiers. Similarly, the low-group low-pass filters include a notch filter in the same location. The notches are set to the closest tone of the other group. Therefore, the high-group notch filter is set to 941 Hz, and the low-group notch filter is set to 1209 Hz (approximately).

The prefiltering network begins with a bandpass filter with its gain down 3 dB at 400 Hz and 1800 Hz to eliminate noise and distortion products. The input is designed to take standard 0-dBm (across 600 Ohms) tones from the source. The gain of the input amplifier can be adjusted to meet these input levels, or the input bandpass filter can be redesigned to take other levels from the source. Lab tests of the filters shown in Fig. 3 showed successful decoding for tones from −½ dBm to +3 dBm. The output of each filter string is put through a squaring amp which should be adjusted for 50% duty cycle of the square wave into the receiver chip. The chip also includes two onboard operational amplifiers which were not used in this design. Production models of the onboard amplifiers should make them useful in the prefiltering network.

Fig. 3 is the complete schematic of the receiver system from audio input to digital output. All component values should be ±5%, and care should be taken to use high quality operational amplifiers. In Table 2, I have given the input and output characteristics of the system. The 4-bit binary code will be given at the data pins if the control pin (pin 5) is connected to the +5 volts dc, and the dual 2-bit row/column code will be given if the control pin is left unconnected. If the control pin is grounded, the output data pins will go to a high impedance state. This allows connection of many devices to a common data bus. If the other devices are in a high impedance state on their outputs, only the activated chip (i.e., raising the control pin voltage to +5 volts) will put data on the bus. This allows the same four wires to be connected to all the devices and saves a lot of wiring.

The design here uses ±5-volt dc power-supply voltages to be compatible with the repeater here at the University of Minnesota, WRØAQU. The 5102 will operate with a positive supply voltage of 4.5 to 5.5 volts dc. Use of higher supply voltages for the operational amplifiers may be desirable to prevent flat-topping of the tones by overdriving the amplifiers. This can occur if the tones come into the system at an especially high amplitude. This brings up one of the severest limitations of the receiver chip. If the audio system which delivers the tone to the prefilter distorts the tones, the first harmonic of the low-group tone will invade the high-group bandpass and cannot be filtered out. For example, twice 770 Hz is 1540 Hz, well within the high-group bandpass. Care must be taken that no clipping of the audio occurs, and that the audio system response from 500 Hz to 1700 Hz be reasonably flat. This will assure that the two tones arrive at the input to the prefilter at the same amplitude with little distortion.

The specification sheet gives a requirement of 12-dB signal-to-noise ratio, which I assume means that the noise must be at least 12 dB below the valid tones. To test this, a third sine wave was introduced, together with a valid tone at 0 dBm. The decoding became marginal with the third tone above −10 dBm. This easily meets the specifications of the 12-dB signal-to-noise ratio.

As a further test, I hooked the system to the speaker audio of an Icom 22A and monitored the output of a popular local repeater (WRØALU, 16/76) for a day. This repeater is very active and frequently used for autopatches. False detections were very infrequent (2 per day), and the dialed tones were decoded with good reliability. The number of false detections may seem excessive, but you must remember that chances are slim that the access code will be detected (1 in 8 per day for a single-digit access code), and that I was monitoring the audio after it had passed through the

repeater's transmitter and my receiver, essentially doubling the distortion of the tones. Tones sent simplex (i.e., not through a repeater) were decoded with excellent reliability (no observed errors).

I find the possibility of further computer control of the repeater exciting. The 16-digit DTMF code allows direct entry of hexadecimal code into a microcomputer system. The 16-tone pads are available for the stations which desire special control functions not on the 12-digit pad (which does not include the A, B, C, or D digits). We can use any phone booth on the street to call the repeater and issue control commands to the system. This is especially valuable when the receiver is faulty and will not respond to VHF signals.

The next challenge will be to complete the phone interface and the tone dialing system. Mostek has already marketed the 5086 tone-dialer chip, which will be used to regenerate the tones to meet the phone company's requirements. Circuitry and description of this system will follow in another article. I hope that you find the challenge of this technology interesting, and will join us in the world of the microprocessor.

I would like to thank Mr. Joe Jarrett of Mostek, Inc., for his help in getting this system running. ■

Computerize That Mailing List

—club secretaries, this is for you

Most amateur radio clubs produce some type of newsletter or bulletin on a more or less regular basis. These are usually generated by the efforts of a few members who have the desire, time, and other necessary resources to produce, reproduce, and distribute the club rag. Although some clubs simply hand out copies at each regular meeting, most of the larger, well-organized clubs maintain a complete and detailed membership list and mail their newsletter to all members on record a few days prior to the monthly meeting. Many of these clubs utilize the services of someone who has access to a computer system to keep their records and to print membership lists and even mailing labels each month. (Anyone who has had the dubious honor of addressing club bulletins by hand (month after month) can readily appreciate the convenience of using preprinted, peel-off, stick-on address labels.)

This article presupposes that your club has one or more people who either have their own microprocessor system or have access to a commercial system where time can be

had for little or nothing. Frankly, I doubt that there are many companies with their own computer system which wouldn't give a little free computer time to such a worthwhile and public service-oriented organization as an amateur radio club. I am talking about an amount of time on the order of ten to twenty minutes a month, depending upon the size of the club, the speed of the typist, and the kind of system used. Most companies should be happy to provide this kind of computer time in return for the goodwill and possible publicity.

Printer paper would be insignificant since most computer operators and programmers waste more paper in one day than your club would use each month. About the only expense that would have to come from the club coffer would be the special mailing labels with gummed backs. These will cost somewhere between $40 and $60 for 20,000 labels, depending upon the kind used and the particular supplier. That's enough to last a club with 300 members more than five years.

The primary goal of this article is to provide the necessary programs for anyone wishing to establish and maintain an amateur radio club membership file on any computer system that supports the BASIC programming language. The ham radio club membership system presented here consists of three programs. The first provides for the data entry and file maintenance functions necessary to add, change, and delete members' records. The second program prints a membership list, and the third program produces the mailing labels for the club bulletin.

Another goal of this article is to spark your imagination with a few examples of what else can be done for the club and its members by using spinoffs from the original membership list and mailing label programs. For example, suppose your club is located in a rather large metropolitan area and many of the club members would like to share rides with each other going to the club meetings (or carpool to work or to sidewalk sales, hamfests, and so on). Since all the address information is in the computer, why not have the computer print a special list of all the members in a particular sequence, such as by city? Even better, how about printing the list in zip-code order? Since zip codes are smaller divisions of cities and towns, a zip-code-sequenced list would show all of the hams who lived in the same part of town grouped together in the list.

Another interesting and useful way to print the membership list is by license classification. This would show all Novices, Technicians, Generals, and so on, grouped together by their respective classifications. This could be a valuable tool for the officers of the club in planning classes or special events, and could even save money in postage fees (something to consider carefully lately) if a special newsletter needed to be mailed only to those in a

Membership File List program.

particular group.

Other interesting, if less practical, ways of listing the members of a radio club include listings by first name (ever wonder how many Eds or Jims there are in your group?), by telephone number, or even in order of street address. Anything that is put into the computer record can be used as the "key" for any sorting sequence desired. But enough of that. Let's get back to the main subject.

The programs behind the mailing labels and membership list are very straightforward. The main idea is to provide the user with a fast and easy method of entering the necessary information into the computer. I have seen many systems that do not place much importance on that word "easy." All I can say is, if it's not easy to use, it's not going to get used.

File Maintenance Program

The first program is called the File Maintenance program. As previously mentioned, this program allows the operator to enter new members into the computer and to change any information already on file. It also allows the operator to delete members who don't pay their dues.

As with the other programs to be described, it is designed for use on an interactive computer system with a video display terminal (VDT). Punched-tape systems, as everyone knows, are now obsolete. Obviously, most 8-bit microprocessors fit in the interactive category, so don't think that you have to use a big time-sharing system. All you need is a computer (CPU), VDT, printer, and a disk storage device with enough capacity to hold all your data.

The File Maintenance program writes all membership data on the data storage disk. This information includes the usual: name, address, city, state, zip code, telephone number, and each member's callsign and license class. There also are three additional data items included in each member's record on the system described here. These may be used to record membership status or affiliations with other clubs or organizations (RACES, ARES, etc.). There is enough room for office telephone numbers or special remarks regarding type of equipment and operating capabilities. This part of the system is entirely open for whatever use your club might want for it.

One character position, for example, can indicate whether a member is "active," "inactive," "sponsor," "complimentary," "family member," or "life" member. By using, say, twelve character positions in the first "extra data" field, each member can be identified with twelve different groups in addition to the primary club. Obviously, this makes it possible for more than one club in an area to be supported by the same computer system using the same data file and programs.

Another type of information the club might wish to maintain could be the emergency capabilities of the members—subject, of course, to the consent of each member. (You gotta be careful what you put into the machine, lest it permit some unscrupulous use.)

Since the membership list is usually made available to the members, some of the "extra" data need not be printed on anything except the master listings used by officers of the club. Each club is different, and each one must choose whatever features are deemed most useful and desirable for its own purposes.

The File Maintenance program uses a direct-access disk file with the callsign used as the "key" to each record. The File Maintenance part of the operating system software automatically keeps each record in its proper sequence as each new record is added to the file. The callsign was chosen as the KEY simply because hams invariably use it for identification and each callsign is unique. A random-access data file must have a unique KEY for each record in the same file.

For those members who

Mailing Label program.

do not yet have their callsigns, the program simply uses the first four characters of their last name plus the first four characters of their first name for the actual KEY for those members.

By the way, much consideration was given to exactly which method should be used to "sort" the callsigns. One of the best known listings of callsigns is, of course, the *Callbook*. The sorting technique used for the *Callbook* is to take the call area number as the primary "sort field," followed by the suffix, and finally, the prefix. Actually, the *Callbook* uses a rather arbitrary and non-alphabetical sequence for the prefix in order to get the calls to come out by "age" of license. Now, with old 1 x 2 and 1 x 3 callsigns being reissued to recent upgrades, however, this method is becoming less meaningful and justified. Anyway, for sorting such a large national listing, I think almost everyone would agree that this technique is okay. I have found, however, that for smaller lists, a modified version works much better.

Since the members of any one club are usually local residents, their callsigns generally will all have the same area number. It doesn't make much sense, therefore, to separate a local listing by call area the way we would a national listing. With this system, each callsign entered is rearranged by the File Maintenance program so that the suffix comes first, followed by the prefix and the call area number. (No provision was made here to take care of foreign callsigns, by the way.) Thus, the actual KEYs in the data records are not exactly the actual callsigns but rather a special arrangement of callsigns which allows the computer to store the records in the sequence we want.

Some advantage was taken, when writing these programs, of the extensions to the BASIC language on our own system. Other systems which do not support these features can be used with only a few minor modifications, however, due to the general compatibility of BASIC from one machine to another.

Once a callsign has been entered, the File Maintenance program reads the disk file immediately to see if that callsign had been entered previously. If so, the information is displayed on the VDT. The user is asked what data, if any, should be changed. Thus, the program "assumes" that since the member is already on file, the operator must want to look at or change something in that member's record. If, on the other hand, that callsign is not already on file, the program proceeds by prompting the user to enter the next data item (the license classification). Each separate data item is entered in turn until all items have been filled in. At this point, the program asks if any corrections need to be made before continuing. If there are no errors on the screen, the user simply indicates "no"; the program writes that record on the disk and then asks for another callsign.

Club members who do not yet have callsigns are handled as follows: When the program requests the next callsign, the VDT operator simply presses the "CR/ENTER" key without entering any characters at all in the callsign field. The program then skips over the callsign and license classification fields and goes directly to the last name field.

The operator enters the last name of that member, then the first name, just as usual. As soon as the program has received both the last and first names, it combines the first four letters of the last name with the first four of the first name and uses this "string" of characters as the KEY for that member's data record in the disk file.

In any one club, there probably won't be more than one person with these same eight characters, taken the same way, who also don't have callsigns. Hence, these members can be assigned a unique KEY that not only gets them on file, but also even ensures that they will be listed alphabetically later, as we shall see.

There is some amount of "editing" performed on each data item entered. This is done merely to help ensure the validity of the data entered into the computer. For example, an address is usually more than three or four characters long. Any attempt to enter an address shorter than that will be considered a mistake. In case the user attempts to skip the address, the program will ignore such a silly thing and, instead, will repeat the request for a realistic address. If a member's address is temporarily not available, the missing data should be "flagged" by entering a long string of asterisks (or any other special character). That should attract the attention of anyone proofreading the list later, and they can collect the missing information. Similarly, the only valid license classes are N, T, G, A, and E. In addition to these five letters, the program also allows the operator to enter a "B" to indicate a club station or sponsor or a "?" to indicate that the class of the licensee is unknown.

Periodically, the Fort Worth Kilocycle Club runs a special program which changes all "?" to "N". This always gets an immediate response from those members who have failed to notify the KC Club of their actual license class.

Other items worth verifying include the state, zip code, and telephone number. Again, if this information is unavailable at the time, the operator should fill in these fields with something to catch the eye of the proofreader. The KC Club uses a string of 9s for missing zip codes and all 0s for missing telephone numbers.

When all items have been entered, the File Maintenance program writes the new (or modified) member's record on the disk and requests another callsign. If a member is to be deleted, the user keys in that member's callsign, the program displays the information on that member on the display screen, and requests the user to "ENTER ITEM # TO CHANGE, OR 'CR' TO CONTINUE:". The operator then enters the word "DELETE." The program will respond with the question, "DELETE WB5UTJ?" This gives the user one last chance to verify that this member is to be deleted. If the user enters the word "YES," the program will remove that record from the data file. Any other response will abort the delete request and the program will ask for another callsign.

For those members without callsigns, the user may either enter that special string of characters (first four characters of the last name plus the first four characters of the first name) in the callsign field or skip the callsign and enter the last and first names in the usual manner to display or delete members.

During data entry, if a mistake is made on any line, the user always has a chance to correct the error before going to the next line by backspacing to the mistake and retyping the data. If an error is not caught in time, the program gives you one last chance to correct any line, after all lines have been entered and before the data is written on the disk. (Entering the letter "X" in the class field indicates to the program that you want to reenter a mistyped callsign.) And, finally, entering END in the callsign field terminates the File Maintenance program.

I might mention here, for the curious, the purpose of the two different types of input statements used in the File Maintenance program. The READ statement and the READRECORD statement both get information input from the device specified (or implied), such as the disk or the VDT. The READ statement looks for "null entry" (CR) as the indication that the operator has entered a complete data item. The READRECORD statement is used whenever an entry of a specific length is expected, such as in the license class (one character only) or the state code, zip, code or telephone number. This statement also has the ability to verify that certain letters or characters have been entered. If the data entered via the READRECORD statement does not match the allowable response, the program automatically generates an error condition and the same statement (in this instance) is executed again and again until the operator enters a valid response.

The READRECORD statement also saves a few keystrokes by not requiring the user to hit the CR key after entering the appropriate number of characters for that input. While this feature may not save much time in this particular application, it is a good idea to use it wherever it would be appropriate for good programming practice. When large volumes of data are considered, this type of statement does indeed save a significant amount of time as well as reduces the probability of error.

Again, if these features are not available on your system, the program can easily be changed to accomplish the same purpose by simply using READ statements throughout, followed by the desired editing statements. By reducing the chances of the user entering bad data, the overall efficiency of the system can be increased greatly.

Membership List Program

The second program is simple and almost self-explanatory. It reads the membership file sequentially and prints the information that was recorded by the File Maintenance program. Since the callsigns were used as the KEYs to the data records, and since the system we use allows us to read direct-access files without specifying the actual KEYs, the members come out automatically in alphanumeric order by callsign. Those members without callsigns also come out in the proper order.

For readability, a space is inserted between the prefix/area and the suffix of each callsign. This makes it even easier to scan the list looking for a particular suffix or callsign.

The Membership List program prints the licensed members first, then prints those members without calls. This is done by the simple expediency of reading the file twice, passing over those members without callsigns on the first pass and skipping the others on the second pass. Although not the most efficient method according to professional programming standards, it is the easiest. Remembering how the unlicensed members were KEYed, you can see how they happen to come out in alphabetical order.

At the end of the job, the Membership List program prints a summary of the club's membership showing the total number of members broken down by license class. Thus, the club can see at a glance just how many Novices, Techs, Generals, Advanceds, and Extras they have. The summary information also includes totals for all family members, life members, sponsors, unlicensed members, and courtesy mem-

bers.

Mailing Label Program

The mailing labels are printed using a modified version of the Membership List program. The Fort Worth Kilocycle Club uses standard gummed-back labels arranged four-across on continuous form stock. This program reads four records at a time and then prints these four callsigns, names, and mailing addresses, four labels at a time.

The Mailing Label program first prints a few test lines for alignment, then, when the operator has adjusted the printer for correct alignment, begins printing the labels. This program arranges the callsign back into the correct format and even puts the first names in front of the last names before printing, for a more natural appearance. Clubs, sponsors, and other such "affiliated" members are printed last names first since they are usually entered differently than the others.

In order to save postage costs, the KC Club wanted to send only one bulletin to any household where more than one member lives. To accommodate this, the Mailing Label program was changed slightly to "sort" all records by zip code and address before printing the labels. Actually, as the Membership List program prints its own list, it also creates a new and separate file consisting of keys only. These keys are made up of the zip code plus the address of each member. When the Mailing Label program runs, it reads this special "sort" file sequentially to get the records, one at a time, in the proper order.

To eliminate duplicate mailings to the same address, the Mailing Label program simply skips any record having an address identical to the last one printed.

And Much, Much More

In addition to the regular membership list and mailing labels, the KC Club is getting some of the other benefits mentioned earlier. Once every year, the KC Club receives a copy of three separate listings. One is the usual roster with all members listed by callsign. One is an alphabetical listing of all the members by last name. And the third listing is in order of zip code for all those who might want to carpool or just want to know how many other hams there are in their neighborhood.

Recently, this particular listing turned out to be quite useful during a local emergency. On a Sunday afternoon, the elderly grandmother of a young lady ham radio operator walked away from the nursing home where she was a resident. The granddaughter and her husband (also a ham) requested the assistance of other area hams on the Fort Worth 34/94 two-meter repeater.

As usual, hams were both quick and numerous in response. Mobile operators thoroughly searched every area where possible sightings of the elderly grandmother were reported. The search continued day and night for five days.

When Jean Price WA5JCQ, the secretary-treasurer of the Fort Worth Kilocycle Club, heard of the situation, she realized that the many areas being reported as possible search areas might be covered much more quickly by hams who actually lived in those areas. And since she had that zip-code-sequenced list, complete with callsigns and telephone numbers of all the KC Club members, she volunteered to call all those members who lived in or near the areas where people reported seeing the missing lady.

Unfortunately, the woman had died the same day she left the nursing home, after walking less than a mile. At least one search party had covered a large area on foot and by helicopter not more than a mile away from where her body lay in the tall grass.

Although this search ended tragically, we all learned some valuable lessons during the ordeal. Perhaps one of the most useful lessons was the fact that we could use a computer listing of amateur radio operators, sorted by zip code, to reduce the time and effort required in search and rescue operations. Perhaps the same type of listing could be used in other situations as well.

Some of the extra information maintained on the KC Club's records includes which members have RDF capabilities. By "pressing a button" (or two), other programs not shown here can be run to give an up-to-date listing of all those members equipped to track down a jammer or bootlegger. This list goes to the local "SWAT" team commanders for use in coordinating RDF drills and, occasionally, the real thing. Fort Worth, Dallas, and the surrounding cities have some of the cleanest two-meter repeaters in the country. This fact may be due primarily to the nature of Texans, but credit must go to the well-equipped and well-organized T-hunters in the "metroplex," who have excellent track records.

These are only a few of the extra goodies (bells and whistles) available when a computer is used for the benefit of amateur radio. Future applications are endless.■

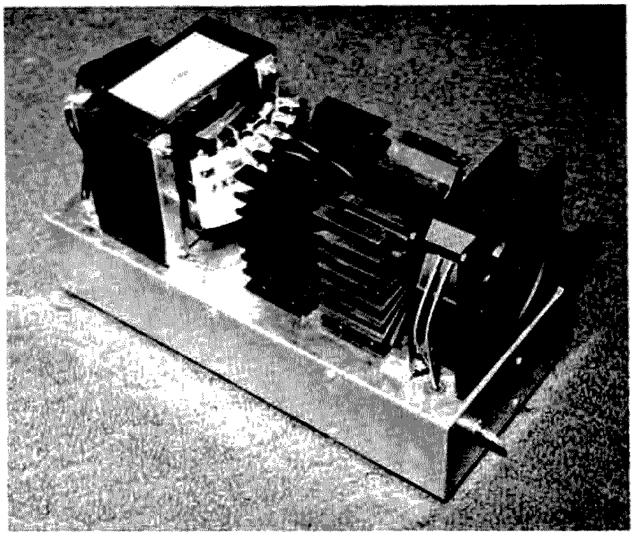
More Power to You

—12-V supply has current limiting, overvoltage protection, the works

With all of the solid-state transmitters, receivers, and transceivers on the market, power supplies to provide the proper voltage and current are sometimes complicated. There has been a need for a simple power supply design that provides overcurrent and overvoltage protection. Good components and design considerations are important if you are to have a reliable power unit.

The design which I will describe will allow you to adjust it to fit your needs. Most of the parts used are available from your junk box or local parts store. The hardest item to locate at a reasonable cost is a transformer. The voltage requirements for a good 13.5-V dc supply are a minimum of 36 V ac, center-tapped, or a single 18-V ac winding (see Fig. 1). For a 13.5-V dc regulator to perform, we have an upper voltage-sag limitation of 18 to 18.5 V dc under a maximum load. What we are asking the regulator to do is to maintain regulation at 13.5 V dc with a difference voltage of 4 to 5 V dc (13.5 V dc regulated + 5 V dc = 18.5 V dc unregulated). Keep in mind that this is the minimum voltage needed to maintain regulation. If you choose a transformer that yields a higher voltage difference (regulated to unregulated), the product of this difference voltage and load current, in power (heat), must be dissipated in the regulator, which we will discuss later.

If you have a solid-state rig you wish to power, check the manufacturer's specifications for current consumption. Choose a transformer which will handle that load current with a voltage level sufficient enough to maintain the unregulated supply requirements we discussed earlier.



Top view of completed supply.

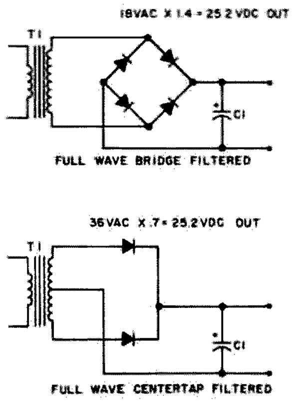


Fig. 1.

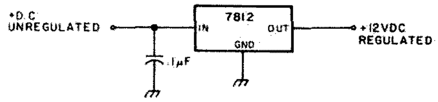

Fig. 2.

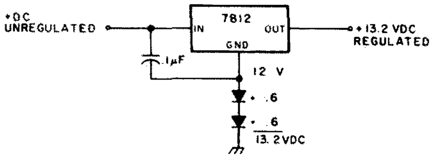

Fig. 3.

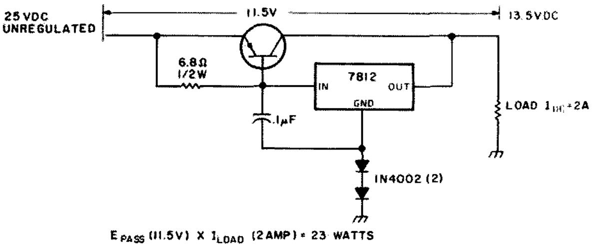

Fig. 4.

Select a diode assembly which will handle the I_{dc} output. My requirement was a maximum of 20 Amps to power a repeater and amplifier. My diode assembly will therefore have to handle 20 Amps. Each diode used will have a voltage drop of approximately 1 volt across it, and, at 20 Amps, P = I × E, or 20 Amps × 1 volt = 20 Watts. Heat-sink these devices well to dissipate this energy.

The filter capacitor may be gauged by a simple rule of thumb. For every Amp (I_{dc}) delivered, a minimum of 3000 µF of capacitance is required. You can have ripple in your supply and never notice it at the output of the regulator as long as the maximum ripple component never drops below the minimum unregulated voltage of 18 to 18.5 V dc. This capacitor value is arrived at mathematically, but, for simplicity, let's stick to the rule of thumb.

Now let's get to work on the heart of the supply. The key part of our regulated supply is a simple 3-lead positive regulator, an MC7812 that you can get at Radio Shack. This device will handle a maximum of 1 Amp alone, and has designed-in current limiting and short-circuit protection. See Fig. 2.

There are many manufacturers of this device who use prefixes other than MC, but 7812 is the device number. 78 is the design series and 12 is the regulated output voltage. You are about to ask a question! If I want 13.5 V dc, what am I doing with a 12-V dc fixed regulator? It is very simple. To increase the voltage of the regulator, we add one diode in series with the ground lead for every .6-V dc increase desired. See Fig. 3. These regulators vary slightly in regard to their actual regulated output voltage, but the additional diodes will allow us to select the actual voltage needed.

In Figs. 2 and 3, I have used a .1-µF capacitor. This capacitor is needed to stabilize the regulator from ground loops. Attach this capacitor as close to the regulator chip as possible.

As I mentioned earlier, this 3-lead regulator is capable of 1-Amp maximum output current. To achieve a higher current capability, we add a pass transistor. This device will give the current gain needed in the design. The pass transistor, or transistors, must handle the total output current of the supply. For this 20-Amp supply, I selected two 15-Amp PNP power transistors to do the job. One 20-Amp device would do it, but for a heat-dissipation safety factor, I used two.

Let's stop for a moment now and talk about the difference voltage I mentioned earlier. If we have an unregulated dc supply voltage of 25 V dc and a regulated output of 13.5 V dc, the difference voltage will be 11.5 volts. The product of the difference voltage and the load current will be the power dissipated, in Watts, by the pass transistor. For example, 11.5 volts × 2 Amps (load current) = 23 Watts of heat in the transistor. See Fig. 4.

My supply circuit requirement was 20 Amps. Now, 20 Amps × 11.5 volts is 230 Watts! That is a lot of power! The transformer is going to help in this dissipation, though. Fortunately, the unregulated voltage will sag, and we have selected a transformer that will only deliver 18.5 volts unregulated at 20 Amps. The difference between 13.5 volts regulated and the unregulated 18.5 volts is 5 volts. So, a 5-volt difference × 20 Amps = 100 Watts, which is a big difference! Using two pass transistors, we can dissipate 50 Watts in each device. With 50 Watts of heat to get rid of, you must use a good heat sink to pass this power into the air effectively. We must keep the junction temperature of the transistor below its maximum rating to keep from destroying the device. In this 20-Amp design, I used a 120-CFM muffin fan and two heat sinks that would handle 80 Watts using natural convection. By using forced air instead of natural convection, I could mount the heat sinks in any position. For natural convection, position the heat

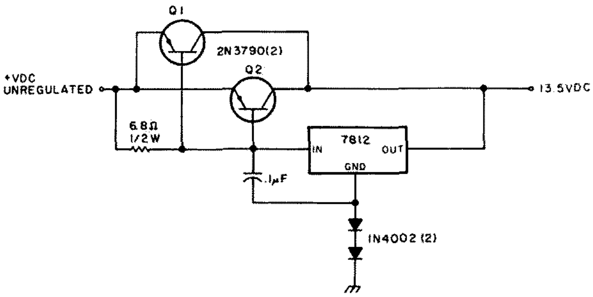

Fig. 5.

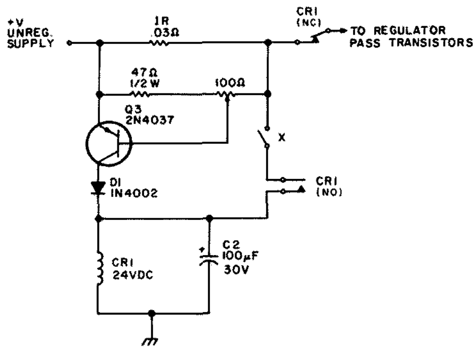

Fig. 6. Current limiter.

sink fins in a vertical direction.

Heat-sink considerations should be given to the 7812 regulator, also. At 20 Amps, and a maximum beta per transistor of approximately 50, we will have to handle a combined base current of 400 mA. The difference voltage of 5 volts will require a power dissipation of .4 Amps × 5 volts = 2 Watts.

Fig. 5 illustrates the complete regulator, including the 6.8-Ohm, ½-Watt resistor which is used to establish the bias of the regulator and pass transistors. Using collector feedback with this regulator chip proves to be very effective and stable. The supply will even be free of rf instability unless the regulator chip is involved in a concentrated rf field.

In the area of wiring, the only point of note is to use the proper size wire to handle the current in the high-current areas. Also, keep the two wire leads to the emitters of the pass transistors equal in length to allow balanced emitter current.

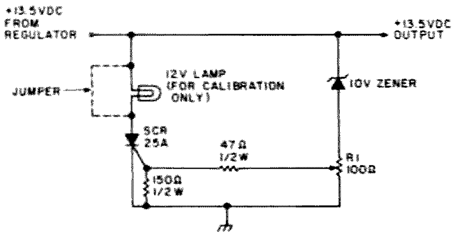

Fig. 7. Crowbar circuit.

We have discussed the regulator; now let's examine a current limiter. See Fig. 6. This current limiter operates instantaneously and it will only reset after the power is turned off and the supply bleeds down, or a reset push-button, normally closed, is added at point X. C2 should be sized to allow a delayed dropout, so relay CR1 does not buzz when it reaches the current limit. Resistor "IR" is selected so that the current-limit relay will trip at 20 Amps and higher, depending on the setting of the 100-Ohm pot. To operate, a .6-V dc drop is needed between the base and emitter of Q3. This voltage provides bias current which permits collector current to flow which, in turn, energizes CR1. CR1 must handle the total current of the supply even if it means paralleling contacts. To select resistor IR, use .6 V/20 A = .03 Ohms. This "resistor" turned out to be a coil of 14-gauge nichrome wire. By adjusting the 100-Ohm pot, we may now select a slightly higher current limit. If your supply is smaller, use .6 V/your current = IR. For example, .6 V/5 A = .12 Ohms. This resistor will drop some voltage, so rate the power carefully: P = .6 × 5 = 3 Watts, and remember the voltage drop. This .6 volts may not seem like much, but the minimum unregulated voltage is 18 V dc.

The last control circuit to design is called a "crowbar" circuit. Its intent is to protect your gear from overvoltage due to a regulator failure. See Fig. 7. In this circuit, we will select an overvoltage of approximately 15 volts. This is done by adjusting control R1 until the lamp just lights, and then backing the control off slightly until the lamp does not light. Remember, to turn off the lamp you must reset the SCR by momentarily disconnecting the lamp or turning off the supply. After this calibration, remove the lamp and connect the anode of the SCR directly to the output of the supply. If, during use, an overvoltage condition occurs, the SCR will conduct, the output will be short-circuited, and the current-limit circuit will turn off the supply.

In Fig. 8, you can now examine the whole circuit as I am using it in my 20-Amp supply. You may tailor your supply to the level of your needs with the information we have discussed. ■

Hit the Panic Button!

—a kill-switch system protects you and your shack

What would you do if you were operating away and noticed a wisp of smoke coming out of your new linear amplifier? Or if you were working on some gear and felt a whole lot of electrons running between your fingertips and your toes? Or if you were going on vacation and wanted to make sure your station wouldn't be operated in your absence?

You'd want to kill the power (I hope!), and in at least the first two cases, you'd want it off *fast*. And it might be even nicer if this could be done easily by somebody else, such as one of the kids—or even the dog—if you got into trouble and couldn't kill the power yourself. Aside from these situations, there are times when it is merely convenient to know that all your shack power is off.

A properly-engineered kill-switch system thus has a number of advantages, and if you have not yet installed this basic safety/convenience feature, you might consider it. In most cases it is a simple thing to do, it is economical, and whether or not you ever plan on using it, just getting it in place is guaranteed to give you a good feeling. At the very least, your station will have a new touch of class.

The basic circuit for a kill switch is shown in Fig. 1. It consists of three parts: a contactor (relay) in series with the main power line, one or more kill switches, and a reset switch. This last is nice if you ever wish to restore power once it has been killed. The circuit also shows a transformer, the purpose of which will be explained shortly.

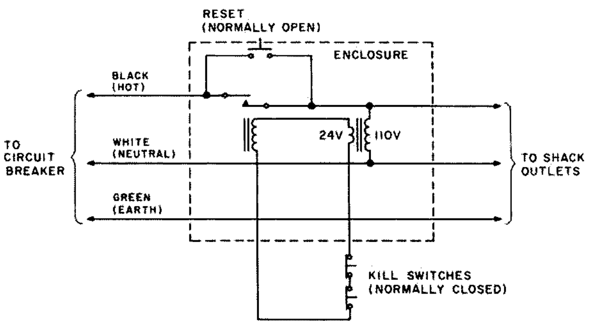

Fig. 1. Schematic for the kill-switch system. Only the hot wire may be interrupted—the neutral and earth wires must not be broken. Check with local authorities to verify respective wire colors in your locality.

The contactor is the heart of the system. It should have high-current-capacity contacts at least equal to the trip point of the circuit breaker feeding the shack, and preferably twice that. The reason is that the contacts will carry all the current your shack is using, and if it is necessary to kill power at a time of high-current draw, you will want the contact to open cleanly without arcing. Good reliable contactors (UL listed) are available from your friendly local electrical distributor.

The contactor should have a low-voltage coil; 24 V ac is a readily-available standard. This is so you won't have any unnecessary high voltage running around the shack to the kill switches. The transformer secondary voltage should match the contactor coil voltage; 24-volt bell transformers are readily available at low cost. You also can use 12 V ac, which is a standard and readily available, but the current draw by the contactor coil will be about twice as much and it will tend to get warm. Whatever you use, the contactor should be rated for continuous duty, both in the coil and in the contacts.

The kill switches are normally-closed push-button switches, and they should be located so they are easy to get to and easy to operate. I prefer industrial-grade actuators with big red push-buttons (3" or so in diameter) so they can be hit easily with an entire hand—literally, "panic buttons." On my own service benches, kill switches are located so they also can be hit easily just by moving a knee. If you use more than one kill switch, they're just wired in series, as shown in Fig. 1. Industrial-grade switches are highly recommended because what is most important is reliability. It would be mortifying, to say the least, to smash one in panic and then discover it didn't work because you broke it!

The reset switch is a

A Powerful Plus For Your TR-2200A

—improved supply/charger is a first-rate addition

Two versions available.

After using my new Kenwood TR-2200A for a few days, I discovered that its standard battery power and charging setup was rather inconvenient for a heavy usage cycle. It was not possible to listen or transmit while charging the batteries, and I found that, invariably, the batteries were always near complete discharge whenever I had an important use for the transceiver.

I am sure other hams who monitor 2 meters extensively have run into this same problem of running down the batteries on receive, with no power to spare for a needed transmission. The charging cycle naturally takes about 16 hours, which uses up 8 hours of daytime activity as well as 8 hours at night. The net result is at most 8 daily hours of operation, provided the batteries stay charged that long.

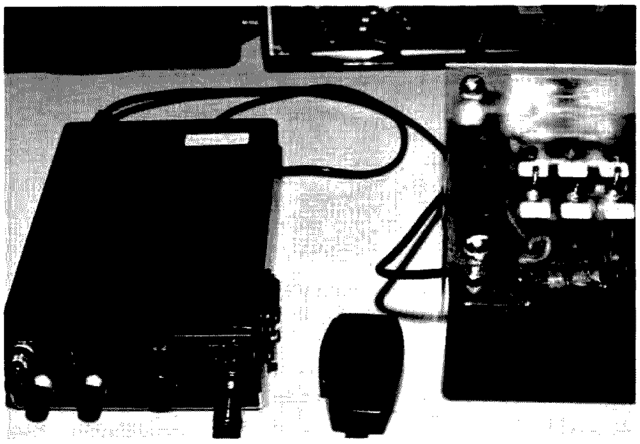

Photo A.

The Solution

To help myself out of this frustrating situation, I developed the circuit shown in Fig. 1. It consists of a regulated 12.6-V-dc source rated at 1 Ampere, a battery-charging source, and an automatic charger shutoff circuit. The 12.6-V supply is used to continuously power the TR-2200A for receive and transmit. During operation on the 12.6-V supply, the batteries also can be simultaneously charged by the flick of a switch (SW3). The charger source provides a current of roughly 45 mA (.1C) into a nominal battery voltage of 13 volts, which is the same current provided by the Kenwood charging unit. As an additional feature to avoid that nagging mental question, "Are my batteries charged yet?", I added a voltage sensing circuit that automatically terminates the battery charging when the battery voltage reaches a predetermined level. The charging shutdown voltage is adjustable and set by the trimpot, R4. Battery charging and automatic charging shutdown can be used regardless of whether the TR-2200A is switched on or off. Three LED indicators constantly monitor the regulated dc output and the charging circuit. LED L3 glows when the batteries are up to the voltage set by R4, indicating that charging has been completed.

Circuit Operation

The transformer, T1, in conjunction with D1-4 and C1-2, provides a raw dc source of approximately 17 volts. C1 and C2 have a total capacitance of 16,000 uF to assure minimal ripple and droop in the 17 volts when large amounts of current are being drawn from IC1. Remember that the TR-2200A draws about .7 of an Amp during transmit in the high power mode. The raw 17-volt source is used to power both the IC regulator and the charge circuit. IC1 provides a stable 12-V supply, and diode D5 acts as a booster to give a total regulated output of 12.6 V. C3 and C4 are high-frequency bypass capacitors and are necessary to ensure stability in

 Aug 1979

normally-open push-button switch, but can be any other type of switch as well. It needn't be especially reliable or easy to get to, but it should not be located far from the contactor because it will have high voltage (110 V ac) on it. Like the kill switches, the reset switch need have no great current-carrying capacity.

The contactor should be mounted in an enclosure, UL-approved, of course, near where the power line first enters the shack. The transformer and reset switch can be mounted near the enclosure, or on it, using knockouts, depending on the enclosure you get. The whole thing can be placed inside a locked box, if desired, to prevent unauthorized access to the reset button. The 24-volt line (or whatever low-voltage line you have selected) just runs out of the box/enclosure. Very simple.

When wiring up the contactor, a few safety precautions are in order. First, make sure power is off at the circuit breaker, and *verify* that it is off by means of a portable lamp or circuit-tester inside the shack at the point you plan to cut into the power line. Secondly, make sure you insert the contacts into the hot side of the power line, not the cold or "neutral" side. In most localities, the black wire is the hot and the white wire is the neutral. You never, ever, want to put a switch or any other kind of interruption into the neutral.

If you find a green wire also, don't cut it! It is the earth wire, and if it gets broken, you may have all kinds of problems in all sorts of places where you don't want them when you don't want them. (You may even find your trusty soldering iron is frying you as well as the solder, for instance. Not much fun.) If you have any doubts about the color coding, check with your local power company or a local electrical contractor. Note: In some communities it may be required that a licensed electrician actually make the connection for you and/or that the result be inspected by the local building inspector.

Once the contactor is wired up, just run the low-voltage line through the kill switches and you're in business. Now, and only now, you can turn shack power back on at the circuit breaker. The shack will still be dead, however, because the contactor contacts are open and thus there can be no voltage on the coil to energize it. Pressing the reset button applies 110 volts to the transformer, which supplies the low voltage to the contactor coil (through the kill switches), energizing the contactor and closing the contacts. The contactor will remain energized when the reset button is released because the transformer—like all the other equipment in the shack—is now getting its primary power through the contacts.

And there you are! With luck, you've got a nice new convenience for the shack. With somewhat less luck, you've got a simple system that'll keep you from having no luck at all. Just one final point: Teach the family how to kill power if they ever need to. If you ever need assistance, smashing one of the prominent red buttons should be the first thing they do, and such a time is definitely not the time to explain the system to them. ■

the 7812 regulator. Fuse F2 and zener D6 act as a crowbar circuit to open up the dc source to the TR-2200A, should the voltage rise above 15 V. This could happen, for example, if IC1 shorted and provided 17 volts to its output terminal. F2 and D6 protect the TR-2200A from exceeding its maximum input voltage of 15.8 V, since D6 will draw enough current to blow F2 at elevated voltages. At a normal output level of 12.6 volts, D6 does not conduct enough current to affect the circuit.

The battery-charging current is provided by R2 in series with the 17-volt source. When SW3 is switched on, current flows through R2, SW3, and the normally-closed contacts of K1 to the battery in the TR-2200A. Note that the battery pack is disconnected from the rest of the TR-2200A circuits when the power cable is plugged into the back of the transceiver. This allows simultaneous but independent operation of the rig and charging of the batteries.

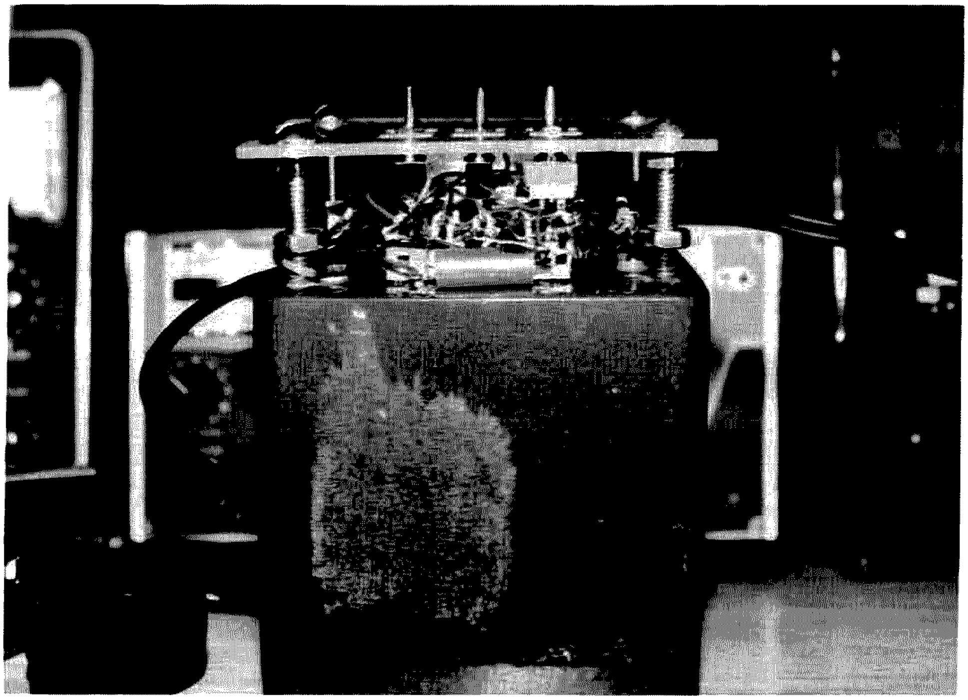

Photo B.

The automatic charging shutdown is provided by the differential amplifier (Q1, Q2, Q3) and the relay, K1. If switch SW3 is turned on when the nicad battery voltage is less than the voltage set at the base of Q2, then Q3 and K1 are held off and the contacts of K1 remain closed. When the battery voltage rises during charging to within about 10 mV of the "set-point" voltage at Q2, Q3 will conduct enough to turn on K1 and open the charging circuit. The shutdown has a positive latch since opening the contacts of K1 causes the voltage at the base of Q1 to be pulled up to 17 volts by R2, which guarantees that K1 will remain energized. While K1 is being driven, indicator L3 will glow, showing that the battery charge cycle is complete. R5, R4, D7, and C5 form a reference set-point voltage for the differential amplifier. R8 is a protection resistor to prevent high current burnout of the batteries should Q1 and Q2 develop shorts. D8 prevents L2 from glowing when SW3 is in the off position. Without D8, L2 can glow due to breakdown current flowing in the reverse biased base-emitter junction of Q1.

Switch SW2 defeats the automatic charge circuit by shorting the contacts of K1. Note that in this manual charge mode, indicator L3 still glows whenever charging is complete and the battery voltage is up to the set-point level. SW2 also has another important practical function. When the TR-2200A is used for transmitting, the auto shutdown circuit tends to get falsely triggered when the battery is close to the final set-point voltage. This is due mostly to the sagging of the 17-volt supply during transmit, which changes the voltage at the base of Q2. Although I managed to eliminate this problem electronically, the additional transistors, etc., that were required could not compete with the simplicity or the cost of the single toggle switch, SW2. In addition, the manual mode seemed to be a worthwhile feature for certain charging situations.

Construction Details

I used a free-form chassis-less technique to build up the dc supply/charger circuit. This was mostly due to a lack of a chassis in my junk box, but it was also due to an unwillingness to complicate a simple project with a lot of sheet metal work. The circuit will work with just about any construction technique, so you can use epoxy PC boards and painted cabinets if that makes you feel more comfortable.

There are a few construction items that deserve special attention. The regulator package will dissipate about 3.5 Watts under full transmit load and thus needs to be mounted on a heat sink. The thermal resistance of the heat sink should be less than 20° C/Watt. I used a small piece of scrap aluminum (2" × 3") bent into an L shape, which runs fairly cool under all conditions. The builder can experiment with any heat sink materials he has available to keep the regulator temperature down.

It should be noted that the mounting tab of the 7812 regulator is not at ground potential and will have to be insulated if a metal chassis is used. Also, bypass capacitors C3 and C4 should be mounted very close to the 7812.

Photo A shows a picture of the completed supply unit with the TR-2200A. The power transformer provides a mounting base for all components, including a Plexiglas™ panel for the toggle switches and LEDs. Nearly all of the circuit was built up on two terminal strips which were epoxied along with the heat sink and fuse holder to the top of the transformer case. Cable ties were used to mount the 8,000-uF electrolytics to

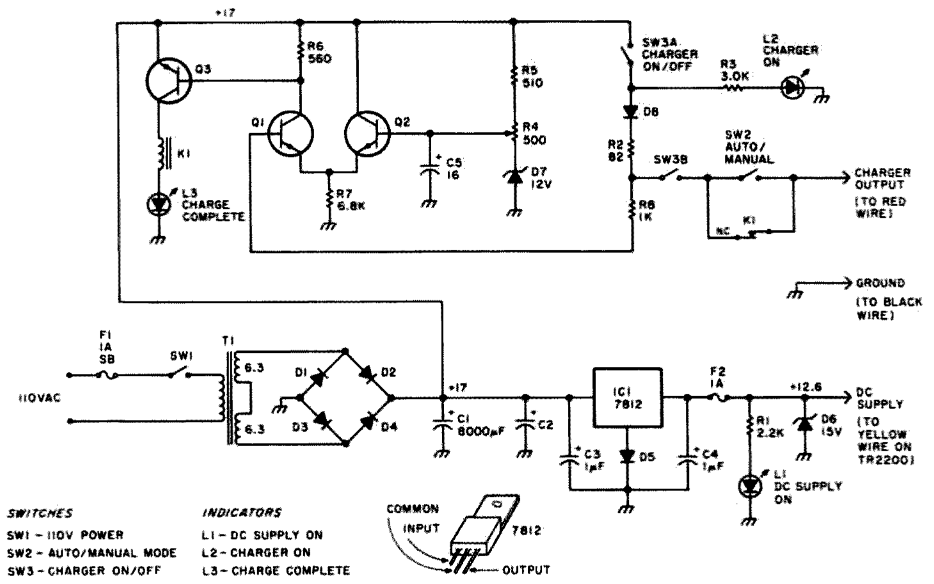

Fig. 1.

the back of the transformer. Hardware that mated with the mounting studs of the transformer was used to support the Plexiglas switch panel. The components in the differential amplifier were "space wired" to simplify construction.

About the Parts

The parts to build this unit are fairly noncritical and should be available at a low cost from your neighborhood surplus dealer. I managed to build up my supply from junk box components.

There are three parts items that deserve discussion. Relay K1 must be operable at a coil voltage between 5 and 12 volts and a current of <10 mA. This is due to the 17-volt supply used and the current available from Q3. My relay was a reed type and had a coil resistance of 3k. The builder should be able to find a surplus relay that will do the job. Remember, however, that normally-closed contacts are used in the circuit, so an SPST type will not work.

The transformer secondaries should be rated at more than 1 Ampere to ensure low IR drops in the windings. The total drop in ac voltage with a 1 Amp load on the secondary should be less than .5 V below the nominal to assure a stable 17-volt supply. A surplus filament transformer rated at 3 Amps should be adequate, but experimentation here by the builder is definitely encouraged.

The values of C1 and C2 are fairly arbitrary and can be changed by a factor of two with little performance change. If you buy these items, try to get all the capacitance in one unit to simplify construction.

Adjustments

R4 is the only adjustment in the supply. To adjust it, put an accurate (high-impedance-type) voltmeter from the base of Q2 to ground. Set the voltage for 14.0 volts so that the charger will shut down when the individual cell voltage in the TR-2200A battery pack is 1.40 volts (there are 10 batteries in the pack). According to the GE *Handbook*,[1] the cell voltage will increase above 1.40 volts at the beginning of an overcharge condition, and the 14.0-volt setting I have suggested above is based on this information. An alternate way to adjust R4 is to allow discharged batteries to charge for 16 hours and then to adjust R4 until the charge complete lamp just comes on. Some experimentation may be necessary to get the best voltage threshold for your rig.

A Low-Cost Alternative

If you are interested in building this dc supply/charger but do not want or cannot afford all of its features, a stripped-down version is easily derived from the complete unit. Just eliminate all components except those with an * on the parts list. This basic unit will still provide a dc supply and simultaneous charging, but does not incorporate any safety or convenience features.

Regardless of which version you decide to build, I am sure you will find this supply to be a valuable accessory to your TR-2200A. For those of you with other kinds of battery-operated rigs, I am sure they could be configured like the TR-2200A to make use of this circuit.

As far as I have been able to learn, a supply of this type is not now commercially available, and I would enjoy working with any enterprising group that would like to manufacture the unit. ■

Parts List

*T1	Filament transformer 12.6 V ac @ 3 Amps
*IC1	7812 fixed voltage regulator: 12 Volts
Q1, Q2	2N3904 NPN transistor
Q3	2N3906 PNP transistor
*D1, D2, D3, D4	Silicon diode 100 piv @1 Amp
*D5	1N914
D6	Zener diode 15-volt, 400 mW
D7	Zener diode 12-volt, 400 mW
D8	1N914
*C1, C2	8000 uF, 20 V
*C3, C4	1 uF tantalum 35 V
C5	16 uF, 20 V
R1	2.2k ¼ W 5%
*R2	82 ½ W 5%
R3	3.0k ¼ W 5%
R4	500-Ohm trimpot
R5	510 ¼ W 5%
R6	560 ¼ W 5%
R7	6.8k ¼ W 5%
R8	1.0k ¼ W 5%
K1	Relay, SPDT, dc coil 5- to 12-volt @ 5 mA
F1	Fuse 1 Amp delay type
F2	Fuse 1 Amp
*SW1	SPST toggle switch
SW2	SPST toggle switch
*SW3	DPST toggle switch
L1, L2, L3	LED lamps, choose your own colors

Build a Wide-Range Rf Resistance Bridge

—with a multitude of uses

Putting theory into practice.

William Vissers K4KI
1245 S. Orlando Ave.
Cocoa Beach FL 32931

Excellent articles on rf resistance bridges have appeared in various publications, particularly one by Jerry Sevick in the Nov., 1975, issue of *QST*. However, my own analysis showed that a wide-range bridge would have many applications rather than the few for a bridge designed to measure a small range of resistance for a specific purpose.

The bridge I designed is simple, and easy to build, use, and calibrate. Its direct reading feature eliminates the need for an auxiliary chart or graph that can easily get lost or damaged. The versatility of the bridge makes it a worthwhile addition to any amateur station. The basic theory presented will outline how wide range is easily obtained, and the detailed description of its different uses will prove its value.

The Basic Bridge

Fig. 1 shows the wide-range bridge principle explained by a simple numerical example. The two legs of the bridge, R_A and R_B, are made up of a single variable 100-Ohm two-Watt linear potentiometer. R_C is a half-Watt 50-Ohm carbon resistance. R_X symbolizes the unknown resistance we wish to measure. E is a voltage source, and I is the meter I will measure our null with when the bridge is in balance.

Without going into a lot of bridge theory and proofs that can be found in any textbook, all we need to know is the basic bridge equation for a balanced condition, which is: $R_X/R_B = 50/R_A$. Solving for R_X, we find that $R_X = (R_B)(50)/R_A$. Now, as I've already said that R_A and R_B are nothing more than a 100-Ohm potentiometer, let us set the potentiometer near one end of its travel so that R_A is equal to ten Ohms. Then R_B will be equal to 100 − 10, or 90 Ohms.

Now, if we set the potentiometer near the end of its travel so that R_A is equal to 90 Ohms, we find that R_B will be equal to 10 Ohms. And, solving for R_X, we now find that $R_X = (50)(10)/90 = 5.56$ Ohms. These calculations show that a wide-range bridge design can be achieved quite easily.

I know that already some of you will be saying, "Why don't you run the potentiometer to zero for both calculations just shown and come up with a bridge with a range of from zero to infinity?" That is a very good thought, but we do run into some practical limitations. We would find that our bridge sensitivity would have dropped to zero, for one thing. And secondly, as there is no such thing as zero resistance when the potentiometer is at the end of its travel, our actual bridge range is somewhat less than zero to infinity. But with a small transistor amplifier we can easily increase the basic bridge sensitivity. And this increased sensitivity also allows our exciting voltage to be anything from an ordinary rf signal generator, to a grid-dip meter, to a simple low-powered variable-frequency oscillator. If a grid-dip meter is used, a single turn coupling coil attached to the bridge input jack will provide plenty of excitation voltage. In my own case, I use a Heathkit® Model LG-1 signal generator with a maximum output

of a tenth of a volt. This is adequate for proper operation of the bridge. So, if care is taken in our calibration, we can come up with a wide-range bridge sufficiently accurate for all amateur usage.

The Actual Bridge Circuit

The basic bridge circuit just described is used in the final circuit of Fig. 2. As in all rf circuitry, every effort should be made to keep the internal bridge leads as short as possible to avoid excessive lead inductance and capacity to ground. The input and output coax jacks are about an inch and a half apart on the chassis. This allowed very short leads to be used.

A pair of binding posts, A and B, are in parallel with the output jack J2 so that calibration resistors and wire-connected leads can be easily connected without having to use clip leads or other methods of connection. The 1N34 diode detector rectifies the nulling voltage and feeds it to the transistor amplifier through a 4.7k resistor, along with a couple of .01-uF bypass condensers. The transistor amplifier circuit was about the simplest one I know; it is a standard differential amplifier.

The transistors used were a couple of surplus PNP 2N396As donated by my buddy K4YS. Any standard general-purpose transistor will work as well, although it may be necessary to use another value of resistance for R4 of Fig. 2. In my own case, I temporarily used a variable 25k resistor for R4 and adjusted its value until the amplifier gave the gain and stability I desired. Then the variable resistance was measured with an ohmmeter, and a fixed value used in its place in the circuit. It's a quick and easy way to optimize a circuit. The variable 10k potentiometer R2 used for balancing the meter current to zero during the initial null was an available 2-Watt potentiometer, although a small trimpot can be used if desired. R3 is a 2-Watt potentiometer-type variable resistance used as a sensitivity control that limits the current through the 50-uA microammeter when setting for initial null. Switch S1 turns the transistor amplifier "on" or "off". Switch S2 allows the transistor amplifier to be used for other purposes, as will be described later on. The entire bridge is self-contained in a 7" x 5" x 2" chassis. A coat of gray enamel paint gives it a professional look. I have found that painting the chassis before final assembly and baking it in the kitchen oven for about fifteen minutes at 250 degrees Farenheit produces a hard, smooth finish.

Calibration

The simplest way to make the bridge direct-reading, which avoids the use of separate calibration curves, is to paste a piece of white cardboard directly on the chassis under the 100-Ohm potentiometer knob. This allows actual values to be inked in when the calibration is made. Fig. 3 is a theoretical calibration sheet illustrating the method just described. Theoretical values were shown, as every individual calibration will vary somewhat depending upon the linearity of the 100-Ohm potentiometer and the actual values of the resistance of the potentiometer at the ends of its travel.

I had mentioned earlier that this resistance will not be zero, and its actual value does affect the calibration points obtained. However, I did find that in my case there was close agreement between theoretical and actual values within the range of 10 to 400 Ohms. In any event, the actual values obtained during calibration will allow you to read well beyond the values just mentioned. Naturally, reproducible accuracy will not be as great at the extreme ends as at the middle of the resistance range. As in all instruments, the calibration is only as good as the standards used.

The calibration standards used were ordinary 5% tolerance small fixed carbon resistors. The calibration technique is very simple. Connect the calibration resistance selected across binding posts A and B. Set the balance control to about the midway position, and

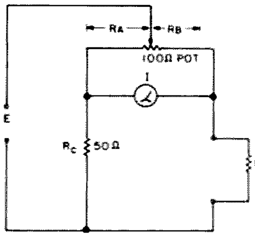

Fig. 1. Basic wide-range bridge.

set the sensitivity control to minimum sensitivity (maximum resistance). Turn the power switch to the "on" position. Now adjust the balance control until the meter reads zero. Apply an rf voltage from the signal generator to J1, the input jack. The signal generator frequency I used was 3.75 MHz, although the frequency is not important since the basic bridge is not frequency-sensitive. The meter will read some current. Adjust the 100-Ohm bridge potentiometer until a null is obtained. Now the sensitivity control can be increased to maximum sensitivity, and the output of the signal generator can be increased as desired. The bridge potentiometer is now rotated until the best null is obtained. The dial scale can now be marked for the calibration resistance value. As many calibration points as desired can be obtained in this way. The zero resistance point can be obtained by shorting the bind-

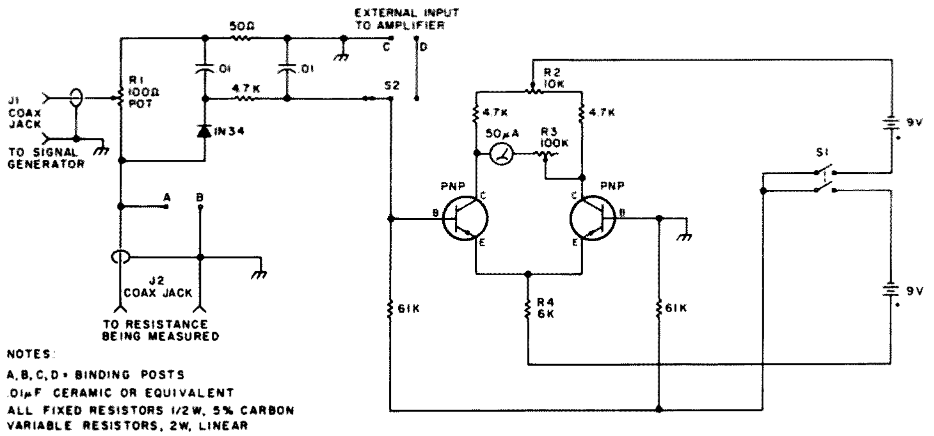

Fig. 2. Wide-range rf bridge.

ing posts and observing the null. The infinite resistance calibration point is found in the same manner except that the binding posts are left open. In both of these instances, the null will be poorer than those obtained at other points on the scale.

Actual Uses of the Bridge

Although the bridge is normally used to measure rf resistance, its wide range allows it to establish other measurements where the actual resistance values are of secondary importance. Therefore, I am going to include those items which make the bridge so useful under these circumstances. These secondary uses are of great value, not only for obtaining specific data, but also in tying many theoretical concepts we read about to simple observations that we are now equipped to make. In almost all rf measurements, the circuit being checked is frequency-sensitive so that at resonance the circuit becomes a pure resistance. Knowledge of the resonant frequency is read from the signal generator. The resistance value read from the bridge will provide sufficient information for almost any problem that the amateur may want to solve.

Antenna resistance at resonance:

Connect your antenna coax line to J2 and apply rf voltage from the signal generator. Establish a first approximate null by rotating the 100-Ohm potentiometer knob on the bridge. Then vary the frequency of the signal generator until the null is more pronounced. The final nulling consists of adjusting both the frequency of the signal generator and the variable control on the bridge. This is necessary to obtain the best null. At the lowest null obtained, the resistance will be the antenna system resistance, and the frequency will be its resonant frequency. I was careful to say antenna system, as this is defined as your antenna with the normal coax feedline attached. If for some reason you want to know the actual antenna resistance, then your feedline will have to be an electrical half wavelength long. The reasons for this are covered more fully in transmission line theory, and are considered a bit too much for the scope of this article. But, as we shall see shortly, our bridge will easily measure an electrical half or quarter wavelength of coax line if this information is needed.

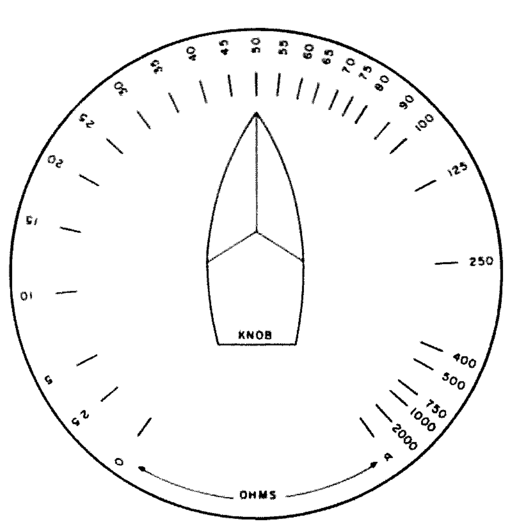

Fig. 3. Direct-reading bridge scale.

Tuning your matching unit:

This bridge is a wonderful device to allow you to load your transmitter to exactly 50 Ohms without even putting a test signal on the air. You no longer have the worry of inadvertently loading up into a high swr condition and possibly damaging your final. At the same time, you can't create any unnecessary QRM on our already crowded bands. And once you've done this for any frequencies, just note the dial settings of your transmitter and matching unit, and you can quickly put your transmitter on and be assured that you will be perfectly matched. First off, load up your transmitter at the desired frequency into a dummy load. (Normally, this is 50 Ohms.) Then connect J2 to the input of your matching unit, and connect the output of your matching unit to your antenna system. Select the frequency you just tuned up your transmitter to on your signal generator. Then set the variable 100-Ohm potentiometer on your bridge to 50 Ohms on the calibrated scale. Turn up your bridge, and adjust your matching unit until the best null is obtained. Presto! You are now completely tuned up. You don't have to touch your transmitter tuning or loading at all. Just reconnect your transmitter to your matching unit input and you are finished. Actually, I can do the above more quickly than I've written about it. And in addition, when you are done, you can't even see your swr meter or reflected power meter wiggle when you put your transmitter on the air. It's really fun to amaze your friends by obtaining such a perfect match, quickly and scientifically, and without any QRM on the air. It's tuning up your station in a really engineering fashion.

How good is your matching unit?

From the preceding step it is easy to go a bit further and establish the resistive matching limits of your tuning unit. It's a quick method of comparing one kind of a unit against another. I'm sure we all agree that to define the limits of a matching unit as "being able to load into a random wire" is not a very exact technical description. This is particularly true since random could mean anything from a couple of feet to a couple of wavelengths. I've found in my own case that my bridge has allowed me to design a wide-range matching unit, and quickly establish which variables are important to obtain the wide range I desired for my specific antenna needs.

All you do is see what the resistance limits are that your matching will load into and still retain 50 Ohms at the input jack. The technique is very easy. You can use your 5% calibrating resistors for this purpose. Just connect a resistance to your matching unit output and jack J2 of the bridge to the matching unit input. Set the bridge resistance knob to read 50 Ohms on the scale. Now adjust your matching unit until you can achieve a bridge null at the frequency of operation you have selected on the signal generator. In this way you can quickly determine the upper and lower resistance loading limits of your matching unit. If the resistances you select are too high or too low, you will not be able to obtain a satisfactory null on the bridge. My home-built matching unit matches from about 10 to 200 Ohms without any difficulty. Generally speaking, the wider the resistance range, the wider the range of the matching unit for varying impedances. And you'll be

surprised to find the different ranges obtained by different kinds of matching units. It's an education in itself.

Resonant frequency of tuned circuits:

The ease with which the bridge can determine the resonant frequency of a totally enclosed tuned circuit is quite amazing. And it will even tell you whether or not it is a series-tuned circuit or a parallel-tuned circuit. All you need is two leads from the circuit being tested. Connect the leads to output binding posts A and B. We know that if a circuit is a series one, its electrical resistance will be low. So, just to obtain the best null, vary the signal generator frequency and the 100-Ohm control at the low resistance end of the scale. At the best null obtained, the signal generator frequency will be the resonant frequency of the tuned circuit. The resistance reading will be its equivalent series resistance.

The parallel circuit is measured in the same way, except that the bridge potentiometer is at the high end of the scale. The resistance value measured will be the equivalent parallel resistance of the tuned circuit. And, as before, the signal generator will indicate the resonant frequency of the tuned circuit. I mentioned that the tuned circuit could be completely enclosed. This bridge can measure resonant frequencies where it would be impossible to inductively couple in a grid-dip meter to make a similar measurement.

Measurement of velocity factor of coax cable:

The technique of measuring the velocity factor of coaxial cable is simple when it is realized that an electrical quarter wavelength of line (or odd numbered multiples thereof) open at the far end acts like a series-tuned circuit at the near, or measured, end. Just connect your piece of coax cable to J2 and null the bridge at the low resistance end of the scale, at the same time varying the signal generator frequency for the lowest frequency for the best null obtainable. The equation for velocity factor in this case is: Velocity factor = (length in feet)(F_{MHz})/246 for a quarter-wave section of line. And now, as an experiment, if you triple your signal frequency, your line will again null the bridge. It is now acting as a three-quarter-wavelength line. In this way, it is very easy to demonstrate basic transmission line theory.

The same principle is used in determining the electrical half of a line open at the far end. This condition is equivalent to a parallel-tuned circuit. Just adjust your bridge null at the high resistance end of its scale, and at the same time adjust your signal generator for the lowest frequency that will give you the best null. The velocity factor can be checked and the formula will be velocity factor = (length in feet)(F_{MHz})/492 for a half-wave section of line. You can also use this method for setting up for a half-wave section of line if desired.

Characteristic impedance of coax cable:

The characteristic impedance of a coax cable can easily be determined with the rf bridge. All you do is connect one end of the cable to J2 and connect a selected resistor across the other end of the cable. The selection of this resistance is such that when the signal generator frequency is varied there is no change in the bridge reading. At that point, the resistance selected is equal to the characteristic impedance of the coaxial cable. It is an easy matter to try several different values of resistance to terminate the cable, so that a variation of signal generator frequency will show no change in the meter reading. The null can now be obtained, and the resistance reading will be the characteristic impedance of the cable. The value read will be equal to the terminating resistance at the end of the line. This illustrates the basic principle that a properly terminated line presents a constant pure resistance to a varying input frequency.

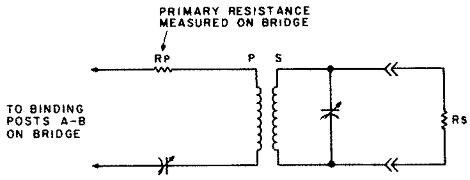

Fig. 4. The effect of secondary resistance being reflected in primary circuit.

Reflected resistance of tuned coupled circuits:

Although it is possible to wade through a great deal of circuit theory to prove that resistance can be reflected from one circuit to another, this easily performed experiment will show it in a manner in which, if once performed, it will never be forgotten. An actual experiment is such a wonderful way of firming up any theoretical proof in anyone's mind. The principle of reflected resistance can be demonstrated as shown in Fig. 4, where a parallel-tuned circuit is inductively coupled to a series circuit. Loading down the secondary with a resistance generates a reflected resistance in the primary whose value can be determined by measuring the change of resistance with the bridge. Close-coupling effects can also be demonstrated by observing the re-tuning necessary to reestablish resonance when the secondary is coupled into the primary. This item described is an easy way to demonstrate rather complex principles, particularly when teaching basics to students studying for an amateur license.

The transistor amplifier:

In addition to the many uses just described, I found that the addition of an SPDT switch, S2, and a couple of binding posts, C and D, would allow me to use the transistor amplifier for other duties in my amateur station. One valuable use is as a field-strength-meter amplifier. My regular simple field-strength meter diode circuit is now far more sensitive, which allows me to make my field-strength measurements further away from the antenna and avoid close-field effects. This makes my field-strength measurements more accurate and meaningful. A second use is as a small experimental capacity bridge, which I built using the same principles as the bridge previously described.

Conclusion

The development of this bridge and an investigation into its many uses has been one of the most interesting projects I've done since becoming an amateur more than fifty years ago. Undoubtedly, many more uses will be found for it, which will further enhance its value in your station. And if you are like me, you'll find that actually building something and using it is a wonderful way to impress theory on your mind. There is no better way of learning than by actually doing. ■

Try the Potted J

—a 2m antenna impervious to the elements

Structural integrity and simple construction.

Some antenna is better than no antenna at all. In many circumstances where adverse weather conditions are encountered, a primary consideration should be to have an antenna that will function dependably even though it might not provide the last dB of gain. This article describes such an antenna designed primarily for 2 meter repeater usage. The antenna has only a modest amount of gain over a simple ground-plane antenna. But, it has far better structural integrity. The materials used to construct the antenna might vary a bit depending on what is available locally, but the design permits construction by anyone using only simple hand tools.

The antenna form is a commonly used variation of the old-fashioned J antenna shown in Fig. 1(a). The variation, as shown in Fig. 1(b), simply uses a closed metal cylinder for the lower ¼λ section instead of the open-style construction of the original J antenna. This type of construction has a number of advantages, such as easy mounting on any type of mast, relatively inconspicuous appearance, and an all-metal, dc grounded structure. Since the antenna's central element and the metal cylinder are electrically shorted at the base of the antenna, that point will be a low impedance point. At the other end of the ¼λ cylinder, there will be a high impedance point. The latter is the only point where consideration has to be given to proper insulation between the metal elements of the antenna.

The mechanical dimensions of the antenna are given in Fig. 2(a). Depending on the materials available locally, the *diameters* of the cylinder and the radiating element can vary a bit from those shown. But, the *lengths* should be closely maintained and dimensioned using the formulas shown in Fig. 1(a) for the particular segment of the 2 meter band of interest. The mechanical construction can vary a bit from that shown as long as the dimensions are maintained, the central element is securely grounded to the bottom of the ¼λ cylinder, and the coaxial feedline is connected properly.

In the method of construction shown, the end of the central element is flattened out at the bottom and bent and bolted to the bottom side of the ¼λ cylinder. Additionally, a small piece of the same material as the central element is flattened out and used as a brace to the other bottom side of the cylinder. The coaxial cable shield is connected via a ground lug to the inside of the cylinder and the inner conductor is either soldered or connected to the central element

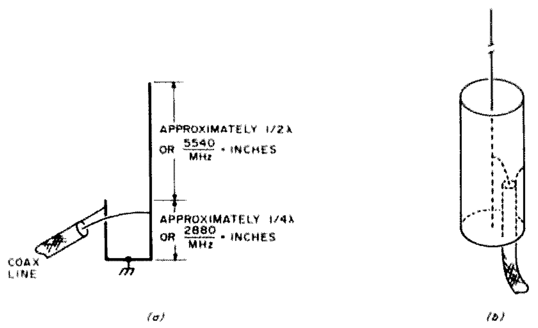

Fig. 1. Basic J antenna (a) and variation where lower ¼λ section is in the form of a cylinder (b).

at the point indicated via a ground lug. The connection to the central element can be made before that element is inserted in the cylinder. The connection of the cable shield must be made after insertion. This requires a bit of dexterity working in the narrow cylinder, but with good lighting and patience it can be done. One handy way to help things along is to temporarily glue the nut for the bolt holding the ground lug on a thin piece of wood. Once the nut is started on the bolt, the wood piece can be broken away.

Before the final assembly step, check the electrical performance of the antenna for swr. It should check out with a very low swr if proper dimensions have been maintained. If one wants to optimize the swr, the feedpoint on the central element can be varied slightly up or down. Usually this can be done without having to change the connection point for the ground shield of the coaxial feedline. This does mean going through the procedure of having to take out and reinsert the central element, but it is not at all that tedious after one does it once or twice. During this test, the central element can be held centered in the upper end of the cylinder by a PVC reducer fitting as shown in Fig. 2(b). These reducer fittings can be found wherever PVC piping fittings are available and one can be found which will fit exactly over a pipe having a 1¼" outside diameter.

The final and most important step in assembly is to fill the cylinder in completely with an insulating compound. This will give the antenna its final mechanical rigidity and, more importantly, completely exclude moisture leakage or condensation in the cylinder. Many potting or sealing compounds can be used as long as they contain no form of metal filler. The plastic resin body fillers sold in automotive stores, with or without fiberglass reinforcement, are readily available. However, to make the filler flow readily in the cylinder, the filler should be heated so that it is fairly liquid. Don't use an open flame to make the filler liquid, but rather insert the container (a tin can will do) containing the filler into a bath of very hot water. Temporarily plug the top end of the PVC fitting where the central element protrudes and, with the cylinder initially held at an angle, pour in the filler from the coaxial cable end.

The use of a coaxial connector on the antenna was deliberately avoided. Simple coaxial connectors, when used in a harsh outdoor environment, will almost always eventually become the source of a problem. This is the same reason why screw-in elements, etc., are avoided. Of course, this all means that the antenna becomes a throw-away unit in case something should really damage it. But, the cost of materials involved to build another antenna is relatively low. As long as it does last, one can use the antenna with the confidence that none of the electrical or mechanical connections inside the antenna are likely to become corroded.

The ¼ λ cylinder need not be insulated from a metal mast as long as it is fastened to the mast at the *bottom* of the cylinder with the usual metal U-type mast clamps.

One can add parasitic or phased elements around the basic antenna if it is desired to obtain some directivity. Parasitic elements, of course, require no cable connection to the main element, but then one has to go through a careful process of seeing that the feedpoint of the main element is altered to compensate for the presence of the parasitic element. In spite of the increased cable cost, etc., if one really wants to keep the weather-ruggedness for a directive antenna installation paramount, it would be better to have two spaced antennas of the type described with separate feedlines. Then, the necessary phasing, matching, and switching can be done from the protected environment inside the shack. ■

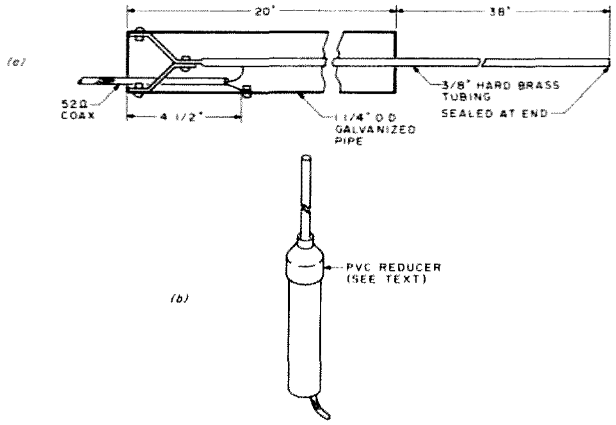

Fig. 2. (a) A cross-sectional view of the antenna giving dimensions centered in the 2 meter band. (b) A PVC pipe reducer used to insulate and center the vertical radiator at the top of the ¼ λ cylinder.

Testing the DSI 3600A Frequency Counter

—as much accuracy as you'll ever need

Score another one for DSI!

Bill Pasternak WA6ITF
Associate Editor

"Measures frequencies to 600 MHz; includes oven-compensated crystal timebase; includes built-in 600 MHz prescaler . . . not an ad-on; resolution to 1 Hz direct and 10 Hz prescaled; sensitivity 10 mV rms @ 146 and 220 MHz to 50 mV rms @ 450 MHz; accuracy .5 PPM over temperature; automatic decimal point placement; 8 large bright .5-inch digits and more!" . . . Yes, these are nice claims for any piece of equipment, and, when you realize that this counter costs only $199.95, it all seems even sweeter. Ah, but there is always a "but." In this case, the "but" was, "but will it work the way DSI claims under actual amateur shack conditions?" The answer is a large-sized "yes," so, if you are interested in a frequency counter of your very own, read on.

When DSI says that the counter comes complete and ready to operate, they are not fooling. Packed along with the 3600A, in the neat little white shipping carton, one will find a 110-V ac to 12-V dc power converter, a telescoping whip antenna, and one of the finest instruction manuals I have seen in a long time. The book not only contains the "how to's" of using the 3600A, but also has detailed schematics that take up two full pages and are very easy to read. Should you find it necessary to perform service on this instrument, such schematics are a true asset.

The basic counter is housed in a scratch-resistant, highly durable black plastic case. Plastic, you say . . . why plastic? Light weight and portability are but two of the reasons and I'll bet there are many others. The fact is that the 3600A is so light in weight that it feels like you are carrying a portable transistor radio without the batteries. DSI claims that there are virtually no spurious emissions from the case, and I corroborated that using my old standby Millen gdo as an absorption wavemeter. Nothing could be detected on the Millen from the BC band through the highest frequency of the gdo. Score one for DSI.

The front of the counter is a transparent dark red panel which has high light transfer properties, and about the only place you may have problems reading the .5"-LEDs is in direct bright sunlight. Along with the 8-digit display for frequency readout there are two other LEDs. One indicates gating time, while the other monitors the cycling of the crystal oven. The base frequency oscillator is temperature-compensated using the time-proven crystal oven technique, and I suspect that it's this oven that accounts for the remarkable long-term stability of the unit. Score another one for DSI.

There is but one control on the counter, and that is its "gating switch," which selects one of two timebases in either the direct or prescaled ranges. The rear of the unit has three connectors. A mini phone jack serves as power input, and two SO-239 UHF connectors are used for both rf inputs. To use the counters, one need only plug the power converter into the unit, connect either an input probe or the telescoping antenna, set range/gating, and read frequency.

DSI includes a warning in their manual that reads in bold black letters, "Warning—do not transmit directly into counter." Actually, the counter seems so sensitive that, in most cases, the whip sup-

plied by DSI is more than sufficient.

To check a frequency counter, one needs a source of signals to read, as well as something to compare against. Well, what can the "average" amateur use as a standard of comparison? In my case, I happened to have tweaked my Clegg FM-76 220 MHz radio earlier in the week on a multi-kilobuck counting device. Since it had only been a few days, I figured that it was close enough for "amateur work." The 3600A showed that the FM-76 was within 50 to 100 Hz on each of its 11 crystalled-up transmit positions. In my book, that was enough proof of the accuracy claim—far more than is necessary for most amateur applications. "Real nice," I thought to myself.

Over the next week, I tried the counter under a number of different conditions. In each case, I was all but amazed by the extreme sensitivity of the unit. One experiment I tried was placing the 3600A atop the Sylvania color TV set in the living room and keying my FMH in the den some sixteen feet away. The display lit up to read 146.52053. Not bad for a 1.5-Watt handheld and a rubber duck to a counter with a whip as an input probe. This "sensitivity feature" was real handy when I decided to reset the transmitter in my trunk-mount Motorola. I simply made up a cable with a mini phone plug on one end and a cigar lighter plug on the other, shoved the 3600A on the rear deck of the Torino to shield it from direct sunlight and tweaked the T-power with ease. No extension cords were needed. The car powered both the radio and the counter.

DSI claims a 600-MHz top end for the 3600A. I can't tell you about that, but it does work to specs in the 440-MHz range as checked using a Motorola HT-220 belonging to a good friend who owns one of those "secret" California remotes. Again, the test was from the den to the living room, whip to whip. I also checked the lower limits of the 3600A by using an Audiovox CB radio and my Globe Scout/Hallicrafters HA-5 combo. I'll tell you one thing—that HA-5 is one stable vfo, even when multiplied to six and 10 meters. I always suspected this to be the case, but having a counter really proved this once and for all. Again, these were the same kind of tests you might use a counter for.

In all, I tried the counter from the 80 meter amateur band up to 450 MHz which were the limits of the test rf available to me. In each case, the 3600A lived up to the claims made for it by DSI in their advertisements. What more is there? If something proves to be as it's claimed, it's very nice to be able to recommend it to others. The DSI 3600A counter is such an instrument.

More information on the complete line of DSI instruments can be had by writing DSI, 7914 Ronson Road #G, San Diego CA 92111. Or, if, after reading this, you are in a hurry to order one, you can call DSI at (800)-854-2049. In California, call (714)-565-8402 collect. Oh yes, lest we forget, DSI gives a warranty of one full year on parts and labor. DSI also pays the return postage. This guarantee is personally backed by DSI's marketing vice president Dennis Romack WA6OYI. I know Dennis and he is the one guy who means every word he says. ■

The Tri-Polarized VHC Antenna

—should be a killer for VHF

Vertical, horizontal, circular.

D. Mitchell K8UR
13356 Wabash
Milan MI 48160

This article is about an easy way to achieve the various modes of polarization from a single antenna system, the VHC antenna. VHC—V for vertical, H for horizontal, and C for circular.

The attempts of antennas in amateur use to achieve the different modes were either expensive (multiple arrays and multiple dollars) or exclusive to a particular mode. This ultimately resulted in the purchase of many identical antennas to hang off the tower for vertical, horizontal, or a combination of the two to achieve circular polarization.

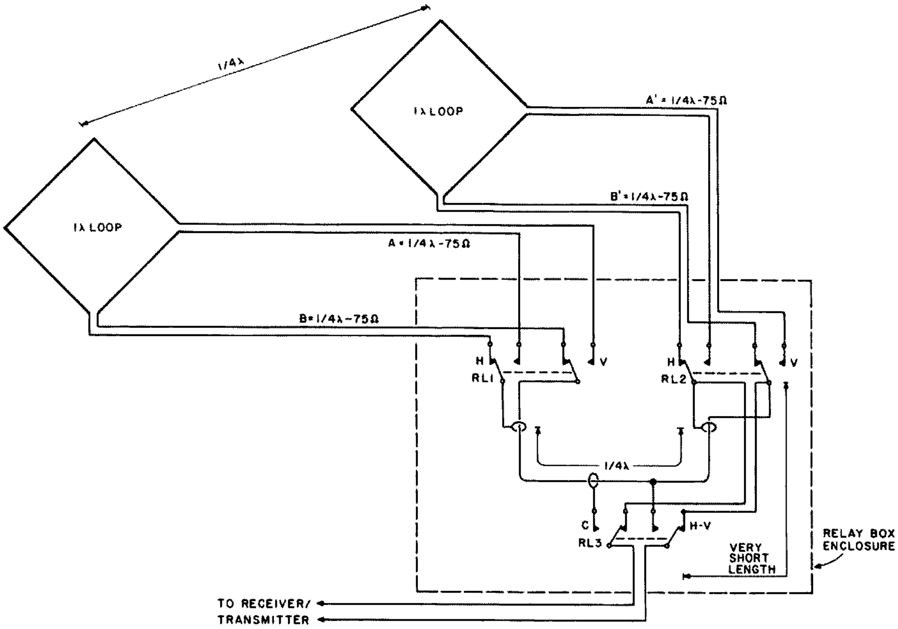

Fig. 1. VHC antenna.

The antenna I am about to describe is a single antenna to be used for all modes of polarization—vertical, horizontal, and circular. All of these polarizations are becoming more common due to the amateurs' diverse interests: VHF-FM, SSB, and OSCAR. Why use one array for FM, another for SSB, and another yet for OSCAR when on the VHF bands?

The VHC antenna idea came to mind while I was operating on 80 meters, actually. I often found it advisable to use a particular mode of polarization for DX work there which was dependent upon conditions on a particular night or even the particular part of the opening. Vertical

polarization proved superior on some occasions, while horizontal polarization would prove better on others.

While the problems encountered on 80 meters may not be thought of in the same light for the VHF frequencies, it is still useful insight, as the VHC antenna did first come from thinking of 80 meter antennas.

The difference between the 80 meter and VHF philosophy is that, on 80, it is not the actual polarization that is important, but the angle of transmitted or received radiation. It is often found that a low angle of radiation on 80 makes for a good DX antenna, but there are times when a horizontal antenna outperforms the low-angle vertical antennas that are often used. The many variations in antenna height and radiation angles of antennas, mixed with the ionosphere height, distance to the DX station, and his antenna system, are too complex for the human mind, and I will not attempt to share my ignorance of the matter with you. But I will tell you of an antenna to try.

The 80 meter version of the VHC antenna appears in Fig. 1. The basic premise is that by feeding the loop antenna at the bottom or top, horizontal polarization results. By feeding the loop at either side, vertical polarization results. And, as stated earlier, I feel it is not the polarization that counts here, but rather the lower angle of radiation achieved by the vertical polarization.

The orientation of the full-wave loop can be either square or diamond or circular. The version that is in use at K8UR is of the diamond variety so that only one support is required.

The idea of the 1/4-wave sections marked A and B is as follows. When feeding A, B (being an open-ended ¼ wavelength) appears shorted at the antenna connection and does not come into play. When feeding B, the ¼ wavelength of A does not come into play. Both elements are identical and the only thing that must be emphasized is that when either A or B length is left unconnected directly to the feedline, neither side of the coax center conductor or shield should be attached to the switchbox in any way. DPDT relays are highly recommended so that the builder does not have problems with the end of the ¼-wave sections of A and B not appearing as a short at the antenna end.

The switchbox containing the DPDT relays should have the SO-239s insulated from the container and tower, if mounted on one. Regular 4-lead rotor cable is used at K8UR to supply the switching voltages to the relays.

A logical way to switch the correct combination of antenna elements into play is shown in Fig. 2. The switching matrix uses diodes large enough for the relays chosen. The diodes can be mounted on the back of the relay voltage select switch that most likely will be in the power supply for the relays, convenient to the operating position.

All lengths of coax used are ¼-wavelength, with the exception being the length between RL1 and RL2, where it is actually two 1/8-wave pieces intersecting at RL3 and connected to RL3. When installing the loops, care must be taken to keep the center conductors of A and A′ going to the same side of their loops, respectively. The same is true for B and B′. If you follow Fig. 1 carefully, you should come out OK. The length of coax from

	RL1	RL2	RL3
Vertical polarization	On	On	Off
Horizontal polarization	Off	Off	Off
Right-hand circular	Off	On	On
Left-hand circular	On	Off	On

Fig. 2. Relays.

the antenna relay box to the transmitter is of any length.

The ability to switch instantly from vertical to horizontal or circular has taken the guesswork out of which antenna or polarization is best at any particular moment. The antenna used on 80 meters does not include the circular feature, but it is worth the effort with vertical and horizontal modes alone.

Two meters should be the ideal frequency for the VHC antenna, with SSB using horizontal, FM using vertical, and OSCAR using circular. The addition of parasitic directors and reflectors also has possibilities for the VHC. For the 80 meter band, where two elements alone are already large, it can be easily made to reverse directions by feeding RL1 first instead of RL2, as shown in Fig. 1.■

The One-Note Pipe Organ

—CW never sounded sweeter

The latest from Rathole 857.

It is springtime. Today is the sixth of May, 1978. It is snowing outside and it is Saturday. So, why am I pushing typewriter keys instead of pushing a straight key down and pulling it back up? Because the spring winds blew all day yesterday, and besides wrecking the chicken house and blowing down branches and trees, it also blew down my entire antenna farm and broke up all the wooden slabs and scraps that held all those wires up in the air.

Mr. Hawkins runs a sawmill just a couple of miles down the road and he lets me have all the slabs and scraps I want. I have burned many tons of them in my heater, besides building the woodshed, the chicken house, and the antenna supports. But, it's snowing, and I don't really want to go scrounge slabs in a snowstorm. So, that's why I'm writing about radio instead of doing radio.

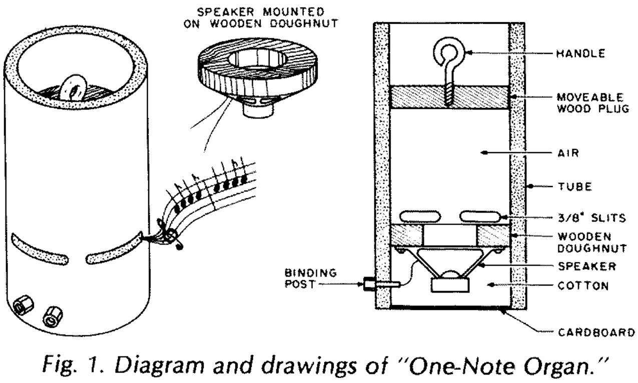

Fig. 1. Diagram and drawings of "One-Note Organ."

A few days ago, I noticed an ad for a special speaker for CW. It shapes the tones or muffles the off frequencies or something like that—there is even a graph full of decibels to show what it does. Aha! A really new idea. There *is* "something new under the sun."[1] Nobody ever thought of this before. Maybe I'll buy one of these instead of an active audio filter.

Browsing in my pile of old radio magazines . . . (Don't get the idea I got all these magazines by subscription. I just recently got my ticket and more recently began to subscribe to *73*. I got most of them at hamfests and from the Lockheed Radio Club for 20¢ apiece.[2])

Well, well. Lookie here! Here's something along the same line, and twenty-six years earlier! (*QST*, Sept., '52, p. 66.) The half page of text gives two versions of a sort of one-note pipe organ, attributed to the R.S.G.B.[3]

I have a Tech ticket (WB7CMZ) but my house is behind a hill and under the power lines, so I cannot key up the "local" repeater (fifty miles away). All I really have is a sort of five-year Novice license. (These days, I could've gotten that[4] anyway, without losing a day's wages and traveling five hundred miles to get it, but that was the best I could do this past winter.) "See Double You" is all I get to do. My antique Hallicrafters SX-28 is not really selective enough to suit me. The device interested me, so I built my own version of it. Here's how (dimensions are not critical, and there are probably 347 different ways to build this gadget successfully):

First, cut two round plugs of wood a little bigger than the inside of the mailing tube. Trim them with a very sharp knife or a rasp until they just fit inside the tube, but won't move without being pushed.

Mount the eyebolt or other handle in the center of one plug, so you can slide it in and out of the tube. You may tune the "organ" by changing the length of the resonant column of air.

Make a two-inch hole in the middle of the other plug and mount the speaker on it. Now is a good time to solder the wires onto your speaker. It will be very inconvenient later. This is the voice of experience. Glue this assembly three inches into one end of the tube. See Fig. 1. Mount the binding posts in the tube wall and solder the wires in place. Fill up the space behind the speaker with the cotton. Don't stuff it in so tight that the speaker cone cannot vibrate. Glue the cardboard circle into the end of the tube so the cotton stays in.

Cut three or four slits 3/8" wide around most of the circumference of the tube just ahead of the speaker plug, so the sound can come out.

Slather plenty of glue on all the cut edges of the cardboard to reinforce it.

Push the movable plug into the open end of the tube. Hook the binding posts up to your receiver speaker terminals with flexible wire. Adjust the movable plug to resonate the speaker to the CW note you like best, or to the note your receiver produces loudest, and enjoy a purer cleaner note, with less buzz, hum, pop, grind, and QRM. And you did it almost for free, in one evening.[5] ■

Parts List

Wooden fruit-lug end (or equivalent)
4"-diameter cardboard mailing tube (or equivalent)
3" speaker (or equivalent)—one that will fit inside the mailing tube
Handful of cotton (or equivalent)
4" circle of corrugated cardboard (or equivalent)
2 binding posts—optional
Hookup wire
Eye-bolt, screw-eye, or other finger handle

References

1. Ecclesiastes 1:9 and 10.
2. 2814 Empire Avenue, Burbank CA 91514.
3. Radio Society of Great Britain.
4. Recent FCC change makes Novice license renewable.
5. Unless you used epoxy glue. It hardens overnight.

Other Notes

1. If you don't happen to have a mailing tube, I suppose you could use plastic or metal pipe, tin cans, or a square wooden tube.

2. If you don't have a speaker that fits inside your tube, put the speaker in a separate box 3/8" away from the tube. If you're a sharp tinkerer, you can think of a way to make do with what you have.

3. If you don't like the looks of it when you get finished, it will work just as well painted, wallpapered, or with a lampshade.

4. I took a picture of this thing, but it just looks like two feet of mailing tube with slits and binding posts. (You can cut it shorter if you don't like low notes.)

5. If you pull out the plug entirely, the whole thing turns back into just a funny-looking speaker for listening to SSB or AM.

6. If you don't have binding posts, send me a quarter and an SASE to Glenn's Trading Post, Rathole 857, Poverty Flat, Eagar AZ 85925. I'll send you a pair you'll like.

A Better Heathkit "Cantenna"

—improved metering circuit for an old standby

Update your dummy load.

The Heathkit® "Cantenna" dummy load, Model HN-31, consists of a fifty-Ohm dummy load resistor, R1, immersed in oil, and an indicating circuit consisting of resistors R2 and R3, capacitor C1, and diode D1. Fig. 1 shows the schematic diagram.

The indicating circuit provides for connection of a direct current meter to the jack marked DC OUT. This arrangement provides a means of indicating relative power.

With the circuit shown in Fig. 1, an amount of power at 3.5 MHz applied to the dummy load will produce a certain meter deflection. If the same amount of power is applied to the dummy load at 29.7 MHz, the meter deflection will be considerably greater.

By modifying the indicator circuit to that shown in Fig. 2, the indicating meter can be made to read the same value for a given amount of power whether it be at 3.5 MHz, 29.7 MHz, or at any frequency between these values.

When this has been accomplished, the indicating meter may be calibrated in Watts and will provide satisfactory indication of transmitter output power at any frequency between 3.5 MHz and 29.7 MHz.

The basic difference between the indicator circuits shown in Fig. 1 and Fig. 2 is that the circuit shown in Fig. 2 incorporates a frequency-compensating network.

In my case, an indicating meter that would read 200 Watts full scale was desired.

The first operation was to modify the circuit shown in Fig. 1 to that shown in Fig. 2. Note that in Fig. 2 the value of resistor R3 has been changed from 1000 Ohms to 2500 Ohms. It will be noted that Fig. 2 includes the additional components noted in Table 1.

All of these additional components are installed within the small metal box which is attached to the pail lid of the Heathkit® "Cantenna."

The indicating meter employed had a 200-microampere full-scale movement with an internal resistance of twelve hundred Ohms. This meter was di-

C2	1.5-7.0-pF glass, piston-type variable capacitor
C3	.01-uF disk ceramic capacitor
R4	1000-Ohm miniature micro-potentiometer, Bourns trimpot 120-14-E1000
R5	1200-Ohm, ¼-Watt resistor, 10% tolerance
C4	4.7-pF disk ceramic capacitor

Table 1. The additional components included in Fig. 2.

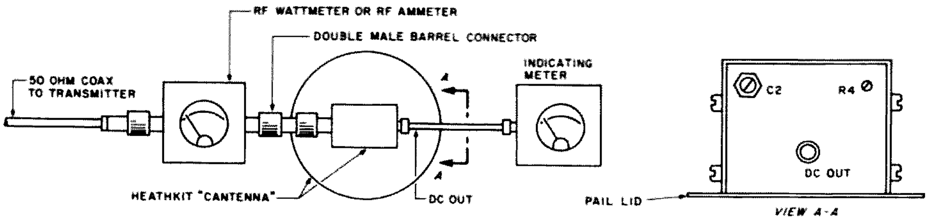

Fig. 3. Setup for frequency-compensation adjustment.

rectly connected to the DC OUT jack of the Heathkit® dummy load.

An indicator that will show the amount of power applied to the dummy load is necessary for proper adjustment of the frequency-compensating network. Either an ammeter or a wattmeter of known accuracy may be employed. The setup for frequency adjustment for proper compensation is shown in Fig. 3.

The adjustment procedure is as follows:

1. Set C2 at minimum capacity and set R4 at maximum resistance.

2. Set the transmitter on 3.5 MHz. Gradually increase the power level until the ammeter reads two Amperes or the wattmeter reads 200 Watts. Decrease the resistance of R4 until the indicating meter reads full scale.

3. Set the transmitter on 29.7 MHz. Gradually increase the power level until the ammeter reads two Amperes or the wattmeter reads 200 Watts. Note that the indicating meter will read full scale before the ammeter reads two Amperes or the wattmeter reads 200 Watts. Reduce the reading of the indicating meter by increasing the capacity of C2 until the indicating meter reads full scale when either the ammeter reads two Amperes or the wattmeter reads 200 Watts.

4. Repeat steps 2 and 3 in sequence until the indicating meter reads full scale when the ammeter reads two Amperes or the wattmeter reads 200 Watts, whether the applied frequency is 3.5 MHz or 29.7 MHz.

If a wattmeter was employed in the adjustment setup, the indicating meter may be directly calibrated from the wattmeter readings.

If an ammeter was employed in the adjustment setup, the Watts corresponding to the ammeter reading are shown in Table 2, and the indicating meter may be calibrated from this data.■

The 80 Meter Coax L

—compact design really works

There have been many articles written about do-it-yourself antennas for just about every purpose imaginable—multi-band, longwires, verticals, big ones, small ones, and on and on, but all of these antenna articles have this in common: You must have certain hardware items available and some electronics expertise to put them together. The antenna I am about to describe to you is simple, small (for cramped spaces), and very efficient. The best part about this antenna is the fact that all you need to build it is some solder, a soldering iron, #14 copper wire, some common hand tools, and a roll of coaxial cable.

I am not an electronics engineer by any stretch of the imagination and I don't fully understand how this antenna works, but I can honestly say that it does work and works very well. I am presently in West Germany with the US Air Force, and I have worked stations all along the east coast and in central USA, and, of course, all around Europe. I received consistent 5/6 and 5/7 reports from all contacts.

Construction and initial testing were conducted while I was stationed in Oklahoma, knowing that when I arrived in Germany, with its narrow, crowded streets and houses touching each other, I would not be able to put up a full-sized 80 meter dipole. This antenna is basically a quarter-wave shorted stub of RG-58 (or other common coax) fed out of phase against earth ground with the outer braid of the coax acting as the radiating portion of the antenna. Better results can be obtained by using a counterpoise or a radial system consisting of one or more radials laid along the ground. If a matchbox is available, this antenna, as described, will work well on 80 and 40 meters without pruning the antenna. It also can be used on other bands by making the length of the coax ¼ wavelength for the band desired. If no matchbox is available, quite a bit of cut-and-try work is required. However, when you reach optimum resonance using this method, the antenna will show an swr of about 1:1 across the entire 80 meter band from 3500 to 4000 kHz.

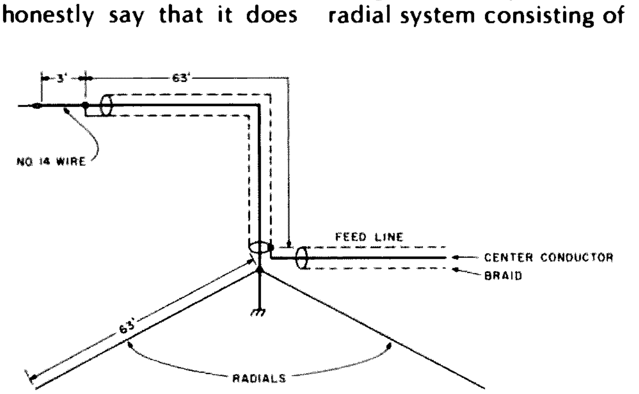

Fig. 1. The 80 meter coax inverted L.

Well, so much for the background history and specifications, and on to the construction and ways to get it in the air.

Construction is started by simply cutting a quarter wavelength of coax (approximately 63 feet) and stripping one end back one inch. Short the braid and center conductor together, attach a three-foot piece of copper wire (#14) to the braid and center conductor connection, and solder. The #14 wire will be used to tune the antenna. Strip the other end of the coax back one inch also and maintain the separation between the braid and center conductor.

When you reach this point, it is time to prepare the feedline. The length of the feedline is not critical and can be made to meet individual requirements. Strip the feedline (opposite the transmitter connector) back one inch and maintain the separation between the center conductor and braid.

Now it's time to connect the feedline to the antenna. This is achieved by connecting the braid of the feedline to the center conductor of the antenna and the center conductor of the feedline to the braid of the antenna. Next, drive a ground rod into good old Mother Earth and attach 1 or 2 radials (¼ wavelength of #14 copper wire each) to the ground rod, leaving the remaining portion of each radial stretched out across the ground. Now, connect the feedline braid and antenna center conductor to the grounding system and solder and tape all connections. The antenna itself can be erected in many ways, depending on available space, as depicted in the illustrations. Select the method that best suits your individual requirements and erect the antenna. It should be noted that the vertical and horizontal distances are not critical, but the connection between the feedline and antenna always should be kept at ground level. After

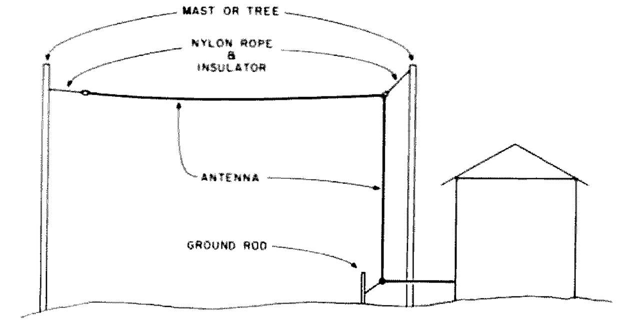

Fig. 2. Hanging method A—inverted L. This method requires only 33′ of yard space. The antenna is raised to a vertical height of 30′, using a tree or mast to secure the antenna to, and then out horizontally a distance of 33′. This method also provides vertical and horizontal polarization.

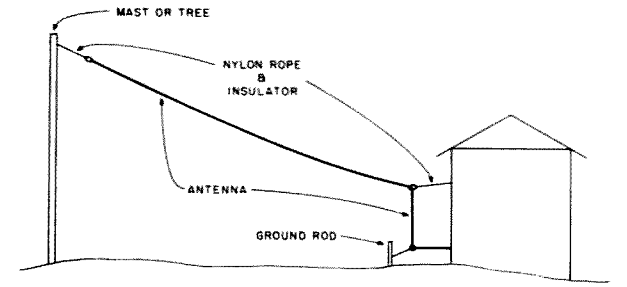

Fig. 3. Hanging method B—sloper. This method requires about 60′ of yard space, but can be used if a tree or mast near the house cannot be utilized.

the antenna has been erected, connect the feedline to the transmitter through the swr bridge.

Start out testing the antenna with low power and remain on low power throughout the testing and tuning stage. You may start with an swr as high as 2.5:1, but don't despair. This is when the tuning starts. Tuning is accomplished by trimming the #14 wire at the end of the antenna. Cut a 6-inch piece of the #14 wire from the end of the antenna and then check the swr again. If the swr has dropped, but not enough, cut off another 6-inch piece of wire, check the swr again, and repeat this process until the swr is satisfactory. If you continue to trim the #14 wire to a point where there is no more wire to trim and the swr is still too high, you must start cutting off 6-inch pieces of the antenna itself. Be sure that the braid and center conductor of the antenna are reconnected each time this is done, before the swr check is made. If, on the other hand, the swr went up after the first piece of wire was cut off, you must add #14 wire to the end of the antenna in 6-inch pieces until the swr is satisfactory. A lot of time could be saved in this process if a friend could cut and prune the antenna while you remain in the shack to conduct the swr checks, shouting instructions to him.

As I said before, this antenna is very simple, small, and efficient, and an excellent one especially for the Novice because of the low cost and ease of construction. ■

OSCAR Orbits

Courtesy of AMSAT

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

New Products

from page 24

order: (1) With too-high selectivity set in, the filter may "ring," so go easy and only use the degree of selectivity you need. Also, remember that it's hard to tune your receiver with 40-Hz bandwidth set in! (2) The auxiliary filter is wired in series with the main filter, so you have to remember to set it at minimum settings when it's not in use. (3) The filter can't completely overcome poor receiver i-f selectivity or overloading on strong signals. You may be able to minimize overload problems by turning off the agc and riding the rf gain control on your set.

All things considered, the filter is undoubtedly a good buy and has a number of very convenient features built in; I enjoyed reviewing and using it. Nevertheless, a few minor improvements could be made: (1) The power adapter furnished with my unit didn't enable the filter to develop quite enough audio. The instructions say that a full 18 volts at 300 mA is required for full two-Watt audio output. A huskier adapter would be useful. (2) The headphone jack could be transferred to the front panel, and a multiple-position speaker/phones selector switch added. (3) An "on-off" LED panel indicator would be a nice feature, as it's easy to forget to turn the filter off when not in use. (4) A schematic diagram, along with alignment instructions, should be provided for the day when maintenance may be required. (5) There is an audible click heard in the speaker whenever the unit is switched on and off. It's not loud enough to be objectionable, however.

At about $80 at this writing, the MFJ-752 filter packs in a lot of features at a modest price; for $20 less, the Model 751 is available (similar to the 752 but without the auxiliary filter, highpass function, bypass feature, and connections for a second receiver). I found the Signal Enhancer II to be a very competitive, seven-IC design that should be a handy accessory and worthwhile investment for the old-timer and beginner alike. For further information, contact *MFJ Enterprises, Inc., PO Box 494, Mississippi State MS 39762; (800)-647-1800.* Reader Service number M52.

AVANTI'S NEW MOBILE ANTENNA

Avanti Research and Development, Inc., has come up with a new concept in VHF mobile antennas, an antenna that mounts on glass in minutes without tools. No ground plane is required, and there are no holes to drill.

A low-profile, one-inch stainless steel mount holds the whip to the window by a new aerospace adhesive discovery that is 50 inch pounds stronger than a 1/4" × 20 metal bolt. It can be easily removed, though, according to instructions, and is guaranteed by Avanti to hold securely under even abnormal weather conditions and excessive vehicular vibrations.

There are no external electrical connections to corrode, as the coax cable and capacitor box are mounted inside the vehicle. The new AH 151.36 antenna has tested 1 dB stronger than conventional 5/8-wave trunk-mount antennas, according to the manufacturer. It is also claimed to have a more uniform omni pattern than "ground"-plane-type antennas.

Because this unique 1/2-wave design is mounted higher than a trunk-mounted 5/8-wave antenna, it offers a higher effective radiation point well above the roof of the vehicle for maximum performance in all applications. The capacitive coupler forms a highly tuned circuit between the antenna and the radio to assure maximum performance throughout the 2 meter band.

Its full half-wave design is said to provide a radiation pattern that is not directionally influenced by mounting location as are conventional 1/4-wave and 5/8-wave mobile antennas. Typical mounting of 1/4-wave and 5/8-wave ground-plane mobile antennas frequently blocks radiation patterns.

The stainless steel whip and hardware connect to a chrome-plated casting. The tough ABS capacitive coupling box houses a fine-tuning coil connected to the radio by a preassembled coaxial cable assembly. For further information, contact *Avanti Research and Development, Inc., 340 Stewart Avenue, Addison IL 60101; (312)-628-9350.* Reader Service number A93.

Ham Help

I have a Motorola UHF rig, model U44BBT-1000A which I plan to convert to 440 FM. I would like help in obtaining all schematics and information possible on the radio and its conversion. I also need wiring diagrams or schematics for the control head, which is missing.

LETTERS

from page 14

I recorded, on a standard tape cassette, much of their operation. I even caught one net when they switched to high-speed CW. The cassette, along with a detailed log, was sent to the ARRL "Intruder Watch." After a couple of months, with no reply, I sent a letter directly to Dick Baldwin asking if they had received the cassette. Again, no reply. Finally, after a few more months, I asked Harry Dannals to check on this. His verbal report was that they had received it, but apparently lost track of the cassette—they didn't know where it was! So much for "Intruder Watch."

Yes, 40 meters disturbs me, too, like 160 meters disturbs me. Yes, I know, the ARRL is the only "game in town." With all the money they have (our money), why can't they represent us *properly* in Washington and in Geneva? It is no wonder that not all hams are members of the ARRL.

An interesting sidelight: Many Long Island (this is Dannals country) hams, staunch defenders of the ARRL and loud detractors of Wayne Green, do not subscribe to *73* and don't read his editorials elsewhere! Guess who tells the radio clubs in the Hudson Division that Wayne is "lying"?

Thanks again for telling it like it is.

Huntington NY

DOUBLING

In the midst of the confusion generated here in JA/KA land by the FCC's new "system" of assigning amateur callsigns, a dim ray of hope came to me the other day. I'd like your opinion and the opinions of your readers on this.

What about doubling the number in the present KA callsigns in Japan? Instead of KA2RF, why not KA22RF? Instead of KA6OJ, why not KA66OJ? I'm not sure if the authorities here would go along with the idea, but it seems worth a try to me.

As I understand the system here, the FCC doesn't have to agree with such a change. They *don't* make our present callsign assignments.

Would such a change only cause more confusion? Would it make the KAs in Japan a unique, recognizable group again? Has anybody got a better idea? Let's hear from some of the former KAs who have operated from Japan. Let's hear from some of the new KAs in the States!

GFI'S

I enjoyed your June, 1979, issue of *73 Magazine*. Your article on page 138, "Protect Yourself with a GFI," is very true and something all of us should be aware of. I notice, however, that the price schedule on page 140 for the components and what it would take to build this apparatus does conflict quite a bit with available ready-made kits. For example, Hubbell Electric Company has a portable model GRP-115 available which has been on the market for some time. This unit sells complete for $53.60. Likewise, Slater Electric Company has a ground-fault interrupter ($30.60) with the entire component layout built into a receptacle which can be placed in a normal-sized 18-cubic-inch box. The two devices I am mentioning have a reset and test button already built into the receptacle, and, of course, do not need a 6 x 9 box with handles to enclose same.

Such devices have been required in any new construction since January 1, 1975. In other words, thousands and thousands have been produced and installed with very few problems. This could very well be the basis for a future article for your magazine.

CODE FOREVER

I have listened to your voice so much on the *73* Novice code study tape that I feel like I know you. I hope to finish up the Novice test next week and take the General in the next 30 days or so. Please let me thank you for the outstanding study material.

The letter from Jack McCord KA4EXD published in the May, 1979, issue of *73* was most interesting—made me stop and think a little. Here I am at age 42 working on a Novice ham license, looking forward to all of the possible new contacts and friends out there, and wondering why someone of Mr. McCord's radio experience and background would even think thoughts like that, much less write them!

I have sat by the radio for many years just listening, and now I sincerely have to search my soul to try and find just why I never realized what a truly wonderful hobby media amateur radio is. I could kick myself for never taking the trouble to sit down and learn the code that bonds all radio amateurs into a group that is like no other. I hope the code requirement is there always.

During the past few weeks, my understanding of the radio service, the amateur who does the talking or communicating, and the fraternity that this relationship and association really is has been increased with each dah and dit that has entered *my* mind. And believe me, it hasn't been easy. That has probably made it even more worthwhile!

Certainly ham radio has the rag chewers, the QSL collectors, the weather askers, and the guys who do all of the other things that Mr. McCord wrote about. It is a hobby, not a profession, and it is to be enjoyed. With all of the many hams out there, somewhere there is a person who enjoys the same thing you do. This is the reward of ham radio—trying to find this person—and making many, many contacts and friends along the way. I am really looking forward to it! I am just sorry I waited so long to get started.

Since Mr. McCord is a locomotive engineer, maybe his feelings have something to do with going down the same old tracks, in the same old trains, pulling the same old cars, never looking at the different people he is passing on his ride through life. The day will come when he will realize that he is wrong, and if not, I feel sorry for him

Again, thanks very much for your excellent publication and study materials. Although I purchased the ARRL package, too, I found your material and tapes much more valuable with regard to the tests. I am planning to press on for the General, Advanced, and Extra as my knowledge and understanding increase. I will be using your materials to get me there.

I am a Captain with National Airlines, flying the Boeing 727 on routes all over the country. Should you ever fly National, please check "up front" to see if I am there. I would enjoy talking with you.

William D. Mauldin
Boca Raton FL

THE WOODPECKER

I wanted to write you about the letter in May's *73 Magazine* concerning the Russian "woodpecker." I tried the recommended procedure from the shack at the store, and it worked. It may have been coincidence, but soon after I began to send dits in time with the clicks, the interference stopped. Even if it was coincidence (both times), it made me feel better! I hope it is really working, for that damn noise has helped me lose more DX than just about anything. The gentlemen from the West Coast DX Association are to be applauded. Now the Russians are probably hot on UFO chasing, with the recent glitches in their little radar. Brilliant!

One other thing, Wayne. Don't be too hard on those people who are loyal fans of yours. I understand your position on wanting people to agree with you with their brains and not their guts, but you are a public figure—in the public eye. To many, you are bigger than life whether you like it or not. Their gut reactions begin in their brains, for their brains filter your words down to the level of emotion. This is basic human nature, and this is an emotional subject, unfortunately. I think you'd be surprised at how many friends you have that never speak up for themselves; they like to hear you speak for them. I think they would come through in a pinch, however, and their group should be cultivated. You have the rare talent of being controversial combined with the ability to make friends. Well, I don't want to get too far into this, for I don't want you to think I'm a sentimental clod. Just know that you have friends who are behind you.

Steve Baumrucker WD4MKQ
Chapel Hill NC

Thanks for the most kind letter. If you get any more data on the woodpecker, please pass it along!—Wayne.

VLF

I have just had the pleasure of reading Mr. Ralph W. Burhans' article on VLF reception, and would like to inform readers that they can obtain more information from the manual *Naval Shore Electronics Criteria, VLF, LF, and MF Communications Systems*, Navelex No. 0101,113 (Federal Stock No. 008-059-

00015-2, $3.50), available from the Superintendent of Documents, US Government Printing Office, Washington DC 20402.

Chicago IL

IARL

Please count me in as a charter member of the new International Amateur Radio Lobby. I'll join as soon as you call for members! Whatever happens during WARC '79, we all need to be more prepared the next time around. The organization you outlined in the April, 1979, issue of *73* looks as close to ideal as possible. I hope you can get it all together by the end of the year.

In answer to your questions, ten dollars a year is more than fair. With the ARRL asking eighteen dollars a year, you could probably justify twelve to fifteen dollars a year.

Contests have a definite place in amateur radio—how about the special mode contests, i.e., computer CW, RTTY, SSTV, satellite, etc.? Your mentioned contest ideas are very good.

The "IARL" should be separate from *73 Magazine*. I say that because I hate to be forced into anything—the choice should be left to the individual. A package price for the two would be welcomed, I'm sure.

The officers of the organization should be elected by the rank and file members and they should hold a two-year term.

In summary, I think we need a strong lobby voice in Washington, and I have full faith that you can get the job done. Go to it!

Clearwater FL

CANAM COUNCIL

The Canam (Canadian, American) Repeater Council was formed in 1973 on the initiative of the Brandon Amateur Radio Club.

The Council is made up of representatives from amateur radio clubs from Manitoba and North Dakota. It usually gets together twice a year and meets on the air in between. It was our opinion that some group should be formed to suggest frequencies for the use of repeaters on both sides of the border so they would not interfere with each other.

It was hoped that groups planning repeaters would contact the Council before they picked their frequencies to see that it was not likely to interfere with some other group.

We would like to see every club in Manitoba and North Dakota have a representative on the Council.

For further information, please contact: Bill Graham VE4QG, 16 Frontenac Crescent, Shilo, Manitoba, Canada R0K 2A0, or Ken Larsen K0PVG, R.R. #1, Devils Lake ND 58301.

Dave Snydal VE4XN

WARMED OVER?

The April issue of *73* contains comments by Wayne regarding the $100,000 fiasco by the ARRL last year. This is old, old news.

The fiasco was disclosed at the Pacific Division Convention at Reno last August as explanation for the large number of *Handbooks* donated for use as door prizes. I was the recipient of one.

I know Wayne laughs all the way to the bank with his ARRL "disclosures." We look to him to amuse us with new stories, not those that are warmed over.

Vince Salemme
Livermore CA

W2NSD/1
NEVER SAY DIE
editorial by Wayne Green

from page 7

During the much-too-brief planning sessions for the linear amplifier testimony, I tried hard to convince the ham manufacturers and Bob Booth to think along these lines, but there was no way to convince them. They knew that the Commission was dead wrong and they were determined to tell them that. The Commissioners did not want to hear this news, so it went in one ear and out the other.

If we want a Communicator Class license, we can have it. First, we have to find out what the problems are which are holding it up with the Commission . . . and there is no difficulty in getting this information. Next, we have to come up with some good solutions to these problems . . . solutions which will make it beneficial for the FCC to do what we want. If we provide enough benefits to the FCC and don't give them additional problems, we'll get everything we want. It's as simple as that. This is the way I organized the hearing in 1973—and it worked perfectly. It can work again.

BENEFITS

The key to any sales pitch, whether it be for subscriptions to a magazine, to advertisers, to sell a product, or to convince the FCC to act the way we want, lies in the simple concept of emphasizing the benefits and having a ready and simple answer to any objections. For instance, when our ad department talks with advertisers, we point out that our readers are spending an average of $500 each per year on ham gear according to our latest poll. If you work that out, it comes to roughly $3.75 million per month . . . and that comes to about $37.50 in return for every dollar spent in the magazine for advertising. That's one hell of an ad return, and it perhaps explains why *73* has more ads than any other ham magazine. Most advertisers are primarily interested in the bottom line . . . not in a bunch of talk about circulation (which can include thousands of libraries . . . which don't buy products).

With the drop in newcomers to amateur radio, it might be prudent for both the industry and the clubs to think seriously in terms of getting some action on a Communicator Class license . . . there are certainly a bunch of advantages for hams. We've seen what the sparse use of 220 MHz has done to us . . . first with CB trying to poach it and then with the maritime interests sneaking around in back of us and grabbing it via the WARC route. We desperately need new hams, and I think we've seen that the traditional way of getting them has not been working.

WARC

There has been nothing much new on the WARC front . . . still no reason for optimism. But once that is past . . . if we are reasonably intact . . . we will have to get started on a program of growth and modernization. I've written before on our need for a three-pronged approach to the situation . . . with a lobby in Washington to work on getting the rules we need through the FCC expeditiously . . . a national lobby to get news of amateur radio into the media and encourage the growth of the hobby . . . and an international lobby to get amateur radio into every one of the emerging nations and make them supportive of amateur radio at future international conferences.

Let me say this clearly: If the ARRL doesn't shape up and accept the responsibilities outlined above . . . I will do it. I prefer to do more fun things and develop computer software sales . . . perhaps DXpedition a bit, etc. From here on it is up to you . . . either you get the League to stop wasting your money or else I'll get something going to do the job they should be doing. Note that, ARRL directors.

If I do get something working along this line, it is going to cost a lot more than $18 per year and you are going to enthusiastically support it. But then, I will get the job done and not come up with an emerdement of obfuscation about why nothing happened.

APRIL WINNER

Philip S. Rand W1DBM ran away with April's $100 bonus check for his article "An 8-Element, Ail-Driven Vertical Beam." Remember, you can vote for your favorite article by using your Reader Service card ballot at the back of the magazine.

BRITISH HAMFEST

The RSGB was kind enough to arrange their yearly hamfest during my short visit to England in May, bless their hearts. My main purpose for the trip was to set up distribution of Instant Software in the UK and other European countries, but you can be sure that I didn't miss visiting the yearly hamfest.

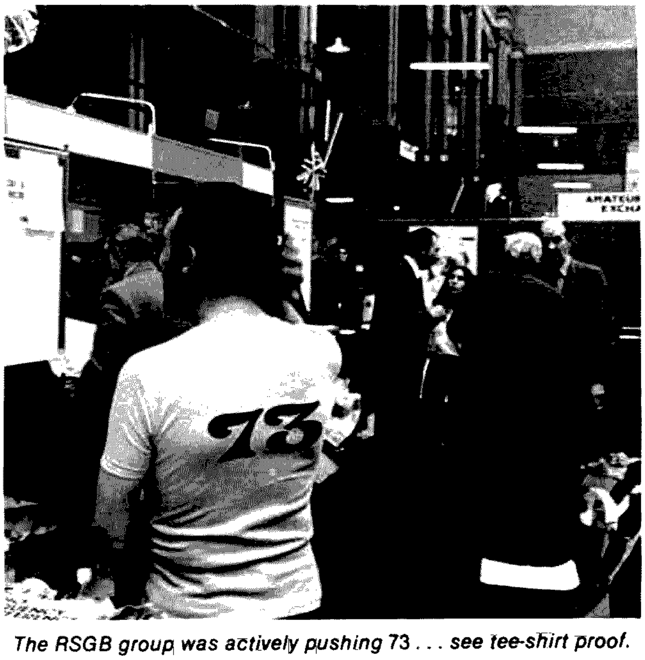
It was quite a way from the center of town. Sherry and I found it at the end of an Underground line . . . plus a bus trip . . . at the Alexandra Palace . . . a large building. My ego got a boost right away when I was recognized by some local *73* readers. That's fun.

I snapped a few pictures so

you could get an idea of the size of the hamfest. It was mostly involved with the selling of equipment and parts. They had dozens of booths selling zillions of radio parts.

This is a wide-angle view showing the center part of the exhibits floor. There is an antenna booth at the lower right and an enormous pile of used test equipment (much of it laboratory) in the center.

On each side of the main hall was a smaller section, again filled with booths selling used equipment and parts. It was perhaps 70% giant flea market in US terms.

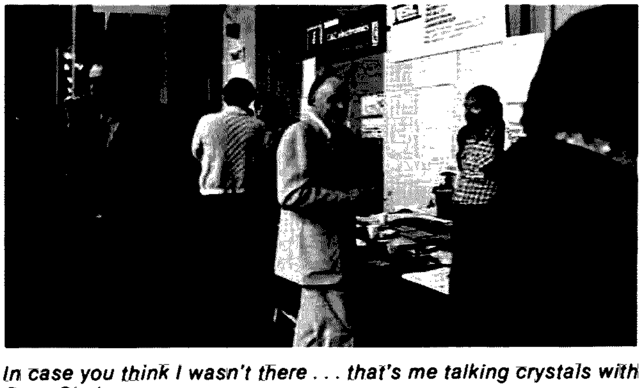


The RSGB group was actively pushing 73 . . . see tee-shirt proof.

This is the front of the palace. The exhibits hall ran the entire length of the building! You had to go way around to the side of the building to get in.

Most of the ham gear was pretty much what we have. It comes from Japan, just like ours.

This view may help give you an idea of the size of the place. This shows just the exhibits in the left-hand side of the main hall.



In case you think I wasn't there . . . that's me talking crystals with QuartSLab.

Microcomputer Interfacing

from page 26

wanted noise generated by the switching transients.

Analog switches may be used in almost any circuit that requires a voltage switch. Typical applications for analog switches include their use in D/A converters, programmable gain amplifiers, filters, and integrators. Our main interest in these switching devices centers around their use in analog multiplexers used to switch multiple signal inputs to a common point for amplification and digitization. The two types of switching devices that we shall consider are those without decoders and those with decoders.

Some analog switches, such as the Texas Instruments TL182C and the Analog Devices 7510, 7511, and 7512 devices, have control inputs for each individual switch. Pin configurations for these chips are shown in Fig. 2. This type of analog switch requires a separate logic signal to actuate each switch. These switches find use in applications where more than one switch is to be actuated at one time, or where individual switch control is needed.

Switches employed for analog signal multiplexing are generally more useful when they are equipped with built-in, or on-chip, decoder circuits. Such decoder circuits typically accept parallel binary TTL input and then actuate the correct switch that corresponds to the binary code applied. The binary code can only represent a single binary value at one time, so only one switch at a time is actuated. Block diagrams and truth tables for the Analog Devices 7506 and 7507 analog multiplexers are shown in Fig. 3.

When using analog multiplexers with on-chip decoders, it is still the user's responsibility to provide the correct code of the channel required. Many decoder chips also contain an enable input that permits multiplexer schemes to be expanded to include a larger number of selectable channels.

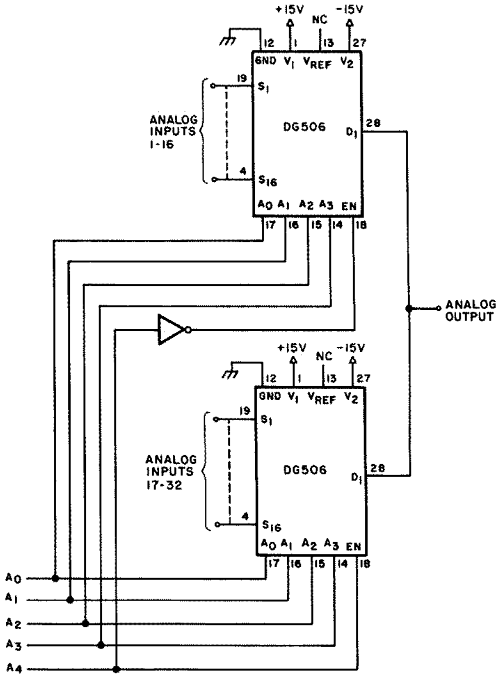


Fig. 4. Block diagram of a 32-channel analog multiplexer using 16-channel multiplexer chips.

A typical example is the 32-channel multiplexer circuit shown in Fig. 4. In this example, a Siliconix DG506 multiplexer is used. Note the use of the enable input at pin 18. This input allows us to switch between the two multiplexers by enabling one while disabling the other. With the aid of such an enable input and additional decoder circuits, such a multiplexer scheme can be expanded almost indefinitely.

Looking West

from page 12

the area. Paul said that with higher antennas, their distress beacon would have been more likely to be heard and rescue could have begun more quickly. It was very effective, since it emphasized in a direct way the sometimes life or death situations which occur and the value of our activities in dealing with them.

The Planning Commission voted to recommend to the Board an amendment excepting amateur antennas up to 100 feet in height from the minor use permit requirement. This was encouraging, but not entirely satisfactory. The Commission reasoned that a 100-foot threshold would exempt nearly all installations.

I did not mention the petitions to the Planning Commission. The Planning Commission is composed of citizens appointed by the Board of Supervisors. Petitions, it seemed to me, are most impressive to elected officials who run for office and who can be expected to be more sensitive to public opinion.

We were encouraged by the Planning Commission action. After all, for our purposes, 100 feet is more than twice as good as 50 feet. Since the Planning Commission action was unanimous and also supported, if somewhat belatedly, by the LUER staff, I was confident that the Board would approve at least 100 feet.

The Board of Supervisors hearing was set for April 29. An intensive effort was made to get a large turnout, since we felt that our turnout of a dozen or so at the Planning Commission hearing was definitely a helpful factor In obtaining the 100-foot recommendation.

About 30 hams appeared at the Board hearing on April 29. We found ourselves near the end of a long agenda. Arrangements had been made, as we had done at the Planning Commission hearing, to announce on the Otay repeater what time we would be heard so that all of us would be spared the ordeal of sitting there all day waiting. As it turned out, we sat there until after 4 pm when the Board realized that they would not get to us. The hearing was continued to May 16, with a promise that we would be heard early on.

We had decided, on the theory that there's no harm in asking, to take the approach that, while we definitely favored an amendment, we would be most in favor of a total exemption, being limited only by FCC rules which allow up to 200 feet in most areas.

We redoubled our efforts to obtain a large turnout, with hams even taking a day off from work to attend. Paul WA6GDC, a most talented artist, had come up with the great idea of inviting local hams to the "county's largest antenna-raising party, at their (Board of Supervisors) place." Paul drew this up and got it circulated and published in several newsletters and posted in all the local ham equipment outlets. This was another terrific example of the extraordinary creativity and willingness to work that many hams displayed.

Our efforts were rewarded by the appearance of about 60 hams at the hearing on May 16. This accounted for about 90% of the total attendance at the hearing, at which several other items were to be considered besides ours.

I had arranged for Bob WA6QQQ, who is a radio engineer and consultant to the broadcast and TV industry with top-notch credentials, to give a short technical presentation. He worked up a number of good points, but the Board indicated they didn't really want to hear the technical side of it. I thought this was a real shame, since he had done a lot of work preparing. His input was very valuable in helping me prepare my remarks, and so his effort was by no means lost, even though he didn't give his presentation.

Don WB6DPO, President of the El Cajon Amateur Radio Club, gave a brief but effective statement on behalf of that club's membership. The club's newsletter editor, Charlie WD6GVR, brought out, in a very impressive way, by asking a question, that the cost of a minor use permit was at least \$450—with no refund if denied. Jim Smith W6VCE gave a short talk emphasizing the value of our emergency services to the Weather Bureau, among others. His remarks drew brief applause.

Supervisor Lucille Moore's late husband was a ham, and she had a very good idea of what we were talking about. Supervisor Roger Hedgecock

surprised many of us by indicating that he felt local government would do well to avoid regulating amateur radio in a manner inconsistent with FCC rules, which, he said, "cover every detail."

Mrs. Moore initially moved acceptance of 100 feet. The vote was a 2 to 2 tie. After further discussion among the Board and several questions about FCC rules to the staff and to me, Mrs. Moore moved acceptance of an exemption of 200 feet. This time the vote was unanimously in favor. Sustained applause and cheering greeted the vote. We had won!

How had it happened? Primarily, I think, we learned that if we "circle the wagons" and all pull together, and if we prepare ourselves to sell our program in a positive, reasonable manner, our chances of success are considerably improved. Ham radio has an excellent record in most places and can be sold. By the way, it seems to me extremely important to preserve and guard this excellent record from being sullied by unfortunate and imprudent conduct.

In our case, three factors seem to account for the success of this effort. First, we had a fairly large turnout at the hearing. We would have been more secure had we had a large turnout at each hearing, but not everyone can arrange his affairs to attend. Hams have to work, travel, etc., just like anyone else. But it was definitely important that the Supervisors could look out into the audience and see that, if nothing else, their action was going to be witnessed by a roomful of voters who were concerned enough to come out and participate, who would probably remember this come the next election, and who were probably interested enough to tell their buddies how they were treated.

Second, the petition had a very important positive effect on the Supervisors. We didn't tell them how many signatures were gathered. I gave the petition to the Clerk of the Board without fanfare at the first hearing, which was continued. The Supervisors had the exact number of signatures at the time of the final hearing. *They* had had a count made by their staff, and when I mentioned the petition, they indicated that they had definitely reacted to it.

Third, we tried to present our arguments in a positive, rational way. This was in contrast to a group which appeared on another matter prior to ours. The thrust of their argument was negative. They eventually berated the Supervisors for passing such "stupid laws and for being such stupid jerks" who couldn't see the justice of the change the group sought. Needless to say, this was very poorly received. They went home empty-handed.

We tried to structure our presentation to emphasize the public interest, balancing the competing diverse interests in aesthetics versus the importance of reliable public service communications. The function of the Board, and any deliberative law-making body, is to balance these competing values, and this seemed to strike a responsive chord.

Special credit for this affair goes to SANDARC delegates and officers, SCM, W6INI, W6GIC, W6SLF, N6LY, W6QR, K6NA, W6US, K6KOI, WA6GDC, W6PDA, WB6DPO, WD6GVR, W6VCE, WA6QQQ, WA6HJJ, the officers of the several radio clubs in the county, and countless hams who pitched in and helped in many ways.

Who says you can't win at City Hall? We did!

•••••

There you have the story from someone who was a part of it. Looking West wishes to add its congratulations for the fine teamwork shown by the San Diego amateur community in stopping this ordinance from becoming a disaster for the Amateur Radio Service. Special thanks to Sybil Albright W6GIC for sending along Jim Allen's fine story.

TWO METERS AND THE GREAT BALLOON RACE

About ten years ago, the famed Fifth Dimension vocal group had a million-plus-selling record titled "Up, Up, and Away!" It was a dream song; it told of sailing freely through the air, free of the earthly bonds that shackle mankind to his oh-so-hum-drum existence. It was a song that any dreamer could relate to. It has stayed with me ever since . . .

There are balloons of one's dreams and then there are the real kind, the ones filled with helium or just hot air (no pun intended) that do indeed lift man from his earthly bonds. The fact is that ballooning is a very big hobby with many today and interest in it grows with each passing year. It was because of this interest that, in the year 1906, an expatriate US publisher named James Gordon Bennett lent his name in sponsorship to what came to be known as the Gordon Bennett International Cup Race. With the exception of the World War I years, the race continued uninterrupted until 1938. Poland won that one. However, then World War II intervened and a cloud of silence fell upon the event from 1939 to 1979.

Things might have stayed this way if not for the intervention of Dr. Tom Heinsheimer. Dr. Heinsheimer is not a ham; he is an aerospace scientist with a sincere love of ballooning, according to Nate Brightman K6OSC, who supplied much of the input for this story. It was because of the unyielding devotion of Dr. Heinsheimer that the year 1979 saw the revival of this event. Herein lies an amateur radio story to capture the imagination of any ham.

The "New Gordon Bennett Race" took a path from Long Beach, California, eastward to the "Duke City" of Albuquerque, New Mexico. It was expected that any balloon completing the race would be airborne for a minimum of 72 to 96 hours. Nobody could really be sure, since gas-filled balloons do not perform in the exact same manner as do other aircraft. You really can't steer a balloon. You can make it go up, you can make it come down, and that's about it. Once airborne, you are strictly at the mercy of Mother Nature herself. You go where the prevailing winds take you and the final outcome is anyone's guess. On the weekend of May 27th, some 18 gas-filled balloons took to the "wild blue yonder," scattered hither and yon as the winds carried them, in hopes of being the first to set down in the "Duke City."

Organizing a race such as this really presents quite a logistics problem, as you can well imagine. How do you keep track of eighteen free-flying balloons that might go anyplace? Enter amateur radio and an organization known as the Associated Radio Amateurs of Long Beach. Since the race was to begin in the parking lot for the *Queen Mary*, now permanently docked in Long Beach, California, harbor, using the newly-restored "wireless room" aboard the *Queen Mary* as a control point seemed to be the logical first step. The FAA must have thought this was a good idea since they declared the "wireless room" a temporary control tower for the duration of the race. The balloons

Thirty-five members of the Associated Radio Amateurs of Long Beach took part in communications handling for the Gordon Bennett International Balloon Race. The ARALB boasts a membership of 225. Photos by Nate Brightman K6OSC.

Ron Boan AK6Y, member of the ARALB, who set up the net with Arizona and New Mexico hams, is shown acting as net control. A minimum of 32 hams maintained a vigil on the net until released by Ron. Nate Brightman K6OSC, Projects Chairman for the ARALB, was Director of Communications for the balloon race.

After nightfall, Howard Brightman K6OSD followed his field operation with a night of monitoring phone calls from the balloon chase crews and the news media. Logging the most number of continuous hours, he slept with the phones and totaled 81 hours of operation. Behind Howard, a member of a chase crew club records reported balloon position. All field HT operators wore green ribbons on their right shoulders for easy identification.

As balloonist Ernest Iseln HB9BJ (one of two hams racing) looks up at his balloon, Howard Brightman K6OSD uses an HT to report progress to the command center in the Queen Mary *wireless room. The other ham racing, pilot of the Japanese balloon, was Saburo Ichiyoshi JR1IHI.*

were ordered to carry portable battery-powered VHF aircraft transceivers; however, there was no way to recharge batteries should they fail. Another sure-fire method to keep track of the balloonists was needed.

Since each balloon would have a chase car following it, it was decided that each car would be supplied with an amateur transceiver and a licensed amateur to operate it. To ensure ongoing communications, a two-meter interlink stretching from Los Angeles to Albuquerque by way of Kingman, Arizona, was established so that those serving as communicators would never be out of contact with the command center aboard the *Queen Mary.* Operators with hand-helds were also solicited and dispersed as lookouts from some of our "natural towers" that abound in the southwest. Under the guidance of the Associated Amateurs of Long Beach, a complete communications network was set up and checked out prior to the race. During the event, it performed flawlessly.

As the balloons took to the air, things reached a fever pitch on 146.52 and remained that way for close to three days. Even though .52 is a heavily used simplex channel around Los Angeles, virtually the entire amateur community stayed clear of the channel for the duration of the event, thus permitting an uninterrupted flow of information among those amateurs involved in the tracking operation. As an added measure of protection, a group known as the "Happy Flyers" was on standby alert should their services be needed. Operating under the direction of Squadron 5 Commander Lee Osborne WA6FSP, the Happy Flyers, who are a group of amateur radio operator pilots who normally involve themselves in search and rescue missions of downed aircraft, would take to the air to locate any balloon that might be lost from ground-level visual contact. Being amateurs themselves, the Happy Flyers could converse directly with both the command center and the ground units, thus eliminating the need for crossband relays. Luckily, nothing in the way of a true emergency occurred; however, for the first few hours of the race, an aircraft piloted by Commander Osborne was in the air to oversee things.

None of the balloons reached Albuquerque. One well-known balloon, the *Double Eagle II*, reached Las Vegas and under the rules was declared the winner. Others did not even get that far. Another US entry named the *Rosie O'Grady* touched down a few short hours later in the parking lot of the Jet Propulsion Laboratory in Pasadena, California, thus taking about five hours to make the trip from Long Beach that can be driven in 40 minutes. However, to balloonists, time has no relevance whatsoever; it's the freedom that counts. "To dance across a silver sky . . . to fly . . . free as a bird." To follow a dream—that's the real meaning. A US entry won this year's Gordon Bennett Race and next year the US will again host the event. Already the Associated Amateurs of Long Beach are planning for it. They did an excellent job this year and they intend to make next year even better.

220: THE WAR TO SAVE IT CONTINUES

The May 25th edition of *HR Report* contained a front-page statement that has angered many Southern California amateurs. It is *HR Report*'s claim that the "Fight to Save 220" campaign initiated by the 220-SMA of Southern California and taken up nationally by other groups is actually hurting the growth of 220. The story states that the current campaign is making people adopt a wait-and-see attitude and that this has stifled growth of the spectrum.

Rationale for this closing statement comes from *HR*'s belief that surface facts concerning the future of this spectrum point to the US position as being one of "bargaining" with 220 as nothing but another pawn in an overall chess game, that in the end, 220 will be safe and therefore this campaign is really not necessary. If only we could be sure that such was the case. However, the bureaucracy has sold amateur radio down the tubes so many times that in this case amateurs are totally convinced that their only defense is a strong offense, that once and for all it is time to put a stop to the "woodpecker effect" that has over the years eroded our spectrum. Every 220 operator I talk with, and that is a goodly number each week, is convinced that this is a fight to the death, that this is the one singular battle that will determine the destiny of all amateur spectrum. If inroads of any type are permitted to take place on 220, then no band is safe. Will 450 be next? Two meters or 20 meters perhaps? Regardless of what *HR Report*, the ARRL, or anyone else says, the battle will continue until such time as one side or the other has fallen. The objective is to once and for all make it clear that amateurs will not permit even the slightest bit of spectrum theft and will not tolerate further threats to 220 or any spectrum now assigned to the amateur service from any quarter.

220 operators from all over the nation have jumped onto the "Save 220" bandwagon, but, as of yet, only one magazine. Neither *QST* nor the ARRL proper has been heard from and everyone else seems to be waiting in the wings for something to happen. The 220 people I have spoken with have made it clear that with or without the blessing of the Newington hierarchy, they will continue. They never expected any real ARRL support from the outset and could care less if it does come. Even ARMA, which has a vested financial interest in this spectrum, has yet to come forth and say yea or nay. In the end, this has become a fight of the "people" against the "establishment," and the only support they have asked has been from one another. By far, the people of 220 are far more "together" than any other group I have ever had the opportunity to witness. Other amateur special interest groups can really take a lesson in strategy planning from them. They have, in effect, placed everything on the line in fighting to protect their spectrum and no veiled promises or threats will dissuade them. They could care less what the establishment thinks. They're out for only one goal—to win!

Along these lines, it was recognized that one of the most important aspects of any campaign is the ability to readily communicate. However, channelized relay operation does not readily lend itself to this without complex intertie systems. In seeking an alternative to this, 220-SMA Advisor Ray Von Neumann K6PUW and Henry Lachmiller WB6JLG hit upon a simple solution. Just as UHF remote bases have established 146.46 MHz as the National Remote Base Intertie Channel, why not have a similar gather-

ing spot for 220-MHz systems? Consultation between the 220-SMA and TASMA led to the establishment of 145.56 MHz as the "Regional 220 Intertie Channel" with recommendations from both groups that it be adopted nationally and be included in the overall national 2-meter bandplan. The concept here is to keep the people of 220 MHz in contact with one another without the need of synthesized radios or special equipment. Rather, each system provides a downlink to the common meeting ground of 145.56 MHz and conversation is automatic. In the few short weeks since the channel was announced, a goodly number of systems have initiated such operation and each week finds new ones. Ray has reported that Arizona may soon initiate a similar operation on 145.56 and hopes that it will eventually become a national 220-MHz intertie whereby information can be sent all over the place by relay from district to district. The ability to continually communicate is very important, more so now than ever before. VHF propagation tends to limit our communication ability. The 220 downlink concept is a step toward remedying this.

"AND THEN THERE IS 14.285 MHZ" DEPARTMENT

Another frequency to keep your ears on is 14.285 MHz on 20 meters. It seems to have become a very popular lowband intertie channel for VHF and UHF remote downlink HF operation and LW is getting quite a few reports of such operations. Actually there is no particular reason that 14.285 was chosen by the remote people. The story is simply that the first remote to install a 20-meter downlink radio just set it there and everyone else seems to have taken the same route. There is no way to know how many remotes downlink to 14.285; however, the number is growing rapidly. While it's doubtful that many systems will go to the trouble of installing a 20-meter SSB radio and antenna at their site, the fact is that a number have and users report it to be one heck of a way to operate HF while eating dinner at the local diner or driving home on a crowded freeway. A number of remotes are reported to have all-band/all-mode HF capability which includes remotely tunable receivers and remotely rotatable beam antennas. Squelch tales and "PL" on 20 meters? What next!?

Awards

from page 28

band, mode, or time restrictions. General certification rules apply.

ZONE 3 AWARD

This award is offered in four (4) levels of operating achievement:

1. Basic Zone 3 Award. This award is issued to those stations submitting written evidence of having worked an amateur in each state and Canadian province in Zone 3. These geographical limits would include Arizona, Oregon, California, Nevada, Utah, Washington, and the province of British Columbia. Contacts may be made in any amateur band and mode and must have been made on or after January 1, 1946.

2. Master Zone 3 Award. Applicant must follow the same rules as stated for the Basic Award with the exception that all contacts must be made with a station located in the capital city of each state and province in Zone 3.

3. Special Zone 3 Award. This special award recognition requires the applicant to work five (5) Zone 3 stations whose last call letters spell the word BEARS. All other rules for the Basic Zone 3 Award apply.

4. Extra Zone 3 Award. This award combines the difficulty of both the Master and Special Award and undoubtedly becomes the most sought-after in the Zone 3 program. To qualify, contacts must be made with stations located in capital cities of Zone 3 states and provinces. In addition, the last letters of their calls must spell the word BEARS.

All awards offered by the BEARS are available free of charge. Applicants must make a self-prepared list of required contacts, including the city and state of each amateur contact claimed, the date of each QSO, the band, and the mode. This list must be verified by at least two (2) amateurs, Technicians or above, an officer of an active radio club, or a notary public. In each case, the applicant must have written confirmations on hand for each contact claimed. Submit your award application to: The Boeing Employees' Amateur Radio Society, Willis Propst K7RS, 18415 38th Avenue, South Seattle WA 98188.

Representing the Finnish Amateur Radio League, Inc., our good friend Mervi Huotari, award manager for SRAL, writes to inform us about the beautiful OH series of awards being offered by this dedicated organization in northern Europe.

Mervi indicates that all applications must be forwarded to the attention of the SRAL Award Manager, PO Box 306, Helsinki 10, Finland, and suggests that QSL cards not be sent. Instead, Mervi states that all claimed contacts should be verified locally by two licensed amateurs, a club official, or a notary public.

To be valid, all contacts qualifying for the OH-series awards must have been made since June 10, 1947. The OH awards consist of the following:

OHA

1. Applicants in Denmark, Norway, and Sweden need contact with at least 50 different OH stations, including 8 OH call areas on one band, plus 8 different OH call areas together on other band(s).

2. Other European applicants need contact with at least 20 different OH stations, including at least 7 OH call areas. The maximum number of contacts per band is 15, so at least two different bands must be used.

3. Non-European applicants need contact with 15 different OH stations, including at least 5 OH call areas on any band or combination of bands. Contacts made on 3.5 MHz will count for two contact points each.

4. CW, phone, or mixed mode contacts count. The minimum acceptable reports are 338 RS(T). Contacts with Finnish maritime mobile stations do not count.

5. The award fee is 5 IRCs, to be sent with each application.

6. The OH8 stations with suffixes ND, NJ, NS, NV, NX, OA, OB, OC, OG, OI, ON, OP, OQ, OR, OU, OX, OZ, PA, PB, PD, PF, PL, PM, and PQ are counted as OH9 stations if contacted before June 1, 1954.

OHA-100

The applicant must have worked at least 100 different OH stations, including all 10 call areas on one band plus (again) all 10 OH call areas on another (one) band. The 100 stations must all be different, but in order to meet the call area requirement, the same station may be worked on different bands; in this case, the total number of contacts will be over 100. All authorized bands may be used, as well as CW, phone, or both.

The application list must be in district and alphabetical order (only callsigns and dates), giving separate declaration of the required 2 x 10 call areas/bands.

See also paragraphs 4, 5, and 6 of OHA rules above.

OHA-300

The applicant must have worked and confirmed at least 300 different OH stations, including all 10 OH call areas separately on each of three bands, i.e., 3 x 10 OH districts. The 300 OH stations must be all different, but in order to meet the call-area/band requirement, the same OH station may be worked on different bands. In this case, the number of QSOs will exceed 300. All bands, CW, and/or phone may be used.

The application list must be in district and alphabetical order (only callsigns and dates), giving separate declaration of the required 3 x 10 districts/bands.

See also paragraphs 4, 5, and 6 of the OHA rules.

OHA-500

This award will be available to any foreign applicant for confirmed contact with 500 different OH stations, regardless of time, mode, or band used. For OH applicants, only contacts made since February 1, 1967, will count.

A list of the 500 OH QSL cards on hand must be submitted to the awards manager. As with all OH-series awards,

this list must be verified by at least two amateurs, a club official, or a notary public. The award manager reserves the right to call for any QSL to be submitted in support of any claim. This list must be written in alphabetical order by callsign, and no other details are necessary.

The OHA-500 is given to qualified applicants free of charge, compliments of SRAL.

From down under, the boys at the Wireless Institute of Australia were kind enough to forward the March, 1979, issue of their publication, *Amateur Radio Journal*. In that edition, WIA columnists presented the entire portfolio of WIA-sponsored achievement awards. We will review the well-known Worked All VK Call Areas Award (WAVKCA):

WAVKCA

Objects:

1. This award is offered by the WIA as tangible evidence of the proficiency of overseas amateurs in making contacts with the various call areas of the Commonwealth of Australia.

2. The award may be claimed by any amateur in the world who is a member of an affiliated society of the IARU, but no Australian amateur will be eligible.

Requirements:

1. A handsome certificate will be awarded to any applicant who makes contacts with Australian amateur stations in the areas shown in Table 1. A total of 22 contacts must be made.

Operation:

1. Contacts between overseas stations and Australian stations must have been made on or after January 1, 1946.

2. Contacts may be made using any authorized frequency band or type of emission permitted to Australian amateurs, but crossband contacts will not be allowed.

3. No contacts made with ship or aircraft stations in Australian territories will be eligible, but land-mobile or portable stations may be contacted provided the location at the time of contact is shown on the confirmation.

Verifications:

1. The applicant must submit proof in the form of QSL cards or another form of written evidence confirming two-way contacts have been made. Such verification must show the date and time of contact, call of the station worked, type of emission and frequency used, signal reports, and location (portable or land-mobile stations only) of the stations contacted.

2. If the applicant is a member of a society which has a reciprocal agreement with WIA to verify claimed contacts for its members, submit your QSLs to that society, being sure to enclose sufficient postage fees for their safe return.

Application:

1. Applicants should submit their certified list of contacts and/or list of contacts with QSL cards to the Federal Awards Manager, WIA, Postbox 150, Toorak, Victoria 3142, Australia. There is no fee for the award—it's compliments of WIA!

Join me next month as we span the globe in search of operating incentives such as those which appeared this issue. Should you learn of any operating awards in the meantime, why not share them with our many readers throughout the world? I'd be pleased to hear from those who read this column and would appreciate your comments both pro and con, any suggestions you might have, and most certainly any award input you might care to submit.

Territory	Call Area	QSLs required
Australian Antarctica Heard Island Macquarie Island	VKØ	1
Australian Capital Territory	VK1	1
Lord Howe Island State of New South Wales	VK2	3
State of Victoria	VK3	3
State of Queensland Thursday Island Willis Island	VK4	3
State of South Australia	VK5	3
State of Western Australia	VK6	3
Flinders Island King Island State of Tasmania	VK7	3
Northern Territory	VK8	1
Admiralty Islands Bougainville Island Christmas Island Cocos Islands Nauru New Guinea New Ireland Norfolk Island Papua Territory	VK9	1

Table 1. In areas above where more than one confirmation is required, contacts may be made with any or all of the territories grouped together. VK9: Where a territory is no longer under Australian jurisdiction, contacts up to the date of independence will be accepted.

Review

AMATEUR TELEVISION IN A NUTSHELL

Sooner or later every ham gets the urge to try something new and different. For some this means a better rig. The more adventuresome types may want to try a new mode. Fastscan television is one such opportunity. Activity starts at 432 MHz and is even found in the microwave bands. Until recently, there has been no universally good source of information for the beginner. This void is partially filled by the book, *Amateur Television in a Nutshell: Everything you need to know to build or operate your own ham TV station.*

The book was first published in early 1978 by Henry Ruh WB9WWM, the publisher of *A-5 Magazine*. Despite its 8½" x 11" cover size, there are only 60 pages of text, making it truly a "nutshell" of information; price is $5.00. The contents include a short theory section followed by chapters on receiver, transmitter, and antenna construction projects. A listing of ATV operators, several charts, and a few pages of advertisements comprise the rest of the book.

Since the world of video is new to most prospective ATVers, the author gives a rather detailed explanation of the TV signal and describes how a camera works. Once the basics are mastered, it is time to think about gear. Ruh lists specific recommendations about the individual units an ATV station will need. The prices are sure to have changed, but the model and manufacturer information is likely to be useful for a few more years.

Although the easiest way to get involved in ATV is by purchasing ready-made equipment, many hams find that the long-term attraction of fastscan operation is home-brewing. The projects discussed in the book are lifted from the pages of *A-5 Magazine*. They are written in a cookbook fashion with little attention given to the mysteries of UHF construction. Despite the frequent occurrence of pictorial aids, a number of the photographs and diagrams are of questionable value because of blurry or crude reproduction.

Prospective ATVers are likely to ask, "What can I do with my station once it is built?" *Amateur Television in a Nutshell* lacks any good answer. For amateurs new to UHF and video, the best source of information and help is probably an experienced ham, preferably living nearby. *Amateur Television in a Nutshell* is not a replacement for practical knowledge, nor is it likely to be a timeless reference of the subject. If you have a genuine interest in the subject but don't know how to get started, do yourself a favor and buy a copy of *Amateur Television in a Nutshell.*

Ham Help

I have a Hallicrafters receiver, model S-40A, and I need alignment instructions and identification of the trimmer capacitors. I also have an Elmac Model A54H portable transmitter for which I need instructions for aligning the vfo and identification of the trimmer capacitors. I will be glad to pay a reasonable charge for copies and postage.

Benford Rhodes W4RKW
126 Elizabeth St.
Jacksonville NC 28540

I am doing experimental work in radio spectrum efficiency. I am in urgent need of a spectrum analyzer, which I cannot afford. I need an inexpensive method to adapt a B&K 10-MHz, dual-beam, triggered-sweep oscilloscope for my needs. I am especially interested in the region of 100 kHz ± 5 kHz.

Roy Hickman, Sr.
PO Box 572
Wauchula FL 33873

I need a schematic and/or manual for a Viking 122 vfo. I will pay for photocopying and shipping.

Contests

from page 18

formation plus 2 IRCs or one dollar. DX stations will qualify by working XJ3TBC on 2 different bands. Each day an appropriate prize will be given to the lucky Canadian or US amateur working XJ3TBC closest to a preselected time. Amateurs visiting the station are invited to and will receive a commemorative memento of their participation.

SARTG WORLDWIDE RTTY CONTEST
Contest Periods:
0000 to 0800 GMT
Saturday, August 18
1600 to 2400 GMT
Saturday, August 18
0800 to 1600 GMT
Sunday, August 19

The contest is sponsored by the Scandinavian Amateur Radio Teletype Group. Use all bands 80 through 10 meters on RTTY only. Operating classes include single-op, multi-operator/single-transmitter, and SWLs. The same station may be worked once on each band for QSO and multiplier credits. Only two-way RTTY QSOs will count.

EXCHANGE:

RST and QSO number.

POINTS:

QSO with your own country is 5 points, with other country in the same continent is 10 points, with other continent is 15 points. In USA, Canada, and Australia, each call area will be considered as a separate country. Use the DXCC list and each district in the three countries listed above for multipliers. Note: A contact with a station which would count as a multiplier must be found in at least 5 logs, or contest logs from the multiplier station must be received in order to be valid. Final score is the sum of QSO points times the sum of multipliers. SWLs use the same rules for

Results

1979 US SSTV CONTEST RESULTS

Once again, the annual SSTV Contest was a joyous success and all contestants reported having the times of their lives during this informal event. As you will recall, this US-sponsored SSTV contest is held during the second full weekend of each March.

The overall 1979 SSTV Contest winner was Roland Soucie N6WQ of Costa Mesa, California. As you can see in the contest tally, Roland's victory was practically a landslide—and he followed the correct (shorter contest times) rules which were published in 73 *Magazine*. Roland also took the awards for most countries worked and the most continents worked. Since John WB9OGS and Roland N6WQ tied for most states/provinces, both SSTVers will receive awards for their accomplishments.

Brooks W1JKF and Dave K4TWJ wish to thank everyone who participated in the SSTV Contest for making this event a tremendous success. We tried to expand this year's contest into a jointly-sponsored event which was announced in all the amateur magazines. Unfortunately, CQ published incorrect contest times while QST mentioned the contest somewhere in the back of an issue, under QCWA happenings or the like. I never found that announcement!

On-the-air contest monitoring which Brooks and I did indicated an extremely congenial spirit of competition and courtesy among all SSTVers. Many operators would actually wait in turn for QSOs to avoid possibly QRMing others.

Several SSTVers have recommended changes for next year's contest. These recommendations were acquired during the contest, via the Saturday SSTV Net, and via mail. The prime consideration involved making this contest an international affair. Before this plan can be adopted as a unanimous effort, we need opinions (and assistance!) from all SSTVers. If the contest is to be truly international, then prime time should also be available to our friends around the world. What operating schedules would you deem necessary? How should an awards and publicity program be implemented? Please contact W1JKF and K4TWJ with your opinion . . . soon! The Saturday SSTV Net is usually this activity's planning table. See you then?

1979 SSTV CONTEST COMMENTS

"The SSTVers are a great bunch of hams who should be commended for their sportsmanship and courtesy during the contest."—K4FJK.

"Rig acted up once, but I gave it the old gravity test from 3 inches off the table and it straightened right up."—WA9LLQ.

"Great contest, but it needs a magazine sponsor."—W2GND.

"And one that can get information right and illustrate an interest in SSTV, like *73* continuously does. Right, Wayne?"—K4TWJ.

"Although I couldn't stay in the whole time, it was loads of fun."—K8EMI.

"Great—can't wait until next time."—WB9RYP.

"In our Dutch magazine, *Electron*, contest rules were not clear."—PAØDXY.

"Disappointing was working 2 DX stations in the same country."

"Mixed emotions was working 2 mobile SSB contacts and sending them video before finding out they did not operate SSTV. My average was five contacts an hour."—AFØK.

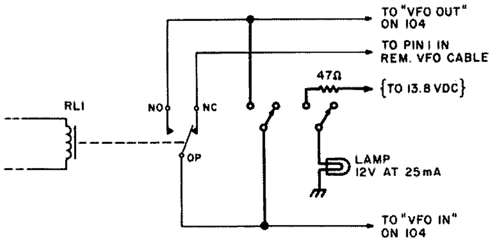
Corrections

After my article appeared in the April, 1979, issue of *73* ("The Heath/Kenwood Connection"), I found a small refinement which could be added to the project. Its total cost is small and it should take only a few minutes to install.

I realized that one could use some method of instantly bypassing the remote vfo aside from using the function switch on the remote vfo. For example, in case of some unexpected failure in which the remote vfo and its function switch are inoperative, it would be nice to immediately go to the rig's vfo. I have not had any such failure as yet, but anything can happen in electronics.

A side benefit was found when it was discovered that *both* vfos (internal and remote) could be used at the same time. This is very nice when one wants to find a clear spot to move to while still in contact. Also, one could monitor a sked or calling frequency while tuning around.

The only parts needed are a lamp, a resistor, and a switch. The lamp I used is a Radio Shack 12-volt/25-mA lamp with red lens and mounting clip. Since I felt it was a little too bright, I put a 47-Ohm, ¼-Watt resistor in series to prolong the bulb's life. (See Fig. 6.)



Revised Fig. 6, "The Heath/Kenwood Connection."

Why install a red lamp? It's okay to *listen* on two frequencies at the same time but not to *transmit* on two frequencies at the same time. In fact, I considered using a push-button switch which would then allow multi-frequency operation *only* whenever one makes the conscious effort of pressing the switch. I recommend giving serious thought to this alternative. If a toggle switch is installed, the bright red lamp may prevent giving an SSB CQ with the other vfo on the CW segment of the band!

The addition meant placing the interface box up front where it's more accessible and visible but I feel it's worth it.

Reinbeck, Hudson IA 50643.

Ham Help

I am blind and have been bedridden with spinal arthritis for nine years. All this time I have spent living in hospitals, from which I am writing to you now. I hope your readers can help me.

I would like some friends out there beyond my four walls to help me get a two-meter set, a handie-talkie, or perhaps a mobile, though I don't drive a car. I need some Morse code tapes, although I do know some characters already. I need to learn the radio theory on tape cassettes, also.

I became more interested in ham radio when I found myself in a county hospital and confined to bed without a phone in my room. On my Sony radio receiver, on 147 MHz, I accidentally picked up some hams, and I discovered that they were on repeaters and I could pick them up from fifty miles away in the San Fernando Valley. I heard other blind ham operators on the repeaters, also. And I wish I could talk to some of them. Some are very humorous and intelligent; others argue, but it's all interesting. I heard one or two young ladies, also. I know Phil, Scott "KMO," and Bob "HMC," but I can't talk to them. Darn it!

What is this synthesizer and simplex they talk about? I think it's pretty good for my indoor Sony radio to pick them up in this concrete and steel building, though I am six stories up in Torrance.

I need live visitors and those who will read for me since I am blind. My hospital desk phone is (213)-533-2783 (though I unhappily will go back to a nursing home). Please call and write me, hams, readers, and pen pals.

First of all, I'd like to thank everyone who helped me out with information on the Knightkit R-100A receiver. I really appreciated it.

Next, I wonder if anyone could furnish me with a schematic for a Hallicrafters model CRX-102 VHF receiver. It's a transistorized receiver that covers 144 to 174 MHz. The chassis number is SN 1312449. Also, can anyone get me a schematic for an EICO 720 CW transmitter? Thanks.

John Vercellino WB9OVV

Downers Grove IL 60515

I would like to get in contact with a ham in the Santa Fe NM area, who could help me obtain my General ticket. I also am in desperate need of a manual, schematic, and alignment info for the following equipment: Hammarlund HQ-110 receiver, Motorola HT-220 hand-held transceiver, and a General Electric Royal Executive FM transceiver. Any help will be greatly appreciated. I will be more than happy to pay for copying costs and postage.

Mark A. Arnold

Santa Fe NM 87501

DX

from page 10

Watch 7007 and 21035 kHz from 2330Z.

6O1FG returned to Italy from Somalia on April 2 with far fewer contacts than were hoped for. The political situation is still not settled enough for good DXing. He would have liked to have spent more time operating, but conditions just were not favorable.

W2TDQ runs a twice weekly sked with SV9JI on Crete. Watch 14288 kHz on Tuesdays and Fridays from 2100Z.

JA7JT/JD1 left Ogasawara and set up shop on Marcus Island. He plans to stay through August when he will return to Ogasawara. QSL to JH7BRG.

N4WX kept the faith and finally came up with a ZD9BM QSL for a 1970 contact.

Jacky F6BBJ advises that he still has logs for his previous activity from St. Brandon VQ8CFB, Chagos VQ9SM, and Agalega 3B6CF, and can supply QSLs on request.

Before his untimely death last year, ZE7JX provided many stations with a new one on 160 meters. Steve Reichlyn AA4V has obtained those logs and QSL requests should be directed to Steve at Box 9096, Columbia SC 29290.

OZ8AE was active from Macquarie Island signing VK0JC just at the end of 1978. QSLs can be directed to OZ6MI but don't expect any return until OZ8AE makes it back to Denmark later this year.

In lieu of other routes, T2 stations can generally be QSLed via Weather Station, Funafuti, Tuvalu, Central Pacific.

For any of you adventuresome types looking around for somewhere new to vacation, W9KNI reports the following areas have been silent since at least January 1, 1975: BY, CE0X, VK0H, VU2L, XZ, YA, ZA, 3C0, 3X, and 7O. There have been rumors of 3X, YA, and 7O, but these have not been authenticated. Take your pick. Any one is guaranteed to draw a crowd.

P29JS checked into the possibility of obtaining Andaman operating permission while on a short trip to India. It seems licensing requirements have been relaxed somewhat, but he is still waiting for official word.

Ex-EP2VH, Vern Hardy, is back in Florida, but his logs covering two and a half years of activity in Iran, were confiscated. Vern is not sure if he will ever get them back.

The DXCC workload at the ARRL has increased tremendously with the large jump in the number of licensed amateurs in the last couple of years. The result will probably be, among other things, limiting submissions of new countries to only twice a year.

HC5EE passes along word that HC5RG was killed in a plane crash April 30th while searching for another downed aircraft.

CR9AJ is returning to Portugal where he will be signing CT1ADP. Torres has provided most of the CR9 activity the past couple of years and will be missed. His new address is PO Box 2676, Lisbon, 1100, Portugal.

S2BTF still shows regularly on the weekends on 14225 kHz after 1200Z.

Although the original intent was for DL8DC to handle the QSL chores for TY9ER, plans were changed and cards should be routed through W2TK. This decision was made so that some of the more obnoxious entries could be edited from the log. If your card came back marked "not in log," maybe a little self-examination of your DX operating habits is in order.

A51PN has been showing most Tuesday/Wednesday/Friday mornings after 1145Z on a 14265/14195 kHz split frequency operation. Listen on the long path and QSL direct.

KX6PP has been showing around 0830Z on 14252 kHz. QSL to 1406 34th Street West, Birmingham AL 35218, with the usual SASE.

ZD7HH needs Maine, Vermont, and Wyoming to complete his WAS. Look for him on 21291 kHz from 2100Z. QSL to W4FRU.

ZS2MI has been showing around 14240 most weekdays at 0630Z in a list-type operation. Look for WA2JUQ making the list. QSL to WA2IZN, 225 Route 17, Upper Saddle Brook NJ 07458.

Ex-EP2IA has returned to England where he now signs G3SXW. Roger has shipped his EP logs and a stack of blank cards to W4YE for processing. Any QSL requests should be directed there.

Someone at the FCC monitoring station in Anchorage apparently got hold of an outdated list of banned countries and issued pink slips to several rather startled DXers for contacts with HS stations in Thailand. The notices stated that contact with amateur stations in Thailand was forbidden and gave the offenders ten days to reply. A quick check with local FCC offices and the ARRL showed no change in HS status, much to the relief of the "guilty" parties. We wonder if the DXCC Desk would accept those pink slips in lieu of a QSL for HS credit.

Although the recent YV0AA activity should have slowed the Aves Island demand for awhile, it appears that there is a permanent population of scientific types on Aves and not one, but two, permanent amateur stations. It seems that YV5HAM and YV5HQE are both located on Aves Island and are used for handling traffic back to Venezuela. They do not sign with the standard YV0 prefix because they do not want to attract the unwanted attention of the DX types. If you habla espanol, you might listen for them daily below 14200 kHz.

With rumors abounding that a Swedish group had permission to operate in Albania, the sudden appearance of a station signing ZA5T and giving SM2DMU as his QSL manager, gave many the hope that finally here was a true-blue Tiranian. Unfortunately, it turned out to be Tirana Slim. Someday...

UK1PAA has been showing from Franz Joseph Land on a very limited operating schedule. The station is crystal-controlled on 14030 kHz and the time to listen is around 1400Z. Some reports also have him on fifteen meters around the same time on 21015. He seldom stays around for long, but he will apparently be there for some time.

Jacky F6BBJ, one of the operators on the Clipperton Island effort as well as several other expeditions, is planning a 3B6 St. Brandon operation in September. Jacky is a top operator and always manages to run up a large QSO total wherever he goes.

The KP4AM/D logs for the Desecheo operation arrived at the Northern California DX Foundation for QSL processing in late May. Although there were some 20,000 entries in the logs, all cards were in the mails before the end of June. If you haven't received yours as yet, it might be time to try again. The ARRL DXCC Desk announced they would begin accepting Desecheo QSLs September 1st... only for contacts made March 1, 1979, or later. That should clear up any questions concerning the earlier W0DX/D operation.

That TH8JM operation from the Central African Empire in May was apparently sans official permission, so there is some question concerning ARRL acceptance.

In response to our DX riddle in which three DXCC countries share the same prefix but are located within different continental boundaries, Charles Martin AB4I and John Reasoner WA4QMQ came up with VK0—Heard, VK0—Macquarie, and VK0—Australian Antarctic. Nice going, guys, but these are not the ones I had in mind. See what else you can come up with.

To improve our coverage of specific areas of DX interest, we are looking for a few reporters who would have time to send in a page or two each month covering happenings on their favorite band/mode of DXing. We need more information on OSCAR, SSTV, CW, Novice bands, 160 meters, VHF/UHF, channelized 10-meter AM, etc.

If you specialize in any of these areas and would like to have a monthly byline here in this column, write and let me know what your specialty is and we will try to assemble a top staff of super reporters.

That's all this month. Work a new one.

Thanks as always to the *West Coast DX Bulletin*, LIDXA *Bulletin*, and *Worldradio News*.

Contests

from page 141

scoring, but based on stations and messages copied.

ENTRIES:

Logs must be received by October 10 and must contain: band, date, time in GMT, callsign, exchanges, points, and multipliers. Use a separate sheet for each band and enclose a summary sheet showing the scoring, classification, callsign, name, and address, and in the case of multi-operator stations, the names and callsigns of all operators involved. Send logs to: SARTG, Contest & Award Manager, C. J. Jensen OZ2CJ, Meisnersgade 5, 8900 Randers, Denmark.

HELL DXPEDITION

W8TQE, the Adrian Amateur Radio Club, will give you a chance to work Hell, Michigan, between 1600 GMT August 25 and 1600 GMT August 26. The operating frequencies will be: CW—3710, 3565, 7110, 14065, 21110, 21065; SSB—3900, 7235, 14285, 21360, 28625. A colorful QSL certificate can be obtained by accompanying your QSL with a legal-size SASE and mailing it to: W8TQE, PO Box 111, Adrian MI 49221.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

10-GHZ RECORD EXTENDED

Not satisfied with holding the world's record for states worked on the amateur 10-GHz band (five), the record holders have been working to extend it to six ... perhaps seven. The sixth was worked, I'm glad to report.

It all started out last fall when Chuck Martin WA1KPS got interested in the Microwave Engineering Gunnplexers and got a pair of them perking. The first contact from New Hampshire to eastern Massachusetts was relatively easy. Oh, it took us about fifteen minutes to find each other while tuning one unit and sweeping the general direction of the hill a bit over 50 miles away. Eventually, we lucked onto both the right frequency and bearing and the contact was solid.

Later, Chuck made an expedition to a mountain in southern Maine, also well over 50 miles away. Again it took a lot of tuning and turning of the two transceivers before the contact was made. Both have to be on the right channel and pointed very close to the right direction. No dishes were involved at this time—just the Gunnplexers, with their little waveguide antennas.

Chuck then drove to Mt. Ascutney in Vermont, again over 50 miles from my mountain in southern New Hampshire, Pack Monadnock. It is no accident that I have a drive-up mountain within four miles of the *73* offices ... that's what attracted me to this area when I moved here, 17 years ago. I've been a VHF and UHF nut right from the earliest days of my hamming, starting out on 2½ meters, for those of you who remember that band. I ran a pair of 76s with their bases slotted for "efficiency" and was the terror of Troy (NY). That was before WWII ... forty years ago!

Next we needed to work New Hampshire, so Chuck drove to the top of Mt. Washington and we made it ... but that one was tough. We were both freezing in the cold winds, clouds were swirling around Washington, and the transceivers were not working well at all. In the light of later improvements, they had never been working more than marginally! But we did make it for an exchange of callsigns and signal reports ... whew! That was 106 miles, with faulty transceivers and no antennas to boost the signal.

It took two tries to get Rhode Island, and we had several frustrating failures with Connecticut. Just as Chuck had the transceivers working better and a two-foot dish ready to use, snow finally blanketed my mountain and that was that for the winter. When spring finally arrived, we tried to make it to Connecticut again, with Chuck even climbing trees to try and get the few extra feet of height needed. No go. Then we tried to make it through from the New York border ... again a failure. There was no strain when we tested the system out between the Pack and Mt. Greylock in western Massachusetts, but the path to New York was just not there.

Bigger problems call for sterner measures. The Pack is about 2,500 feet high and is usually excellent for VHF contests. It has the benefit of a toll road to the top ... the very top ... plus a fire lookout tower for a few added feet. About 12 miles away is Mt. Monadnock, a 3,500-foot lump whose top half is all rock. This mountain has a slight problem in that it is a 2½-mile hike to the top and the going is not easy. I'm almost 60 years old, my primary exercise is sitting at a typewriter all day, and I have no business climbing a 3,500-foot rock mountain. A few days of skiing during the winter helps a bit, but does in no way prepare one for hard mountain climbing.

Put into perspective, world records call for that extra effort, so I agreed to make the climb. That was not one of my better decisions. Chuck rounded up his team of Steve K1KEC and Eric WA1HON and headed for the best possible location in Connecticut ... near Somers. I rounded up our summer tech, Tim Daniel N8RK, and Sherry and we headed for Mt. Monadnock.

The first half was easy ... a dirt road. The second half was a pain. There was no scaling of rock faces—it was just a grueling climb up rocks for over a mile. It seemed to go on forever. We'd see what looked like the top just above us maybe 500 feet, but when we got there we would see another peak beyond that. Sherry, who is used to mountain climbing being like walking up Stone Mountain in Atlanta, said that this was between ten and a hundred times as difficult. Tim? At 17 years old, he went up like a mountain goat.

When I finally arrived, panting and a bit worse for wear at the top, I was greeted by a couple hams and a three-element six-meter beam! They'd packed 40 pounds apiece up there for some DXing on six meters, only to find a maximum of six contacts to be made. It was Sunday afternoon, with very little activity on six meters. There were a couple dozen hikers, all looking disgustingly fresh and rested.

Tim and I set up the 10-GHz rig and aimed it in the direction of Connecticut, coordinating the effort on 220-MHz simplex and, on occasion, on two-meter simplex. This was the easiest of them all ... contact was made almost immediately. Chuck's group was using a two-foot dish on top of a fire tower and we had the plain Gunnplexer, but mounted on a tripod this time for stability. The signal strength pin went right over full scale and then off scale! The voice was just like the other team was right with us. We did get some interference from the six-meter team breaking through on our

link. RFI, even on top of Monadnock!

The climb down was not much easier than going up. It didn't take as much grunting and straining up through the rough places, but it took a lot of care and knee-shaking jumps to rocks. I was lame for several days afterward with knee-cap shock. The thought that Chuck and his group might want to do this all over again for another try for the New York-New Hampshire path went through my mind with each and every rock that I climbed down . . . all one damned mile and a quarter of them.

Fortunately, the day was reasonably cool . . . perhaps around 80° . . . and beautifully sunny. Visibility was only about 30 miles in the haze, but then it was a natural haze caused by the trees and not smog. There is never anything but clean air in New Hampshire.

The team down in Connecticut didn't have to cope with climbing a rock mountain, but they did have their problems. Being considerably south of us, they had much hotter weather and suffered greatly from sunstroke and heat prostration. Steve became completely prostrated in the back of their van when the time came to disassemble their setup and carry it down the tower. Oh, the agonies we have to go through to become world champeens.

BITING THE LIFERS

A recent letter from Chapman (ex-New England director) to ARRL life members on ARRL Foundation letterhead asked for donations to set up a $100,000 slush fund for HQ to spend at Geneva this year.

For some reason, nothing was mentioned of the $100,000 fund which has already been set up for just this type of use. I'm reminded of the League saving money for years to buy a new headquarters building . . . money taken from the members as dues . . . and then, when they finally had enough money, running a building fund and collecting the same money a second time. And to cap that, they sold their old building for almost the cost of the new building. That's mainly how they built up that $2 million-plus they have in securities and banks.

It seems to me that this begging for more money calls for some whistle-blowing. They seem to be trying to make up for the recent bad management of the League by asking for donations in the name of WARC.

The $100,000 is still carried on the balance sheet of the League in their latest annual report . . . it is for "the defense of amateur frequencies." That would seem to cover WARC like a glove. The fund was set up years ago and has been used for undisclosed purposes and then refunded by the League at the end of each year. It would seem that members of the League are entitled to a detailed accounting of the money spent from this fund down through the years. Any publicly held corporation would have to account to the shareholders for such a mysterious fund . . . particularly when there is a serious question about it being used for the personal benefit of League officials. IRS, please note.

I think I join many members in hoping that the League will be more prudent at Geneva this year. At the last WARC, they had a huge suite in one of the most expensive hotels in town and entertained lavishly. Throwing money around like that is the Ugly American way and we need friends, not resentful enemies.

To sum it up . . . the ARRL Foundation is in disgrace over the resignation of most of its directors . . . a fact which HQ has refused to discuss or even let members know about. They already have $100,000 in cash set aside for just such an event as WARC, so the begging for $100,000 more stinks. If you have money to pour down rat holes, I'm sure you can find better charities than this one.

ARRL PROBLEMS

I see that the ARRL's Central Division convention was a monumental flop . . . eight exhibitors and about 400 in attendance. The magic seems to have gone out of ARRL conventions, and the active hams are staying away in record numbers. Compare this to the Atlanta Hamfestival, where, in spite of the severe gasoline shortages, the attendance was only down a bit from last year and the exhibit hall was packed solid with exhibits and people. Compare it with the St. Louis hamfest, where a first-time show filled the exhibit hall and packed the hall with attendees.

What were the differences? One was a matter of promotion, where Atlanta and St. Louis got extensive promotion in both *73* and *MICROCOMPUTING* magazines . . . ads and editorial. Another difference was the speaker program, where one had no one of a controversial nature . . . not even of any significance . . . and the others had speakers who packed 'em in. I suspect that the day is past when you can pull in a good crowd at a hamfest just by listing it in *QST*.

OUTLAW RADIOS

A recent attempt to amend a New Jersey law which prohibits the use of radios in cars capable of receiving police channels so that it would exempt amateurs was vetoed by Governor Byrne. Someone should make it a point to acquaint the governor with the facts of radio life and the ridiculousness of the whole charade.

Maybe a few years ago something like this could be legislated, but with the modern scanners there is no way to keep anyone who wants to from receiving police channels. Like guns, the laws only have an effect on the honest person. Criminals carry guns and are quite capable of buying and using radios which will receive police channels . . . and how can a policeman know? With just about every other car sporting some sort of special antenna, a car can be set up for CB, for hamming, for any of a hundred special services . . . or to illegally receive police channels.

If the police are looking for just one more rap to lay on a criminal once he has been caught, the ramifications for hams and other honest users of radios are much too great a penalty to pay. Virtually every mobile ham rig for VHF is quite capable of being tuned to a police channel. The scanners, which are being sold by the tens of thousands, can get just about every police channel there is, high- or lowband . . . and they are 12-volt jobs, just fine for mobile use.

Will someone please bring Governor Byrne up out of the 1950s? And perhaps someone should alert the New Jersey legislature that making it illegal to have radios capable of receiving police channels in cars is not going to have any effect on criminals . . . it will only harass non-criminals.

SPREADING THE WORD

One of the jobs that I feel a national amateur radio organization should do is lobby for us on a national level. This means organizing campaigns which will get amateur radio favorably into the media . . . articles in national magazines . . . demonstrations which are covered by television . . . promotion of ham activities during emergencies, etc. In case there is any doubt, we are not getting such a service from *any* of our national amateur radio organizations.

Individual clubs, in a few instances, have been doing a fine job of getting publicity, but unless you are terribly isolated from the general public, you must be aware that most people have no idea of the difference between CB and ham radio. We do need PR and we need it badly

Looking West

Bill Pasternak WA6ITF
24854-C Newhall Ave.
Newhall CA 91321

The last time I went on a Field Day outing was in the early sixties. I was a member of an organization known as the Flatbush Radio Club of Brooklyn, New York, and we took to the hinterlands of New York City. The place was Prospect Park, which sits in the center of Brooklyn. OK... so it wasn't really the hinterlands. It was fun, but through the years the memories of that outing grew faint.

Since moving to California, the closest I have come to taking part in a Field Day outing was the time I went from club to club showing the PARC Field Day film, *Field Day 1972*. In the seven and one-half years I have been here, something has always come up to make me miss Field Day. One year I was out of town, another time I had to work... you know the story. Well, this year it all clicked. The San Fernando Valley Amateur Radio Club was holding its Field Day operation on a hill not twenty minutes from my house. I had film in my Polaroid in addition to 600 feet of Super 8 film. Most important, I had the time and the opportunity to attend. The lure was overwhelming...

If you have never experienced a real Field Day operation, you've missed something important. This is true gut-level amateur radio operation at its best. It's you the amateur versus the bands, the elements, and the odds. To me, the whole idea of Field Day is not whether I win or lose, but rather the camaraderie that is shown among amateurs during such an event. The San Fernando Valley Amateur Radio Club is an excellent example of such fellowship.

Let me tell you a bit about the SFVARC. It is a true amateur radio club with members whose interests go in many diverse directions. Unlike most clubs of this era, the SFVARC does not own or operate a repeater, nor does it ever plan to. In fact, a few years back I offered them such a device and it was rejected. It is not that SFVARC members don't like repeaters—far from it. Most of the members can be found operating the myriad of two-meter and 220-MHz systems that abound in this locality. However, to the SFVARC, a repeater is nothing but a way of extending the communications range; with over 300 operational 2-meter repeaters in southern California, there is no need for yet another. So, while most members do operate VHF or 2-meter FM, they do so using the existing relay facilities.

Rather than worry about running a repeater, the SFVARC looks in other directions. It does such things as provide communications for March of Dimes walk-a-thons and work with "Santa" at Christmas to help bring joy to children in hospitals. The best way to describe the SFVARC is to say that they epitomize the concept of an amateur radio club in the truest and broadest sense. Perhaps that is why Field Day with SFVARC was so much fun. There were about a dozen dedicated people from the club spending almost thirty-six hours on a remote California hilltop enjoying each other's company and their amateur radio hobby. They were fulfilling a dream that could only be fulfilled once a year. Being together enjoying the experience was the point of their hilltop excursion. I could only spend Sunday with them, but it was well worth it. My memories of the past were rekindled and somehow I felt more like a "real ham."

Ever wonder how a film is produced? Here's the secret... teamwork! (Photo by Bill Orenstein KH6IAF.)

A NEW MOVIE

Hollywood, which has brought you such epics as *The Poseidon Adventure, Two For the Seesaw, Charlie*, and other great moments in cinema, is now proud to announce another achievement. *The World of Amateur Radio* was produced by a man I consider to be a true cinema artist, Dave Bell W6AQ. I am writing this only an hour after leaving Dave's Hollywood studio. We just screened the first answer print of this new film and the consensus is that it is a superior work. With Dave Bell as the film's producer, the results were not surprising. In my opinion, he is a genius in his chosen profession. He knows his business, knows how to get a job done properly the first time out, and has the ability to lead others in the proper direction. Being able to work with someone like Dave has been a real honor and a truly rewarding experience.

The World of Amateur Radio is fast-paced, relevant, and covers most aspects of our amateur radio world. NBC-TV News correspondent Roy Neal K6DUE is the film's host and chief narrator. There are contributions from Senator Barry Goldwater K7UGA, Arthur Godfrey K4LIB, and Stu Gilliam WD6FBU, and special appearances by Dick Van Dyke and His Majesty King Hussein of Jordan JY1. The film was produced by Dave Bell Associates for the American Radio Relay League and it will soon be available from the ARRL. I am happy to say that this is one time when the League is truly serving the amateur community; it should be applauded for its fine work on our behalf. Through the cinematic expertise of Dave Bell, the ARRL is providing us with the type of visual vehicle we need in order to explain what amateur radio is all about. As this is written, the film print is en route to Geneva, Switzerland, to be presented to those who will be deciding our future—the delegates to the World Administrative Radio Conference.

The World of Amateur Radio is our world, and now, thanks to Dave Bell and the ARRL, we will be able to share it with virtually everyone. All who worked on the project sincerely hope that you will enjoy the film. I have one request: At present, only one print of the film exists, and that print is in Geneva. It will be a few weeks before distribution prints are available. Please do *not* contact Dave Bell Associates or the ARRL requesting the film. Instead, keep watching for ARRL official bulletins, *HR Report*, the Westlink Amateur Radio News, and this column. All these sources will let you know the moment the film is ready for release. While we wait, readers of this column may want to start recruiting non-amateur groups for introductory talks about amateur radio, using the film as the focal point of the meetings. While we amateurs will enjoy viewing it, it's far more important that the film be seen by the non-amateur general public. It is time for the rest of the world to discover us and our service capabilities. Therefore, it is extremely important that the film reach as wide an audience as possible. Public schools, public television, civic groups, and church groups can all be approached. This is where *you* come in. The film will do no good sitting on a shelf. To be effective, it must be seen. Any takers?

Continued on page 153

New OMNI/SERIES B Filters The Crowd

The new OMNI/SERIES B makes today's bands seem less crowded. By offering a new i-f selection that provides up to 16 poles of filtering for superior selectivity. And a new Notch Filter to remove QRM. No other amateur transceiver we know of out-performs it.

NEW I-F RESPONSE SELECTION. OMNI comes equipped with an excellent 8-pole 2.4 kHz crystal ladder i-f filter which is highly satisfactory in normal conditions. But when the going gets rough, the new OMNI/SERIES **B**, with optional filters installed, provides two additional special purpose i-f responses.

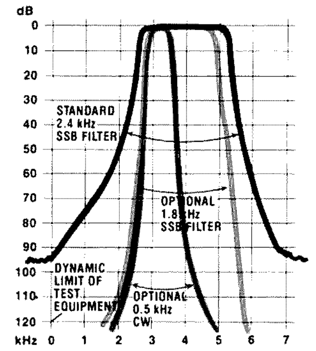
The 1.8 kHz crystal ladder filter transforms an unreadable SSB signal in heavy QRM into one that gets the message through. The 0.5 kHz 8-pole filter provides extremely steep and deep skirts to the CW passband window which effectively blocks out even the very strong adjacent signals.

Both of these filters can be front-panel switched in series with the standard filter to provide up to **16 poles** of filtering for near-ultimate selectivity. In addition, the standard CW active audio filters have three bandwidths (450, 300, and 150 Hz) to give even further attenuation to adjacent signals. In effect, OMNI/SERIES B has six selectivity curves—three for SSB and three for CW. That's true state-of-the-art selectivity.

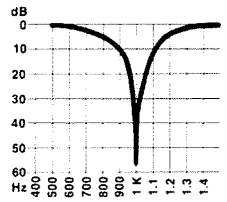
NEW NOTCH FILTER. A variable frequency notch filter in OMNI/SERIES B is placed inside the AGC loop to eliminate interfering carriers and CW signals without affecting received signals. Attenuation is more than 8 "S" units (over 50 db) for any frequency between 0.2 kHz and 3.5 kHz.

OMNI/SERIES B RETAINS ALL THE FEATURES THAT MADE IT FAMOUS.

All solid-state; 160-10 meters plus convertible 10 MHz and AUX band positions; **Broadband design** for band changing without tuneup, without danger;



OMNI/SERIES B I-F RESPONSES WITH STANDARD AND OPTIONAL FILTERS.



NOTCH FILTER PERFORMANCE ADJUSTED TO 1 kHz POINT.

TEN-TEC, INC.
SEVIERVILLE, TENNESSEE 37862
EXPORT: 5715 LINCOLN AVE., CHICAGO, ILL. 60646

Choice of readouts —OMNI-A for analog dial or OMNI-D for digital dial; **Built-in VOX and PTT** facilities; **Selectable Break-in,** instant or delayed receiver muting; **Dual-Range Receiver Offset Tuning,** ±5 kHz or ±0.5 kHz; **Wide Overload Capabilities,** dynamic range typically exceeds 90 dB and a PIN diode switched 18 dB attenuator is also included; **Phone Patch Interface Jacks; Adjustable ALC; Adjustable Sidetone; Exceptional Sensitivity; 200 Watts** input to final with full warranty on final transistors for first year, pro-rata for 5 years; **100% Duty Cycle** for RTTY, SSTV or sustained hard usage; **12 VDC Circuitry** for mobile use, external supplies for 117/220 VAC operation; **Front Panel Microphone and Key Jacks; Built-in 25 kHz Calibrator** in analog dial model; **Zero-Beat Switch; "S"/SWR Meter; Dual Speakers; Plug-In Circuit Boards; Functional Styling,** black textured vinyl over aluminum "clamshell" case, complementary nonreflective warm dark metal front panel; **Complete Shielding; Easier-to-use size:** 5¾"h x 14¼"w x 14"d; **Full Options:** Model 645 Keyer $85; Model 243 Remote VFO $139; Model 252MO matching **AC** power supply $139; Model 248 Noise Blanker $49; Model 217 500 Hz 8-pole Crystal Ladder **CW** Filter $55; Model 218 1.8 kHz 8-pole Crystal Ladder **SSB** Filter $55;

OMNI owners note: Your OMNI can be converted to a SERIES B model at the factory for just $50 (plus $5 for packing and shipping). The notch filter replaces your present squelch control and provision is made for the two additional optional filters; a partial panel with new nomenclature is provided. Contact us for details.

Model 545 Series B OMNI-A $949
Model 546 Series B OMNI-D $1119

Experience the uncrowded world of OMNI/SERIES B. See your TEN-TEC dealer or write for full details.

ARRL INTRUDER WATCH

Our recent comments concerning the "woodpecker" and other unauthorized encroachments into the amateur bands seem to have unintentionally opened a Pandora's Box of complaints directed at the ARRL-sponsored "Intruder Watch" program. Now, before you groan and say, "Won't those guys at *73 Magazine* ever get tired of blasting the ARRL?", let me assure you that Dallas is a long way from Peterborough and that the editor of this column has been a League member for over twenty years and has no axe to grind with the ARRL. The purpose is to simply find out what is going on in the Intruder Watch program and to determine if it is doing the job it was created to do.

If you have had any recent experience with the Intruder Watch program, either good or bad, let us know. Since negative opinions are most often voiced, we are especially interested in receiving reports of positive results as a direct result of this program. To keep everything aboveboard, letters postmarked Newington or Peterborough will not count.

If you're wondering what all this has to do with DX, try working some on 40 meter SSB.

NOVICE CORNER

Now that you have switched to UTC time for logging DX contacts and making out QSLs (you have switched, haven't you?), it is important to remember to always advance the date at 2400 UTC. QSL managers report that the most common mistake made in filling out QSL cards is neglecting to advance the date at the proper time.

That same error can easily cause you to miss a sked of a DX net. Suppose you read in this column that a station you need has a schedule with his QSL manager at 0000Z on Fridays, but when you show up Friday at the scheduled time, no one is there. The reason no one is there is probably because you're 24 hours late. 0000Z Friday is exactly the same time as 2400Z Thursday. In Texas, for instance, 0000Z on Friday is 7 pm Thursday CDST. It's easy if you just remember that 2400Z is midnight and the date always advances at midnight.

HEARD ON THE BAND

Dave Schoen N2KK and Scotty Meadows K5CO are planning an extensive series of operations later this year in the Indian Ocean and African areas. The plan is to operate independently from some areas and then join forces for the important ones. Dave will leave the States in mid-November in time to set up in J28 Djibouti for the CQ WW CW Contest. From Djibouti he will head over to FR7 Reunion Island to begin a long series of Indian Ocean efforts. Initial plans call for stops at 3B8, 3B7, and 3B9. He is also looking at possible FH8, D68, FR7/G, and FR7/J operations, as well as some of the more rare East African countries. Dave is a professional photographer and his assignment will be to photograph the area for tourism promotion. Scotty, who has operated from TT8, 5A, 7P8, and 9H1, will join up with Dave after their plans have firmed up. Early hopes are for better than 100,000 QSOs total for the operation. We should have more news on this one next month along with the suggested QSL routes.

Reports continue to surface on some really big gun efforts later this fall aimed at one or more of the following areas: 7O1 Yemen, VS9K Kamaran, 8Z4 Neutral Zone, or SY1 Mt. Athos. Mt. Athos and the Neutral Zone seem to be the betting favorites.

KH6LW showed as expected from Kure Island with a good signal to stateside. QSL to Richard Senones KH6JEB, 95-161 Kauopae Place, Mililani Town, Hawaii 96789.

According to the McNish-Lincoln and Sargen predictions, the sunspot maximum will occur in November of this year hitting a smoothed high of 156. After that, a gradual decline will begin, bringing the June, 1980, figure down to around 145. There will be good times for the deserving DXer for several months yet.

A new country emerged from the Pacific Ocean on July 12th. The name is Kiribati and it was formed from, among others, the Gilbert Islands, the Line Islands, and the Phoenix Islands. Christmas Island, covering 124 square miles, is the largest island in the new country. The total land area of Kiribati is 264 square miles scattered across two million square miles of Pacific Ocean.

5N0DOG is Dave Guthrie, formerly K4QX/5N0. Dave's setup there in Nigeria includes a TS-820, an Alpha linear, and a TA-33 up 60'. He also has SSTV equipment and has promised unlimited activity. Dave has moved around quite a bit, having formerly signed HS1ADV, OX3BQ, KG1FR, KG6AOU, KL7ARL, TF2WBV, and KC6BO, to name a few. QSL to W4FRU, 4640 Ocean View Avenue, Virginia Beach VA 23455. SASE, of course.

Slim recently advised us of his *upcoming* itinerary. He will be signing RG8U from the Belden Congo (QSL to C0AX), and then is off to the Indian Ocean where he will be signing FR0ZE with C0LD handling the confirmations. I hope you will be able to add these new ones to your list.

The nonprofit Northern California DX Foundation elected new officers recently and the results were as follows: President—John Troster W6ISQ, VP—Bob Ferrero W6RJ, Secretary—Merle Parten K6DC, and Treasurer—Vince Chinn. Don Schliesser K6RV, who has headed the Foundation for several years, stepped down as President but will continue on the Board of Directors.

Lem Nash WA4YVG, who previously signed /VQ9 and VQ9IN, is now signing /KH2 and has settled in for an 18-month stint on Guam. Any of these calls can be QSLed via W4XQ, 102 Schoolfield Drive, Danville, Virginia 24541.

The following bit of editorial comment was recently making the rounds on twenty meters. You CW types will probably have to explain it to your SSB brothers. "DX lists, DX lists, DX lists, RAH. Three dits, four dits, two dits, DAH."

W1OUN was in India recently and visited the Bangalore Radio Club. He reports that hopes there still run high for some possible Laccadive action before the year is out.

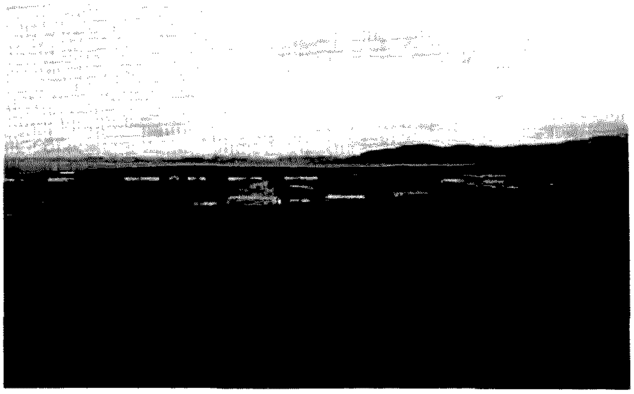
IG9BVS and IG9DMK were on Lampedus Island. QSL to I2BVS and I2DMK.

8J3ITU ran off some 20,000 contacts during ITU week. The QSLs are oversize and will be going out via the bureau. If you're in a hurry, you might try sending a large SASE to JH3DPB.

From time to time you will hear an overseas station complain that IRCs are not accepted in his country. Just because a post office clerk does not recognize an IRC, it does not mean they are invalid there. IRCs are legally good in all countries, with no exceptions. If you are having problems getting IRCs accepted, write to the local postal authorities. Do not take the word of a minor window

Continued on page 152

Kris FB8XV and his station on Kerguelen Island. Kris has handed out many new country contacts from this rare QTH.



Scenic view of lush Kerguelen Island. FB8XV says there is no lack of feminine companionship as there is a girl behind every tree.

LETTERS

INTERESTING METHODS

The article by Jerrold Swank W8HXR, "Compact Beams for 20 or 15," in the July, '79, issue provides some interesting methods of compacting HF beams.

Swank's method of feeding, however, may cause considerable exasperation to anyone who attempts to duplicate his results, or who picks up the tidbit about using a quarter wavelength of RG-59/U as a quarter-wave transformer providing a 2:1 step-up ratio and later attempts to apply the principle to a similar feed problem.

Swank states, "I used a quarter wavelength of RG-59/U as a matching section from the driven element to the RG-8/U coax lead-in. I guessed that the beam impedance would be about 20 Ohms, and this would raise it to 40 Ohms."

His first guess was probably close, but his guess about what the quarter-wave RG-59/U matching transformer would do missed by a country mile. The 20-Ohm feedpoint agrees closely with published data in several books by Orr and the *ARRL Antenna Book*, where driven element-to-director spacing approximates 0.11 wavelength spacing. Swank's 20-meter beam with an 8-ft. boom would provide this condition.

However, a quarter-wave matching transformer of RG-59/U (73 Ohms), will only provide a 2:1 step-up ratio where Z_S = 106.07 Ohms and Z_R = 53.035 Ohms. These conditions are not met, since he estimates Z_R to be 20 Ohms.

Given that his feedpoint resistance does, in fact, conform to textbook data, what his quarter-wave matching transformer of 73-Ohm coax will do is transform the 20-Ohm Z_R up to 266.45 Ohms, presenting then a 5.124:1 mismatch to the 52-Ohm RG-8/U feeder.

This can be proven mathematically by the standard quarter-wave transformer equations: $Z_S = Z_O^2/Z_R$ and $Z_O = \sqrt{Z_R Z_S}$, where Z_O = characteristic Z of line, Z_R = resistive termination, and Z_S = input Z of the line.

From the equations, we can also calculate the correct Z_O to provide the desired match between 20 Ohms (Z_R) and 52 Ohms (Z_S), the nominal Z of the RG-8/U feeder. For these impedances, the Z_O should be 32.2 Ohms, which is not a standard coaxial line. It can, however, be accomplished by using parallel quarter-wave sections of RG-59/U or RG-59B/U, connecting both braids and both center conductors in parallel. This will provide an equivalent line with Z_O of 36.5 Ohms (75 ÷ 2), a value close to the ideal. To calculate the mismatch into the RG-8/U using such a transformer, it is necessary to refer again to the equation: $Z_S = Z_O^2/Z_R$; Z_S = 66.6 Ohms.

Impedance mismatch between the RG-8/U (52 Ohms) and the quarter-wave transformer Z_S (66.6 Ohms), being a function of the ratio of these two values, then becomes 1.28:1, obviously a very acceptable value and a substantial improvement over the mismatched condition presented by Swank's quarter-wave of RG-59/U.

This then raises a question about how Swank obtained an swr measurement of 1.5:1 at the lowest point. This would make it appear as though the quarter-wave of RG-59/U was transforming a Z_R of 68.32 Ohms to a Z_S of 78 Ohms, since RG-8/U terminated in a 78-Ohm load would operate with the 1.5:1 swr he indicates. With a parasitic element spaced only 0.11 wavelength from the driven element, a feedpoint resistance of 68.32 Ohms would be much higher than normal, unless the elements were severely detuned. While this is possible, it is much more likely that his indicated 1.5:1 swr is simply incorrect. This can be verified by adding another length of RG-8/U between the feeder and swr bridge. The chances are that the swr will then change, indicating that neither the 1.5:1 value nor the second value obtained present a true picture of what the mismatch actually is.

My purpose in writing this is twofold—first to correct the error in the article, since Swank's assumptions about the quarter-wave transformer were totally incorrect and may lead someone astray, and second, to demonstrate that his original guess of a 20-Ohm feedpoint resistance may also have been in error.

Before applying any method of improving the impedance match, it would seem logical to actually measure the feedpoint resistance. Two of the regular advertisers in *73* offer economical equipment for this purpose: MFJ's MFJ-202 RF Noise Bridge and Palomar Engineers' RX Noise Bridge. Both will indicate feedpoint resistance in addition to the resonant frequency, eliminating the need to "guess" what these critical characteristics might be. To hang a matching system on an unknown feedpoint resistance is kind of like scooping a handful of pennies into a bag, then saying that by removing 20, only 52 will remain.

Robert G. Wheaton W5XW
San Antonio TX

The chances are that my feedline was not a real half-wave multiple. Anyway, the simplest solution would be to use a pair of 59/U coax cables in parallel, which would be 37.5 Ohms. The length required is only about 10' 10", and this would give a match of 1.4:1.

The alternative would be to use no matching section, which would give a match of 2.6:1, and, if necessary, trim the feedline for a match or use a small L network.

I wrote the article mainly to give hams ideas on how to make beams with the materials at hand. I apologize for the error.

Jerrold Swank W8HXR
Washington Court House OH

MINUTES

A little research of the Minutes of the ARRL Board meetings the past six years has turned up a few interesting facts and raised a few questions, all of which might be the subject of a future editorial: expense accounts of the Directors and the President of the ARRL.

Naturally, being in the Hudson Division, I took a look at the expense account of this Division Director. It looks like this:

	Authorized	Increase	Total Received
1979	$4,000.	$(note)	$4,000. + ?
1978	3,500.	300.01	3,800.01
1977	3,000.	204.30	3,204.30
1976	3,000.	none	3,000.00
1975	3,000.	36.23	3,036.23
1974	2,500.	none	2,500.00

Note: The increase in authorization to a Director comes at the Board meeting the following year.

Now, I work for the State of New York, traveling extensively throughout the state (not just the Hudson Division), with an occasional extra trip to Harrisburg PA or to Washington DC. My expenses include lodging, subsistence, plane fare, airport limos, taxis, and car rentals. My expenses for any year haven't come anywhere *near* the Hudson Division Director's expenses authorized for 1974, the minimum of those checked!

Another very interesting fact turns up when looking for the expense accounts authorized to the President. The 1979 Board (1st) meeting authorized Mr. Harry Dannals an amount not to exceed $10,000 "for 1979." Looking at the Minutes again, I can't find *any* authorization for Mr. Dannals for the years 1978 and 1977. (Isn't that strange?) He was authorized $7,500, "for 1976," though. Apparently nothing was authorized for 1975 and 1974. Question: If, indeed, as I suspect, the President *did* receive expense authorizations for the years 1978, 1977, 1975, and 1974, where were they hidden???

The above "gravy trains" are being financed by the membership through an increase in dues in 1977 to $12 a year, and again in 1979 to $18 a year. It is no wonder that they are finding it difficult to increase the membership in the ARRL at these rates.

A most significant item (Minute #74) in the Minutes of the January, 1979, Board meeting, makes me very suspicious of financial finagling in Newington. Mr. Holladay made this motion that the General Manager (Baldwin) be directed to publish the League's audited financial statements in *QST*. This motion was amended by Mr. Price (at whose instigation?) to have the editor of *QST* directed to remind members through "League Lines" of the availability upon request of the League's audited financial statements. The amended motion was adopted, over the opposition of Mr. Holladay.

It is no wonder, with all the "lulus" available, that the Directors and the President are not desirous of rocking the boat by asking for an investigation of blatant dictator management of the ARRL in Newington.

Byron H. Kretzman W2JTP
Huntington NY

SACRIFICE

With mixed feelings, I wish to inform you that, in a drive to cut down my subscription list to something commensurate with my time to read, I am renewing your magazine and sacrificing the comparably laudable *Scientific American* and *Mother Earth News*. Yours has more circuits.

I have successfully resisted becoming a ham for some 35 years, and now that I am partially deaf (the National Semiconductor LM389 makes a dandy hearing-aid amplifier chip, though), it's unlikely that I'll ever succumb. I'm a longtime

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Occasionally, a letter comes in which is so far afield from an idea I was trying to get across that I feel I must have made too many assumptions in the presentation. Such is the case this month.

Pete Buyaki K5GV is having trouble understanding my presentation of hexadecimal arithmetic. Pete writes, "[I] . . . hit a snag when I came to $5F, etc. This seems odd since these numbers are in the middle of the ASCII table, because it's in the middle of the alphabet table . . . Looking up in the ASCII tables:

	$	0100100	
	5	0110101	
	F	1000110	
	$	0100100	Subtracting this
	2	0110010	group from the
	0	0110000	group above
the difference		0000000	space ?
		0000011	ETX (end text)
		0110000	SYN (synchronous idle)

"I'm sorry, but I don't understand the relation as to how the Baudot will remain in the capital letter format when ASCII is putting out lowercase letters."

Okay, Pete, there are two items of note here. First off, the convention representing one eight-bit byte in hexadecimal is "dollar sign—left nybble—right nybble." In other words, 01001110 in binary corresponds to 4E in hexadecimal. So, when I say $4E, what I mean is 01001110. Now, in ASCII, that $4E corresponds to "N". Lowercase "n" is $6E, which is $20 more than $4E. That is, $4E + $20 = $6E. Another way to look at that is by converting the hexadecimal to decimal. $4E is 78 decimal, and $20 is 32. Thus, 78 + 32 = 110, and 110 decimal is $6E hexadecimal.

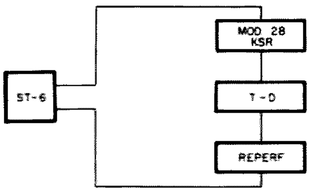

Fig. 2.

If everything is clear so far, I'll throw in one more loop. The ASCII we have been talking about is a seven-bit code, but the hexadecimal representation is eight bits. The most significant bit is frequently called the "parity bit," and we have assumed it is set to zero. Some references assume a parity bit of "1". In that case, add $80 (1000000 binary) to the ASCII values as represented. For example, carriage return becomes $8D rather than $0D, and that "N" becomes $CE rather than $4E.

One final note before I move on. I said that the dollar sign is used to preface hexadecimal numbers. You might wonder if other bases have similar labels. They do! Binary is denoted by a percent sign, and decimal either by no sign or an ampersand. Thus, %01011010 = $5A = &90.

Another item in the mailbag this month is from D. A. Scott W4AKQ in Cape Coral, Florida. Scotty is looking for information on "silent RTTY," that is, RTTY using video terminals or computers. Sorry to say, I know of no book devoted exclusively to the subject. More articles have been published here in *73* than just about anywhere on that topic, however, and Fig. 1 is a compilation of articles I have noted within the last several years. Little information on any of the commercial RTTY video terminals has been received by this column, despite promises and offers from several sources. I would encourage you to ask around your area and see what people are using. Be sure to write the manufacturers of any equipment you contemplate buying prior to investing in a unit, for information and literature. There apparently have been some problems with rf sensitivity and interfacing difficulties with some widely advertised equipment.

Fig. 1. Articles on silent RTTY.

Another note received in the mail is from Art Santella K1VKO in East Norwalk, Connecticut. Art is using a Model 28-KSR Teletype and has added outboard paper tape equipment to provide the features of the "ASR" set. What he wants to be able to do is punch a reply tape while receiving.

I presume that you have the common Model 14 tape equipment, Art, although this will apply to any standard equipment. The tape punch you have is called a "reperforator," because it punches off of an active TTY line. Data is fed into it via the standard 60 mA [R]TTY Loop (don't mind the plug!). From what you tell me, you are using a HAL ST-6 demodulator as both the source of data and the loop supply. I assume your station hookup is something like Fig. 2.

There are many ways of hooking equipment up together, switches, tie lines, and the like, but the way that many RTTY enthusiasts have come to love over the years is with a patch panel. Diagrammed in Fig. 3, this is a series of phone jacks which are connected in series, so that any equipment plugged into the strip is in series with anything else. Equipment may thus be switched from loop to loop with a minimum of effort. The key to the system is that the jacks are all shorted if nothing is plugged in. Thus one jack or all may be in the system at any time. Such a plug/jack system may be just what you need.

If you look into your Model 28, you should find a terminal strip, diagrammed in RTTY Loop, October, 1978, page 20, upon which are represented the leads for the keyboard. You should find a black and a brown wire on terminals seven and eight of TB-751. Bring these wires out to a plug and the terminal connections to a shorting jack. When you plug the keyboard leads into this jack, all will be as original. However, when you plug the keyboard into an auxiliary loop, which also supports the reperforator, you will be able to punch tape independent of the printer. Fig. 4 diagrams this system.

If you are going to do this, be sure that your keyboard contacts are clean and bypassed for rf. You normally do not receive while typing, and thus are unaware of the arcing that takes place on many keyboard contacts. If not conditioned, this arcing can generate severe hash in the received signal. A simple loop supply to use to run the auxiliary loop is shown in Fig. 5. Please don't forget that current-limiting resistor. Fried selector magnets do not smell very good.

That's about it for this month. With autumn approaching, conditions should be changing on many of the HF bands, and I hope to be on more and QSO many of you who have written.

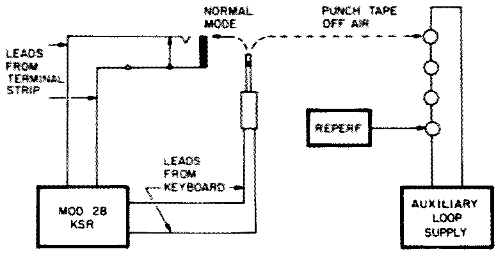

Fig. 4. Sample station wiring.

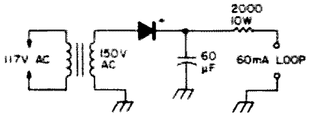

Fig. 5. Simple loop supply.

New Products

SON OF THE QF-1

The recently introduced Autek Research QF-1A active audio filter is a unique selectivity-enhancing accessory that should be of interest to many amateurs, not only because of its quality and features, but also because of its moderate price tag ($65 at this writing).

The QF-1A is the latest in a line of receiving filters that Autek has marketed since 1972. One could probably trace the lineage of the QF-1A and its competitors to the popular National Radio "Select-o-Ject" audio filter that was the apple of many a ham's eyes in the fifties. The current breed of solid-state filters offers a lot of improvements over the "S-o-J" and its vacuum tubes; the QF-1A, I found, has a number of special features that make it of great interest to CW and SSB operators alike.

Among these features are four filter modes of operation (peak, notch, lowpass, and highpass), continuously variable selectivity or bandwidth from "flat" down to 20 Hz, a main frequency adjustment that can be set anywhere from 250 to 2500 Hz in any of the four modes, and a *second* notch frequency adjustment control (added since the QF-1—more on this feature later). The filter is housed in a 6½" × 5" × 2½" gray-finish case and is designed to be plugged into the headphone or external speaker jack of the transceiver or receiver with which it is to be used. It contains a well-filtered 115-V ac power supply and a one-Watt audio power amplifier, so it does not require any additional connections to the rig for power or audio tap-in.

I have used the earlier QF-1 model filter for more than two years and have found it to be an essential station accessory—and, I might add, one which has required no maintenance at all. And, despite the reasonably sharp 600-Hz CW and 2400-Hz SSB i-f filters which my Tempo 2020 has built in as standard equipment, I have found that the QF-1 has made the transceiver's selectivity a great deal sharper. The continuously variable filter characteristics allow a much greater flexibility in combating QRM and in eliciting "armchair copy" in an extremely crowded band.

The original QF-1, written up in *QST* in March, 1977, is similar in design to the newer version but is simpler and has fewer front-panel controls. The QF-1 has selectivity and frequency controls, a three-position mode switch, a speaker/headphone jack, and an ac on/off switch. The QF-1A, apparently drawing on user suggestions and throwing in some "nice to have" features, has five switches and controls on the front panel: (1) an ac on/off switch, which automatically bypasses the filter when turned off; (2) a four-position mode switch; (3) a calibrated selectivity control; (4) a frequency control; and (5) an auxiliary notch frequency control. The headphone/speaker jack is now mounted on the rear panel.

After unpacking the QF-1A from its shipping carton and reading the instructions (which were carefully prepared and complete), I hooked the unit up to my 2020, replacing the faithful QF-1. I found that overall performance was similar, although audio quality was somewhat "cleaner." Like the QF-1, the filter allowed superior "single-signal" reception of very closely spaced CW stations. The filter also worked nicely on SSB, having a very definite impact on signal readability by reducing sideband chatter, static crashes, background noise, and receiver hiss. By using the adjustable notch feature, heterodynes (beats) could be reduced or eliminated on both CW or SSB with no trouble.

Autek's QF-1A.

So far, there was little difference between the units. I found, however, that the newer filter provided a few operating features not found in the QF-1. For example, the on/off switch now automatically bypasses the filter when it is turned off. When using the QF-1, you had to unplug the speaker or headphones and plug them back into the transceiver or receiver when you were not actually using the filter, a minor but not insignificant annoyance. The older model's controls were adjustable over a comparable frequency range, but they were not calibrated; the QF-1A's controls are calibrated at key points, a factor which is useful in resetting the filter to the "flat" position when casually tuning the band or in trying to remember "which way to go" with a control in a pileup. The controls also have a somewhat improved "feel" and bandspread. The auxiliary notch control even allows a second heterodyne to be nulled out should the occasion arise (it will!). It's also possible to use this auxiliary feature to combine operating modes so that you can simultaneously notch/peak, notch/lowpass, or notch/highpass to your heart's content; the instructions tell just how to set up the controls to perform all this "black magic."

The new filter, I found, really comes into its own in serious CW work under crowded contest weekend or DXpedition conditions where weak, in-the-grass signals can often be brought up to effective "599" levels even in the presence of close-by rock-crushing signals which would ordinarily obliterate them. The desired signal can be peaked with an effective bandwidth of as little as 20 Hz with minimal ringing (although such narrow bandwidths are not usually necessary and can be fatiguing to the operator). Using the notch mode, very pronounced rejection (up to 70 dB) can be attained with very little tinkering with the controls. I find that operating in the lowpass mode doesn't produce excessive "booming" and is perfectly adequate for casual CW work used in tandem with the Tempo's 600-Hz filter. When the QRM gets rough, I switch to the peak mode and use the selectivity and frequency controls to zero-in on the desired signal. It's interesting to note that even with the transceiver's sharp CW filter, it's possible to actually "tune through" the Tempo's 600-Hz bandwidth and bring up three or four *separate* CW signals to solid copy that were unreadable without the filter in the circuit.

My use of both filters has indicated that SSB reception is also normally best in the lowpass mode and allows one to easily cope with adjacent-signal splatter and QRM; I like to run with this mode engaged at all times, as it enhances overall audio quality. The auxiliary notch control is effective in nulling out heterodynes, and when the SSB sledding gets rough, all one has to do is to slightly "sharpen up" the selectivity by tweaking the selectivity and frequency controls.

While the QF-1A and other active audio filters work best with receivers and transmitters that have narrow, steep-skirted internal i-f filters, I have found that the filter also does a surprisingly good job on sets that have poor i-f selectivity characteristics. For example, I found that I could dramatically improve the *effective* selectivity of my Yaesu FRG-7 general coverage receiver. The FRG-7, as supplied from the factory, is much too broad for good SSB and CW work. It's mainly an AM-type SWL receiver, and a good one for that purpose. Its basic i-f selectivity is listed as ±3 kHz at 6 dB down, and a built-in *fixed* audio filter allows selection of either 3-kHz, 2500-Hz, or 1500-Hz bandwidths. When hooked into the QF-1A, I could tell little *practical* difference in overall CW and SSB selectivity characteristics between the FRG-7 and the Tempo 2020 with its excellent internal filters! CW signals which were completely unreadable on the barefoot FRG-7 were now a solid Q-5 copy with the filter switched in, and the improvement in SSB reception, though not quite as dramatic, was nevertheless impressive. Of interest to SWLs, I found that the filter also improved AM selectivity on both the shortwave and AM broadcast bands and allowed stations just a few kHz apart to be separated nicely with little cross-channel chatter. This ability would be of special help to the medium-wave DXer in trying to sort out split-channel AM broadcast stations (those operating between the standard 10 kHz U.S. channels), as well as foreign broadcast stations which are often but 3 or 4 kHz apart on the shortwave bands. (If you use the QF-1 with the FRG-7 or another receiver with a built-in fixed audio filter, run with the internal filter *out* for best results.)

Being an inquisitive sort, I tried out the new filter with some other equipment and was surprised by the results. For example, I used it quite effectively with a converted Johnson 4740 SSB transceiver on ten meters. When operated in the

lowpass mode, the filter did a great deal to reduce channel "bleedover" effects and crosstalk. Also, the notch feature was handy in suppressing annoying heterodynes from the many AM stations now on the band that use converted AM CB transceivers.

I also experimented with the filter on my KLM-2800. The 2700 is designed for two meter all-mode work, though the primary emphasis—as in most other "all-mode" transceivers—is on FM; it is somewhat lacking in good CW selectivity, and there are no provisions to add optional i-f filters to reduce bandwidth. Hooking up the QF-1A had much the same beneficial effect as it did when it was worked with the Tempo 2020—only more so. The filter added a great deal of selectivity to an otherwise broad set for serious CW work, and it made a difference on SSB as well. As expected, it didn't do much for FM reception.

The original QF-1 design was a good one. Most of the QF-1A's changes are convenience features and minor improvements, such as the addition of the automatic bypass, the auxiliary notch control, and the calibration marks on the selectivity/frequency controls. Also, the newer version's selectivity goes down to 20 Hz, as opposed to a "mere" 50 Hz on its predecessor. Both designs are thoroughly bypassed and filtered to prevent rectified rf from your transmitted signal from getting back into the audio circuitry and causing problems; I had no difficulty from rf feedback even when running a full kilowatt on 80 through 10 meters.

When working with very narrow selectivity, you may find it convenient to connect a Y-cord adapter in the output line and run an output to an oscilloscope or ham-type monitorscope (such as the Heath SB-610 or similar Yaesu and Kenwood versions) to visually help in determining exact audio peaking. Also, one feature that could have been added to the QF-1A but wasn't is a set of switches to allow its use with two audio sources (two receivers, or a transceiver and a receiver) and two outputs (a headphone and a speaker). As it stands now, the unit must be manually plugged in and out of the equipment with which it is to be used, and the speaker and headphones must be plugged and unplugged by hand.

Also, I have found it expedient to feed the filter's output to a small "wireless FM rebroadcaster" module (I use the Ramsey module @ $3) used in conjunction with a pair of cordless FM headphones. Doing so eliminates the need for clumsy headphone coiled cords and has the side benefit of allowing you to monitor the band anywhere in your home or yard by tuning in the rebroadcaster's signal on a nearby FM radio. You may not want to try this, but I mention it to point out the possibilities and advantages of hands-off, cord-free hamming.

Some suggestions I had for enhancing the versatility of the basic QF-1 were described in my May, 1978, *73 Magazine* article, "The Super Select-o-Ject." Many of the changes I made to the QF-1, such as the switching arrangement, can be adapted to the new filter.

One caution: The QF-1 and its successor tend to emphasize any residual ac hum present in the transceiver's or receiver's audio output. This is normally caused by insufficient ac filtering in the rig and not in the audio filter. I have found this condition to be noticeable mainly when operating in the lowpass mode and feeding low-impedance, hi-fi type headphones, which normally have a heavy bass response. This problem can be minimized by adding a 50-to-150-Ohm, ½-Watt resistor in series with the headphone lead to cut down the phones' sensitivity and low frequency response.

In my opinion, the QF-1A is a real jewel well worth the modest price tag. While I have not as yet made an in-shack comparison between the Autek filter and its competition, I can say that the quality of construction (steel case) and circuitry board is excellent and reflects care in design and manufacture. The QF-1A makes a modest receiver or transceiver "come alive" in the selectivity department and allows the average set—so often lacking in *real* CW performance—to become a winner. For further Information, contact *Autek Research, Box 5127, Sherman Oaks CA 91403.* Reader Service number A100.

Notes

1. There are a large number of audio communications filters on the market today. These include some highly competitive designs by MFJ, Waneco Radio, Dynamic Electronics, Datong, Kantronics, Electronic Research Corporation of Virginia, and others. These filters range in price from about $30 to $200 and more. If you are interested in building your own, a very good active filter design is shown by Donald Morar W3QVZ in the December, 1978, issue of *73*. His article, "Build the Flexi-Filter—A Very Active Device," is on page 222.

Non-Linear System's MS-215 Miniscope.

MISSION IMPOSSIBLE? NOT WITH THE MS-215!

The manufacturer's service information reminded me of that TV series "Mission Impossible," and for that matter, what I had to do could very well have been a script for the show. It was nothing exciting—I just had to identify one bad chip on a circuit board containing 36 chips, located in a cabinet with an access door about 18 inches square. But, not to worry, according to the manufacturer—just get into the cabinet with a dual-trace 10-MHz scope, triggered, and look for the inputs and outputs on each chip. When you don't find both conditions, you've found the bad chip. I did omit one minor consideration—the board was a part of a computer-based central station monitor at our hospital, was hardwired in, and had to remain operational during the entire test procedure.

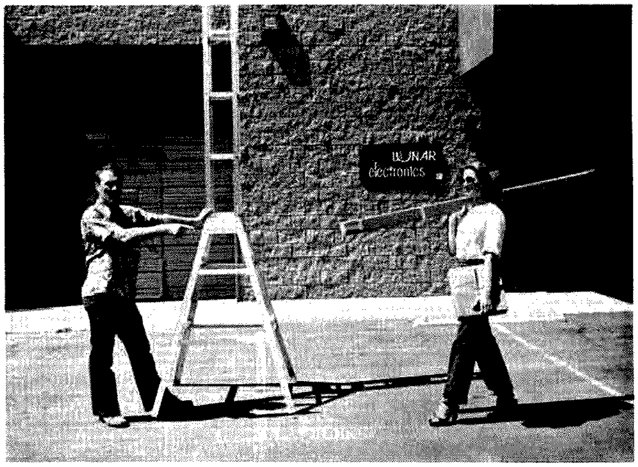
Not to be thwarted, I reached into my tool set and removed just what the "doctor" ordered, the Non-Linear System's MS-215 15-MHz dual-trace scope. Besides being self-contained and self-powered by nicads, the Miniscope measures a mere 2.9" x 6.4" x 8.0". Its vertical bandwidth extends from dc to 15 MHz, with ac, dc, or ground coupling switch-selectable. Deflection is 10 mV/div to 50 V/div in 12 calibrated ranges (with a stated accuracy of 3% of full scale with the vernier in the full clockwise position). The horizontal characteristics include: internal timebase or external horizontal switch-selectable mode with a timebase of 0.1 usec/div to 0.5 sec/div in 21 calibrated ranges. The maximum input voltage for both horizontal and vertical sections is 350 V dc and peak ac, providing that the dc component does not exceed 250 volts. A switch-selectable trigger permits + or −, with modes of internal, external, and line (line is non-functional when operating off the nicads). A trigger-level control permits continuous adjustment of the trigger point.

While all of these technical specifications will impress a number of you, why should you or any ham want a scope this tiny? The answer is quite simple: The MS-215 Miniscope can go to the work when the work can't go to the scope! Maybe that's an oversimplification of the issue, but how many times in the last six months have you wished that you could have a piece of test equipment which was scaled down in size to the IC circuitry being examined, be it a computer CPU or the innards of a synthesized 2-meter ham rig? Better yet, how many jobs could you have done with little or no sweat if you and your scope could have been right there—on the spot rather than tied to a large scope with equally large probes further hindered by an ac power cord.

I acquired an MS-215 because with it we could locate the defective chip and remove and replace it at a total cost of perhaps $2.00 in parts, while the new board would have cost somewhere in the area of $1200. Considering that the MS-215 sells for around $400 from a number of advertisers in *73*, purchasing it was a very wise move in terms of dollars and cents!

What can't you do with the MS-215? Well, to be honest, very little—unless you want to display a waveform to more than two close friends. We have literally used the scope for everything and anything you could imagine—from probing the interior works of a piece of hospital gear to troubleshooting the somewhat sickly departmental HT. In all cases, it performed as well as one of the larger and considerably higher-priced scopes in the department. Considering that the small package even included a calibrator which provides a square-wave signal of 1 volt peak-to-peak, and a graticule

Nye Viking's Model 250-0046-001 phone patch.



Lunar's LT-1 modular tower.

which (while small like the CRT) is easy to read—what more can you ask for in a package you can comfortably stuff into a coat pocket?

If you are interested in what you've read thus far and want more information about the MS-215 Miniscope, drop Mr. Allan Kay a line at *Non-Linear Systems, Inc., Dept. 73, Box N, Del Mar CA 92014.* Be sure to tell him that you read about their products in *73 Magazine*. Reader Service number N22.

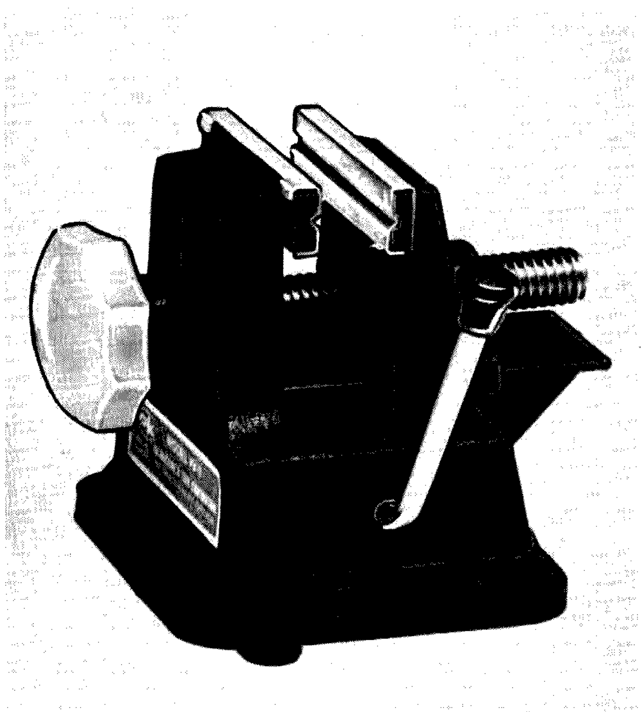
NYE VIKING RECEIVES FCC REGISTRATION FOR PHONE PATCH

Approval by the Federal Communications Commission for official registration under Part 68 of the FCC Regulations has been granted to the Wm. M. Nye Company, Bellevue WA. This allows the Nye Viking phone patch to be plugged directly into the telephone line without the need (or cost) of a telephone company-supplied coupling device. It should be noted that users must still notify the telephone company that they are connecting the phone patch to the telephone line, and must furnish the company the official registration number and the ringer equivalence number (which are printed on an attached label).

Telephone patches may not legally be connected to party lines or pay telephone lines. Users are cautioned that they must comply with all other requirements of the FCC pertaining to amateur radio communications.

The Nye Viking phone patch comes in two models: the 250-0046-001, without speaker, which provides connection to your own external speaker, and the 250-0046-003, with built-in loudspeaker, for use with most transceiver installations.

Nye Viking phone patches manufactured prior to official FCC approval and registration can be upgraded to approved status with the necessary changes, which include a 7-foot cord and a plug to connect into the telephone company line socket. Units returned for modification should be carefully packed and contain the sender's name and address. For further information, contact the *Wm. M. Nye Company, Inc., 1614 130th Ave. NE, Bellevue WA 98005.* Reader Service number N4.



OK Machine and Tool's new VV-1 vise.

LIGHT-DUTY VISE

The new Model VV-1 from OK Machine and Tool Corporation is a unique vacuum-based light-duty vise for precision handling of small components and assemblies. Featuring rugged ABS construction, it has 1½" wide jaws and 1¼" travel for maximum versatility. Also featured are an oversize knob for precise positioning and screw lugs for permanent installation. For further information, contact *OK Machine and Tool Corporation, 3455 Conner Street, Bronx NY 10475.* Reader Service number O5.

LUNAR'S MODEL LT-1 MODULAR TOWER

Lunar Electronics has announced a new line of towers. Manufactured in Lunar's San Diego plant, these towers are all-aluminum angle pieces, which bolt together to form a sturdy structure capable of supporting considerable antenna arrays. The modularity of the six-foot sections makes them a natural for site surveys, field operations, and portable communications tests of all sorts, including amateur radio EME (moonbounce) operations.

Taking advantage of a building's height, they readily mount on rooftops, flat or peaked. The use of a length of 2 x 4 under leg pairs provides a simple yet effective mount for the tower. Since it must be guyed, no bolts, nails, or other requirements are necessary. The 2 x 4s additionally serve to distribute the weight over several roof joists.

These portable units are readily UPS shipped, and may also be carried as luggage on any airline. The construction is not unlike a childhood toy erector set, with each module bolted together with supplied hardware. Optional stainless steel hardware is also available (S suffix). Rotor and thrust bearing mounting plates are included in the basic tower package (Model LT-1), which yields an 11-foot structure when erected. The 6-foot add-on modular sections (Model LT-2) increase the height up to nearly 30 feet.

Since the tower is built from angle pieces, it forms its own ladder when erected and guyed. The base is 43 inches square, and the tower sections are 9.5 inches square. For further information, contact *Lunar Electronics, 2785 Kurtz Street, Suite 10, San Diego CA 92110; (714)-299-9740.* Reader Service number L17.

Microcomputer Interfacing

Peter R. Rony
Jonathan A. Titus
Christopher A. Titus
David G. Larsen

MULTIPLEXED LED DISPLAY

Regardless of their application, most microcomputers need peripheral I/O devices for the input and output of data. The more common output devices included seven-segment displays, 5 x 7 dot matrix displays, teletypewriters, and cathode-ray tube (CRT) displays. We shall discuss several methods that can be used to interface seven-segment displays, as well as several different programs that are typically used to "drive" such displays, which are widely used in electronic games, calculators, point-of-sale (POS) terminals, gasoline pumps, children's toys, and taxi meters.

One of the simplest methods that can be used to interface a seven-segment display to a microcomputer consists of latching the appropriate data values from the data bus under software control (Fig. 1). The latch's inputs (7475) are wired to the microcomputer's bidirectional data bus and the latch's outputs are wired to a seven-segment decoder/driver (7447). The decoder's outputs (current sinking) are wired to the seven-segment display with 220-Ohm current-limiting resistors. When an OUT 125 instruction is executed, the content of the 8080's A register is latched by the display interface and the two BCD numbers represented by D7-D4 and D3-D0 are illuminated on the two displays. The instructions listed in Fig. 2 cause a 39 to be displayed.

To display a 10-digit number using this method, ten latches, ten decoder/drivers, seventy resistors, and ten seven-segment displays will be required. One method of reducing the "parts count" for this interface would be to use a device such as the 8255 Programmable Peripheral Interface (PPI) integrated circuit.[1] This device can be used as three independent eight-bit output ports, so it is the equivalent of six 7475 latches. Therefore, two 8255 PPI chips, along with 10 decoder/drivers, seventy resistors, and ten seven-segment displays would be required in the interface. One obvious disadvantage of this interfacing method is the large number of integrated circuits required. However, one advantage is that the software required to drive this interface is relatively simple. Also, the microcomputer only has to output this information once to the interface for the information to be continuously displayed. This, of course, is due to the latches or the 8255 chips in the interface. Thus, the microcomputer can output numeric information once and then go on to perform any other required operations.

Another interfacing method that can be used is digit *multiplexing*. Multiplexing reduces the display interface electronics (number of parts) to a minimum, but at the expense of longer and more complex display driver software. Multiplexing a display consists of enabling or turning on one particular digit with a *digit enable code* and providing the BCD numeric information for that digit to a multi-digit display interface. In this way, each digit is turned on, one at a time, as the actual BCD data for each digit is provided. Multiplexing is usually only used with multi-digit displays. As an example, suppose that the number 237 is to be displayed on a three-digit multiplexed display. To display this number, the BCD value for the digit seven would be output to the interface, along with the digit enable code for the right-hand display. After a short period (1 to 10 ms), the BCD value for the three would be output, along with the digit enable code for the middle digit. Again, after a short delay, the BCD value for the two and the digit enable code for the left-hand display would be output to the interface. By performing this sequence fifty or more times *every* second, each digit in the display *appears* to be on *all of the time.* This same display method is used in hand-held calculators. Even though the digits are being turned on and off, it is happening too fast for the eye to see. The interface for a 10-digit multiplexed display is shown in Fig. 3.

When an OUT 125 instruction is executed, bits D3 through D0 of the A register will determine which one of the ten digits in the display will be enabled (turned on). Therefore, these four bits constitute the digit enable code. Bits D3 through D0 are latched (7475) and are decoded with a one-of-ten decoder (7442). The decoded outputs of the 7442 are wired to the common cathodes of the individual digits in the display. Bits D7 through D4 will provide the BCD code of the value to be displayed (0 through 9). These bits are also latched (7475) and are decoded by a seven-segment decoder/driver (DS8857, National Semiconductor Corporation, Santa Clara CA). The DS8857 supplies the current required to turn on the various segments (A-G) within the enabled digit selected by the 7442 decoder chip.

A relatively simple program can be written in which five packed BCD words (two BCD digits per word) are output to the display so that a 10-digit number is displayed (Fig. 4). This program has to unpack the BCD words stored in memory, combine the BCD digits with a

Awards

Bill Gosney WB7BFK
2665 North 1250 East
Whidbey Island
Oak Harbor WA 98277

After months of planning and careful consideration, I'm particularly proud to announce this *73* exclusive—*the 73 Magazine Awards Portfolio.* Consisting of four domestic award incentives and four DX achievement programs, the awards portfolio promises to be a challenge and capture the interest of almost everyone on the band, whether you are a casual rag chewer or a big-time contester.

Read through the various award rules with caution. The requirements are not as easy as one might first imagine. We want our award recipients to know they had to earn their recognition and therefore designed each award to be somewhat of a challenge.

I will present each award in detail—the DX-oriented awards will be in the spotlight this month, and next month I will focus on the domestic ones.

Each of the sponsored awards will offer its own degree of difficulty. None was designed to be an overnight accomplishment, nor were any meant to duplicate any other awards in existence today.

So tune up those QRP rigs, kick in the blower on the kilowatt, rotate those beams, and fine-tune that dipole, as time's a wastin'; you've got some contacts to make and some awards to win! I plan to feature a special profile of the winner of the first award issued in each category. Subsequent recipients will be recognized in a monthly award summary.

73 DX COUNTRY CLUB AWARD

1. Sponsored by the editors of *73 Magazine.*
2. Available to licensed amateurs throughout the world.
3. To be valid, all contacts claimed must be made in a *single calendar year* (January 1 through December 31), beginning January 1, 1979, and after.
4. This award is available for all phone, CW, and mixed modes.
5. To qualify, a minimum of 73 DX countries must be worked and confirmed from the *73 Magazine* WTW (Work the World) DX Listing. All contacts must be made in the same calendar year.
6. Annual endorsement stickers are available for each succeeding year in which a minimum of 73 DX countries are worked.
7. To apply, prepare a list of claimed contacts in prefix order. Include each station's full callsign, date and time in GMT, mode, and band of operation.
8. Do not send QSL cards! Have your list of contacts verified by two local amateurs, a local club secretary, or a notary public.
9. Enclose your verified list and award fee of $3.00 or 8 IRCs for each award or endorsement. Send to: Bill Gosney WB7BFK, *73* Awards Editor, 2665 North 1250 East, Oak Harbor, Whidbey Island, Washington 98277 USA.

DX CAPITALS OF THE WORLD

1. Sponsored by the editors of *73 Magazine.*
2. Available to licensed amateurs throughout the world.
3. To be valid, all claimed contacts must be made January 1, 1979, or after. There are no mode or band restrictions.
4. To qualify, applicants must work and confirm fifty (50) different national capital cities located in DX countries shown on the WTW (Work the World) DX Listing.
5. To apply, make a self-prepared list of contacts made in prefix order indicating the station worked, date and time in GMT, band of operation, and the name of the capital city and DX country.
6. Do not send QSL cards! Have your list of contacts verified by two amateurs, a local club secretary, or a notary public.
7. Enclose your application list and award fee of $3.00 or 8 IRCs to: Bill Gosney WB7BFK, *73* Awards Editor, 2665 North 1250 East, Oak Harbor, Whidbey Island, Washington 98277 USA.

TEN METER DX DECADE AWARD

1. Sponsored by the editors of *73 Magazine.*
2. Available to licensed amateurs worldwide.
3. All contacts must be made on the 10 meter band using only channelized converted Citizens Band equipment or similar type commercial units operating a maximum of 15 Watts PEP output. External amplifiers may not be used.
4. To be eligible for award credit, all contacts must be made October 1, 1978, or after, on AM, SSB, CW, or FM. Mixed mode contacts are not valid.
5. To qualify, applicant must work and confirm at least ten (10) DX countries from the WTW (Work the World) DX Listing. Endorsements will be given for 25, 50, 75, and 100 countries confirmed.
6. To apply, make a self-prepared list of contacts claimed, giving the callsign of each station worked in prefix order. Include the date and time in GMT, band, mode, and a brief description of the equipment used in making each contact.
7. Do not send QSL cards! Have your list verified by two amateurs, a local club secretary, or a notary public.
8. Forward your application list and award fee of $3.00 or 8 IRCs to: Bill Gosney WB7BFK, *73* Awards Editor, 2665 North 1250 East, Oak Harbor, Whidbey Island, Washington 98277 USA.

WORK THE WORLD AWARD

To enhance the enjoyment of working DX, the editors of *73 Magazine* take special pleasure in introducing what we feel will be one of the most sought-after awards in existence today—the Work the World Award.

1. Sponsored by the editors of *73 Magazine.*
2. Available to licensed amateurs throughout the world.
3. To be valid, all contacts must be made January 1, 1979, or after. There are no band or mode restrictions. Only DX countries shown on the WTW (Work the World) DX Listing qualify.
4. The ultimate goal of this award program is the Work the World (WTW) Award, signifying excellence in DX communications. However, to qualify for WTW, applicants must first meet the requirements of the six Continental Awards, each of which is a worthy goal in itself.
5. Requirements for Continental Awards: North American Awards—work 13 North American countries; South American Award—work 12 South American countries; European Award—work 12 European countries; African Award—work 12 African countries; Asiatic Award—work 12 Asiatic countries; Oceanic Award—work 12 Oceanic countries.
6. The Work the World Award is issued at no cost to any applicant who meets the requirements of all six Continental Awards. The operator who earns WTW has truly "worked the world."
7. To apply for any of the six Continental Awards, prepare a separate list of claimed contacts for each continent, listing all callsigns in prefix order. Include date, time in GMT, and band.
8. Do not send QSL cards! Have your list(s) verified by two amateurs, a local club secretary, or a notary public.
9. Enclose your verified list(s) and award fee of $3.00 or 8 IRCs for each award applied for. Forward to: Bill Gosney WB7BFK, *73* Awards Editor, 2685 North 1250 East, Oak Harbor, Whidbey Island, Washington 98277 USA.

Throughout this column, reference has been made to the new WTW (Work the World) DX Listing. In order to avoid the impossible task of having to decide what is and what is not a country, the awards editor and the staff at *73* decided to accept the decisions of the national amateur radio societies of the world. Special care has been taken to ensure that no single organization will dictate the criteria used; instead, an accumulative effort by all concerned will be recognized.

Thus, as the basis for all the DX awards sponsored by *73 Magazine*, the official WTW DX Listing will be categorized by continents of the world. Within each continent, DX countries will appear in order of their callsign prefix.

Additional copies of the WTW DX Listing or rules of the various award programs are available on request. Please be sure to enclose a 4½" x 9" SASE with all inquiries. Forward your inquiry to my home address which appears throughout this column.

If DX isn't your cup of tea, then the domestic awards featured next month will interest you for sure.

Keep the cards and letters coming. Your comments concerning this column have been well received and appreciated. Should you learn of an awards program being featured in your city, state, province, or country, please forward this information on to me. Together we can share the many achievements being offered our readers throughout the world.

Contests

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

Please note that with this issue all award and contest announcements are being split into their respective separate columns. Please forward all information directly to the individual responsible for the particular column. Any information sent via **73** *Magazine headquarters in Peterborough NH is only delayed and may not be received by the appropriate editor in time to appear in the magazine. Also, to the organizations sponsoring a contest, don't forget to send an abbreviated copy of the results for possible publication. They will be printed as space permits.*

KENTUCKY QSO PARTY

Starts: 0001 GMT September 15
Ends: 2359 GMT September 16

This contest is sponsored by the Bluegrass Amateur Radio Club. Only one contact per band or mode with each station. No repeater or pre-arranged contacts are allowed. Suggested frequencies are lower edge of General and Novice bands, 2 meter simplex and SSB, and 6 meters.

EXCHANGE:

RS(T), county, and consecutive QSO number; non-KY stations substitute state, country, or province for county.

SCORING:

Score 1 point per QSO. KY stations multiply by number of states, countries, and provinces worked. Non-KY stations use number of KY counties worked. Final multipliers are: 1.5 for all 10 meter contacts between 0200 and 1000 GMT; 2.0 for input of 15 Watts or less; 1.5 for input of 200 Watts or less; 2.0 for all VHF simplex QSOs. Novices or Technicians may take an additional 2.0 multiplier for CW only.

ENTRIES:

Mail logs by October 5 to: Donald Page WD4HPL, 309 Pocahontas Trail, Georgetown KY 40324.

WASHINGTON STATE QSO PARTY

Contest Periods:
0100 to 0700 GMT September 15
1300 GMT September 15 to 0700 GMT September 16
1300 GMT September 16 to 0100 GMT September 17

The 14th annual Washington State QSO Party sponsored by the Boeing Employees' Amateur Radio Society (BEARS) is open to all amateurs. All bands and modes may be used. Stations may be worked once on each band and mode for contact points and more than once each band/mode if they are additional multipliers.

EXCHANGE:

QSO number, RS(T), county or state/province/country.

SCORING:

Washington stations score two points for each phone contact and 3 points for each CW contact, including contacts with other WA stations. Then multiply by the total of different states, Canadian provinces, and other foreign countries worked. All others score 2 points for each phone contact and 3 points per CW QSO with Washington stations and multiply by the total number of different Washington counties worked (39 maximum). There will be an extra multiplier of one for each group of 8 contacts with the same Washington county for all non-Washington stations.

FREQUENCIES:

CW—1805, 3560, 7060, 14060, 21060, 28160.

Phone—1815, 3925, 7260, 14305, 21380, 28580.

Novice—3725, 7125, 21150, 28160.

AWARDS:

Certificates will be awarded to the highest-scoring station (both single- and multi-operator) in each state, Canadian province, foreign country, and Washington county. Additional certificates may be issued at the discretion of the Contest Committee. Worked Five BEARS Awards are also available to anyone working 5 club members before, during, or after the QSO Party unless previously issued. All QSO Party entries will be screened by the Contest Committee for possible awards. The Worked 3 BEAR Cubs Award is also available for working 3 Novice members.

ENTRIES:

Logs must show dates, times in GMT, stations worked, exchanges sent and received, bands and modes used, and scores claimed. Include a dupe sheet for entries with more than 100 QSOs. Each entry must include a signed statement that the decision of the Contest Committee will be accepted as final. No logs can be returned. Results of the QSO Party will be mailed to all entrants; an SASE is not required. Log sheets and summary sheets must be postmarked no later than October 17 and sent to: Boeing Employees' Amateur Radio Society, c/o Contest Committee, Willis D. Propst K7RS, 18415 38th Ave. S., Seattle WA 98188.

89'ers RUN

Contest Periods:
Run #1: Saturday, September 15, 1400 to 1800 GMT
Run #2: Saturday, September 22, 2100 to 0100 (September 23) GMT

The object of this QSO party sponsored by the Sooner Chapter of Ten-Ten International is to collect as many 89'ers' numbers as possible and you do not have to have an 89'er number to enter. All contestants, other than local and charter members, may operate *only one* of the two four-hour runs listed above. Locals and charters will operate both runs. Locals and charters will not be competing for awards. Scoring will be the same as for the 89'er awards, except that contacts with people who have a Ten-Ten number only shall count one point. Send contest logs to WD5CSK by October 31. If you wish to apply for the certificate or any of the advanced awards, separate application must be made directly to WB5TKD. If you would like an information sheet and a list of awards, send an **SASE** to contest manager Ron Reid WD5CSK, 8832 NW 80, Yukon OK 73099. Contest logs will not be returned unless an envelope and sufficient postage is enclosed.

SCANDINAVIAN ACTIVITY CONTESTS

CW: 1500 GMT September 15 to 1800 GMT September 16
Phone: 1500 GMT September 22 to 1800 GMT September 23

Non-Scandinavian stations try to work as many Scandinavian stations as possible. The same station may be worked once on each band during the contest. Only CW-to-CW and phone-to-phone QSOs are valid, no cross-mode. Use all bands, 80 to 10 meters, but only within the following sections: CW—3505-3575, 7005-7040, 14010-14075, 21010-21125, 28010-28125; phone—3600-3650, 3700-3790, 7050-7100, 14150-14300, 21200-21350, 28400-28700 (as legal in your country!). The prefixes used in Scandinavia are: LA/LB/LG/LJ—Norway; JW—Svalbard and Bear Island; JX—Jan Mayen; OF/OG/OH/OI—Finland; OHØ—Aaland Island; OJØ—Market Reef; OX—Greenland; OY—Faroe Island, OZ—Denmark; SJ/SK/SL/SM—Sweden. All these prefixes are geographically not in Scandinavia, but they are considered so for the contest. Operator classes include: a) single operator; b) multi-op/single transmitter; c) multi-op/multi-transmitter. Club stations, even if operated by one operator during the contest, are in the multi-operator class. Multi-op/multi-transmitter entries are to use separate series of serial numbers for each band.

Power Line DXCC (Distant Control Circuit)

—The ac lines are already there . . . why not use 'em for remote control?

Dave Brown W9CGI
RR5, Box 39
Noblesville IN 46060

I must first apologize somewhat for stealing this article's title from J. H. Everhart N2CX. His article, in the August, 1978, *73 Magazine*, was entitled "Power Line DX." But, I did not stop there! I stole even his circuits, almost intact. That, too, I must explain.

My intent is to praise him highly. The original article dealt with control of distant (DX) objects by remote control, via existing 60-Hz lines. He helped me by solving my worst problem in controlling my EME array, located on a tower building some 150 feet (by wire and zig-zag routing) from my basement ham shack. First, I built his circuits, and they worked —very well! Then I decided to lay out a PC board to speed matters up if I wanted more than one copy (I did). And then, I decided to do an article just for the PC boards, just to encourage others to try his methods—using his circuits—which, as I said, work very well indeed.

While laying out the first board and mulling over his idea for remote monitoring of his ham receiver, the way of laying out the PC boards shown in Figs. 1(a) and 2(a) evolved. Figs. 1(b) and 2(b) are just loading diagrams to hasten things along for you.

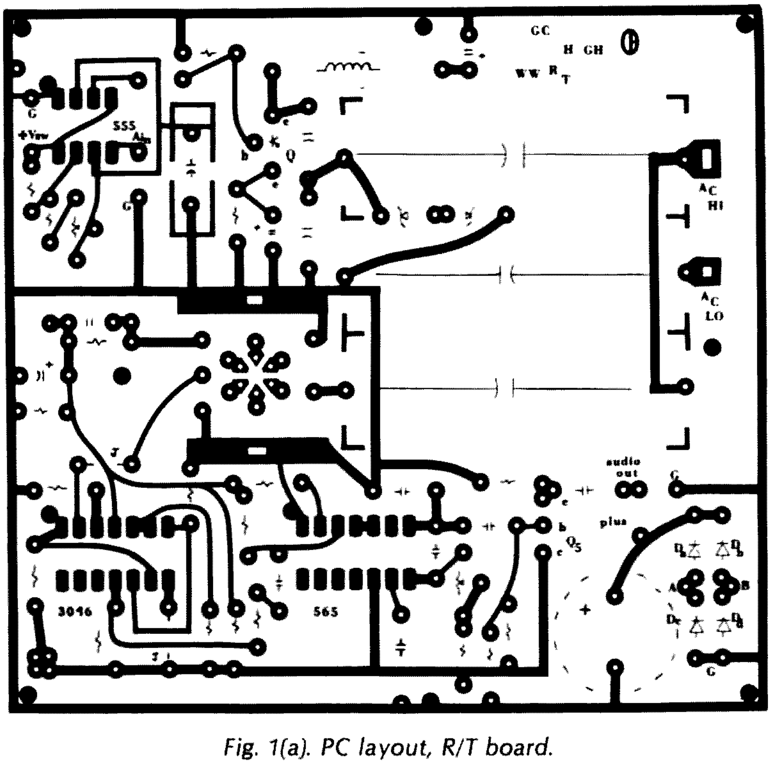

Fig. 1(a). PC layout, R/T board.

Fig. 1(a) is the PC board

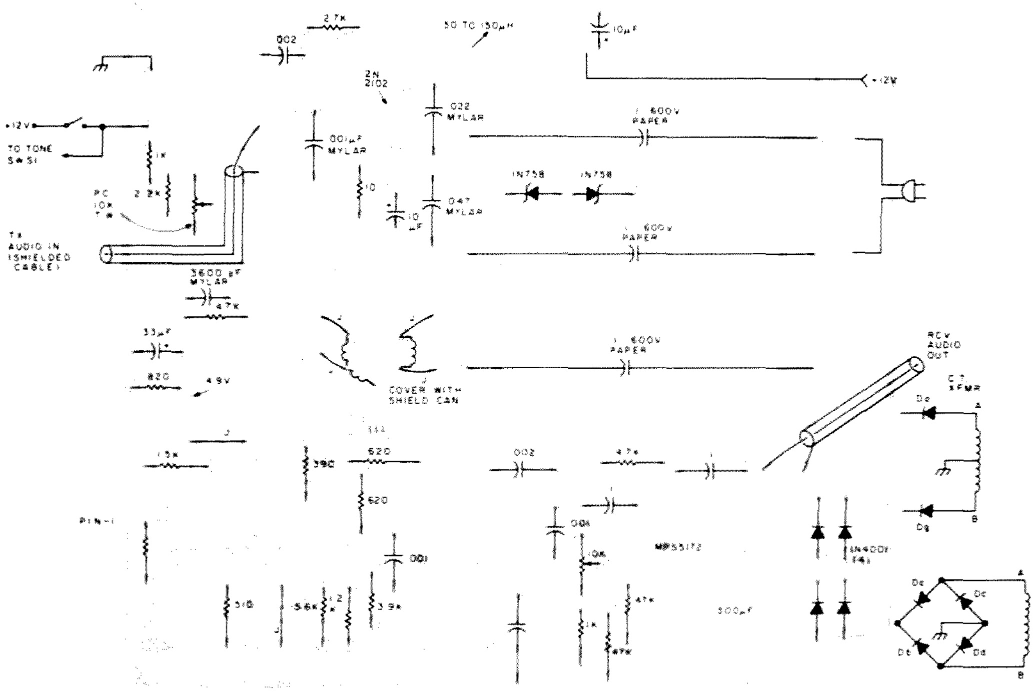

Fig. 1(b). Component layout, R/T board (foil side view).

layout for both transmitter and receiver, or what I call the R/T board. This is the heart of the system to allow hooking up to your power lines. Fig. 2(a) shows two boards—one that accepts up to three CD 4001 ICs and the components needed to handle the generation of up to six control tones (audio), and a second board that can be split up the middle. (See the vertical black line that appears to do nothing electrically.)

The left half of this layout is the audio amplifier (follower, really) and

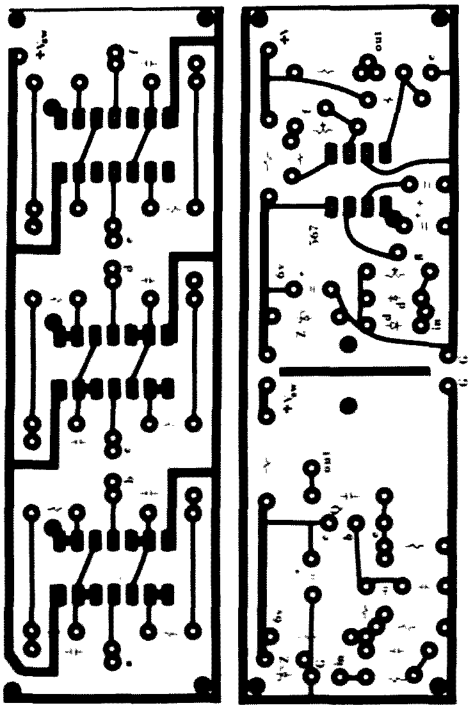

Fig. 2(a). PC layout, tone generator and audio amplifier/decoder-buffer boards.

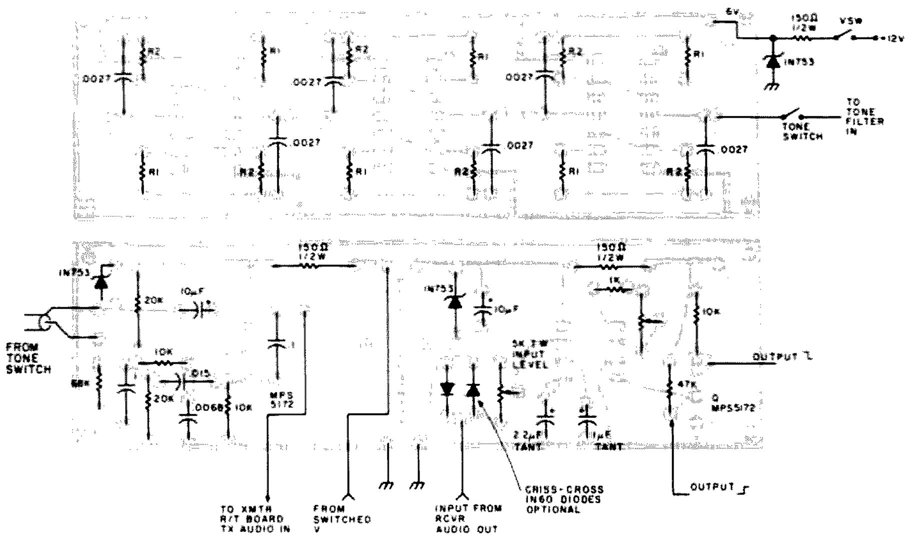

Fig. 2(b). Component layout, tone generator and audio amplifier/decoder-buffer boards (foil side view).

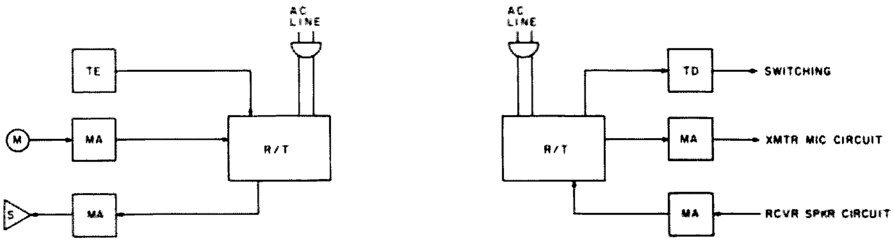

Fig. 3(a). M = microphone. S = speaker. MA = amplifier and matching transformer, if required. TE = tone encoder. TD = tone decoder. R/T = receiver/transmitter board (Fig. 1).

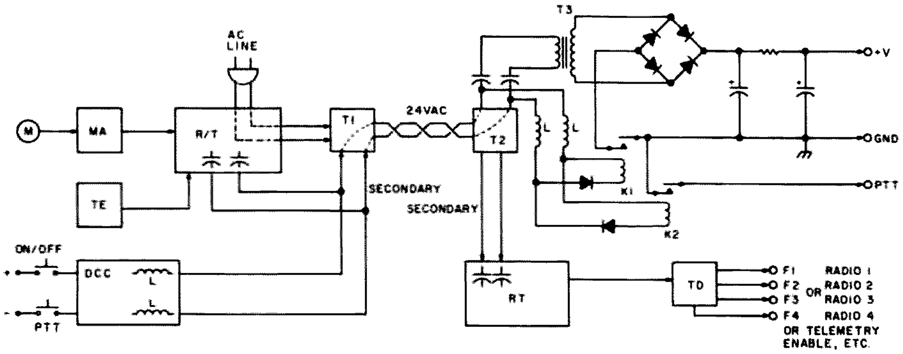

Fig. 3(b). DCC = dc control unit (as required).

X #	Tone	X #	Tone
L 1	69.7 kHz	H 1	120.9 kHz
L 2	77.0 kHz	H 2	133.6 kHz
L 3	85.2 kHz	H 3	147.7 kHz
L 4	94.1 kHz	H 4	163.3 kHz

Fig. 3(c).

the low-pass filter to follow the tone generators. It is shown as an MPS5172 in Everhart's article, Fig. 2, page 53. The right half of the board is all the circuitry to decode and/or buffer/invert a received tone. It is the same type MPS5172 (Q6) and NE567 shown in his Fig. 5.

Once these Figs. 1 and 2 of my PC layout have been done in the photo negative stage, they may be cut apart and boards made in any combination or quantity. The PC board layout removes all the headaches and a lot of the work of this job, so I hope more of you will try N2CX's ideas.

I planned Fig. 1, the R/T board, as a transceiver-type item, because I, too, would like to be able to monitor gear in the ham shack while I am in other parts of the house. I thought it would be nice to be able to have it a two-way circuit, as I'm sure many hams would. The end result of my efforts can be built into a small, attractive case with a carrying handle on it. This allows use anywhere in the house or outbuildings where there is a wall outlet.

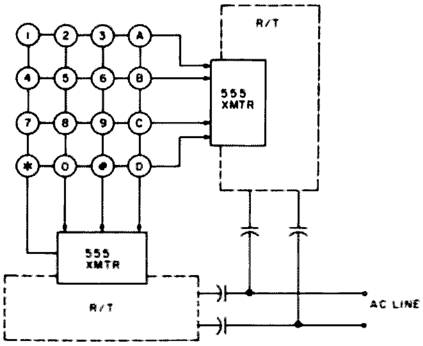
Build up two complete R/T units like that and you have one wireless intercom that can be carried about from room to room and plugged in, while the second unit babysits your child or your ham gear for you. The R/T board contains all the necessary components to take audio in and give rf output ready for, and attached to, the power line in transmit—and the same in reverse, in receive. All that is needed in addition is some obvious switching and an audio amplifier. This would boost up a microphone level that is too low (1.4 V required at the NE555 input) and a received audio that may be lower than you want. Then get the speaker and microphone of your choice.

I got around the latter by using an older Motorola speaker-microphone in one unit, with a coiled cord like those used on the FM handie-talkies. Use the small transformers shown to match up impedances where and when required by what you use. My audio amplifier was a 1- to 2-Watt per channel, with one IC that you often see in a child's record player of the less expensive variety.

To give you an example of how I use all this—I sample a small amount of audio from the speaker output lines through a shielded cable and feed it over to the one R/T board I have built into my audio control unit in my console. The audio unit allows me to add tones, touch-tones™, and the like to my rigs, and also has decoding for the receive side of things. By adding the R/T board to the unit, I now can place any of these tones, voice from the station microphone, or audio from the receivers into the transmitter portion of the R/T board and ship it anywhere on my property

where 120 V ac, 60 Hz is run.

Out on the remote end, where you have taken the R/T unit, this audio is taken back off the power line, decoded if required, and/or amplified up to speaker level. It has been a ham shack-to-garage and tower-house intercom, a control unit from shack to tower house for EME array control (a 150-foot unwired blessing), and even a two-way setup back to the woods almost half a mile away—where all I run out there is a low voltage, 24-V ac line to avoid electrical code (and cost) problems. See Fig. 3(b).



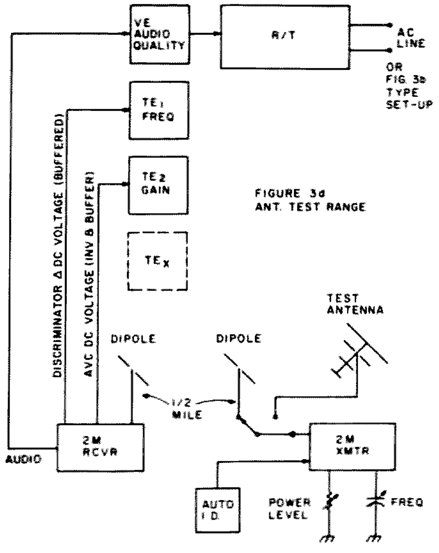


Fig. 3(d).

The two R/T units, in that case, are merely coupled into the 24-V ac secondary of the ham shack end and decoupled at the 24-V ac primary of the woods end. The woods-end transformer then transforms back up (to the 48 V ac I needed for a 30 V dc and allowing for line drop from the ham shack to the woods). Direct current control is sent down the same two wires for a one pair/three duties system.

My only concession in the R/T use was to utilize different rf frequencies each way, so that I can override receiver audio coming my way when I want to transmit either audio or a control tone. For monitoring the local repeater from anywhere in your house, it is great! A single tone is sent along with the microphone audio while you are transmitting. After the audio is demodulated from the rf carrier and leaves the R/T board at the ham shack end, it goes two ways. The audio goes through a parallel trap to reject the tone, to a one-stage audio amplifier (later found to be unnecessary), and, via a pot, to the microphone input circuit. The pot allows me not to have to change levels in the radio or station microphone setup.

The second audio direction is for the tone; it is through a series pass filter, to reject audio and pass tone, and back to the one-tone filter and decoder you see in Fig. 2. That, in turn, when sensed and decoded, pulls in a relay and keys the transmitter. In the other direction, the audio mentioned earlier, from a receiver-speaker circuit, is coupled into the transmitter half of the ham-shack-end R/T board and put on the ac power lines. Back where I am (remote), the receiver portion of my R/T board demodulates the audio from the rf carrier, amplifies the audio, and presents it to me at the speaker.

I have added some complications since I want to monitor more than one radio and I don't just want to listen to noise at the remote end. On FM, that is not bad, as the radio has a squelch that keeps the audio off the transmitter input line of the ham shack R/T board, but I also monitor 50.125 MHz on SSB. To get around this, I have an audio-type squelch in the audio console that, when the radio speaks, keys a tone along with the audio (sort of continuous-tone squelch style). When this tone gets to my unit (remote), it is handled just like the other direction, by splitting the audio and tone. The tone also lights an LED corresponding to what tone is controlled by which radio spoke. By using more than one tone at the remote end, I can control which radio I am putting the microphone audio into and keying. That about sums up one of my dandy uses, one of the reasons for writing this article, and the prime reason for my expanding it beyond just the PC board layouts.

I have changed some of the pin numbers of the ICs due to my board layout, so I have re-drawn the entire R/T board schematic as Fig. 4. The numbering on Fig. 4 and the layout now agree.

In the original article—in case they are not caught in the reader's column—let me say that there were a few errors and omissions. The pins on the "B" tone oscillator in Fig. 2 were omitted. I completely changed these, due to my layout, but in the original article, the left part should have inputs of 8 and 9 and an output of pin 10, and the right part, inputs of 12 and 13 and an output of 11. Left for right numbering can be traded, if it makes your wiring easier, but don't accidentally trade inputs for outputs.

The four parts of the IC are identical in operation. In the original Fig. 5, the ICs were labeled incorrectly as 576s. They are the familiar 567s. And while I am on the 567s, beware of too much tone input. 50 mV should be maximum, if you want to preserve any narrowband characteristics. Q5, in Fig. 4, can supply much more than that. I have added limiter diodes to the circuits and a level pot that you can adjust on the PC board. If you have tone-falsing and -failing problems, act accordingly.

One other comment on the original article. Fig. 6 shows how to re-wind the rf transformer. While this worked well, it was a lot of work. I allowed, on the PC layout, for you to use a much more common coil form put out by many vendors through most supply houses. Wind the transformer on it in exactly the same manner as shown in the original article, cover with a matching small i-f coil shield, and the results will be the same. I also left the coil pinout the same, so don't forget the jumper

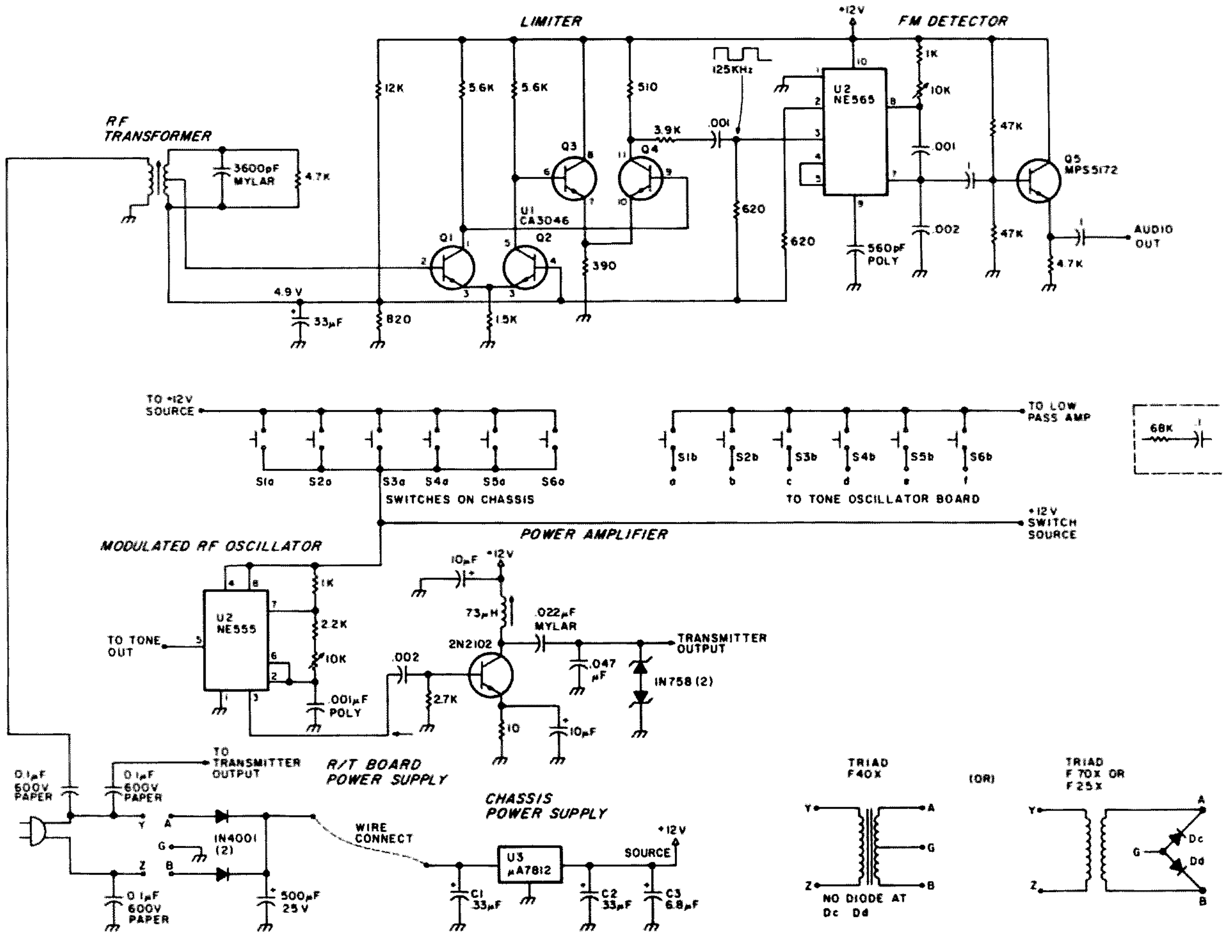

Fig. 4. Mount 7812 to chassis heat sink. Choose R2 and CX for desired tone. Recommended values are R2 = 100k pot and CX = .001 to .0047. Trim pot around center and change CX for coarse range.

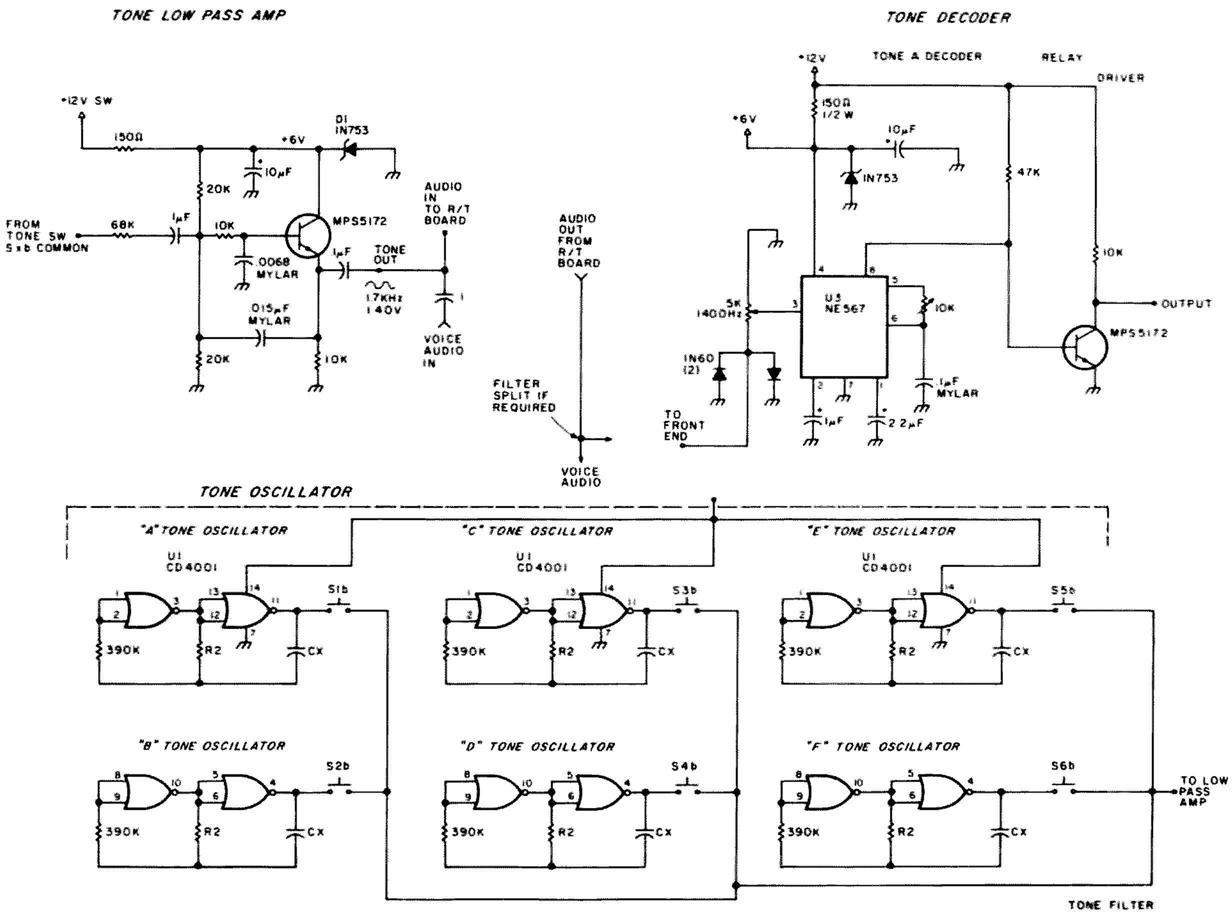
wires (five are required) from the transformer base to each circuit. If any of the jumpers have to cross, be sure they are insulated wire.

I'll add in here a few useful notes on Fig. 3 concerning the hookups and the parts to use. Fig. 3(a) shows the simple form of wireless intercom unit used as a transceiver extension or remote. The mA units should be whatever matching transformers the microphone and speaker require to properly couple to the R/T board. The ham shack mA units are handled the same way, properly matching your rig with respect to microphone input and audio output (phones or speaker). Since this will vary so widely, I have chosen only to block-diagram it. Keep it as simple as possible at first, until you see what you really must have. For example, use a .1 capacitor from the speaker line to the R/T unit and from the radio audio gain-control to control-level. Add a pot for level later, and/or come off ahead of the rig gain control, to allow a quiet rig in the house with the XYL while you monitor from out in the garage or wherever you might be. Then add the audio amplifiers where required. There are many cases where audio amplifiers might not be needed at all.

Fig. 3(b) is a special case. I have found it very useful to reduce wiring between two points when there is *not* already a 120-V ac, 60-Hz line. See Fig. 3(b). If you run a safe wire, like rotor cable with good insulation, not many codes would prohibit such an installation. If 120-V ac wiring were run, all kinds of codes, regulations, electricians, and costs get into the act!

Skipping over Fig. 3(c) for a few paragraphs, since it is really a part of Fig. 3(d), Fig. 3(d) concerns a special situation not covered in Fig. 3(b). It allows a simple, remote transmitter-receiver pair to be located remotely from the ham shack/antenna location. The remote site then forms the heart of my antenna test range. Provisions are made for voice to return back over the wired circuit for both checking audio quality and intercom use when someone is at the remote site. Next, one channel (rf) of the wired remote is wired to use the buffered dc voltage from the receiver's discriminator (the VHF receiver). The buffer also shifts the level to allow direct use with the 555-modulation pin (all positive voltages), by shifting the discriminator minus 6 — 0 — plus 6 V dc (approx.) over to a 9- to 11-V dc shift. When the receiver is right on, the 10 volts then represent 0 V at the discriminator. Since the transmitter end (VHF) is where you are, the frequency is used to be sure you are sending right in the center of the receiver's (VHF) passband, where the receiver has been aligned, calibrated, and measured. That is, uV antenna strength equals some arbitrary avc reading, recorded. You use your reference dipole—see Fig. 3(d)—to



TONE FILTER
TONE DECODER
TONE GENERATOR

the remote-site dipole first each time, and if the frequency reads all right, then any differences should be in the path (not likely at ½ mile, but weather affects it some) or in the receiver itself, due to some factor such as temperature or aging. Then you proceed with your test antenna, compared to previous antennas, and the reference dipole using the avc voltage reading on a separate rf-wired channel.

Using the separate wired channels of rf allows continuous monitoring of all, simultaneously. I intend actually to monitor three voltages (plus frequency) in this measurement, along with a low-power transmitter whose output I can both accurately measure and vary continuously from 1 to 10 Watts. The remote receiver can be any FM unit on the frequency of your antenna interest, but preferably solid state to reduce power consumption on your 24-V ac line out to the site. Then you measure and send back (by three rf channels) the two limiter and avc readings.

By varying the transmitter level, you can keep the receiver down out of limiting where the avc is linear or, at least, repeatable. Remember, you are not trying to recover audio from the VHF transmitter at the VHF site at this point, but only to compare the signal strength of two antennas: the reference dipole vs. your new model. The range is approximately ½ mile, or 2640 feet, or 417 wavelengths on two meters, and gets better as you go up in frequency. This keeps reflections and stray ground clutter to a minimum, as well as allowing you to plot your antenna, and any stray lobes, accurately. You require only a well-calibrated antenna rotor and readout. My remote site is due east (90 degrees) from me; that becomes 0 degrees on the antenna plot. The north rotor stop is a pain you live with, but I avoid extra work by starting at 270 degrees plot (due north—compass) and plotting around through straight at the site and through 360 degrees in 5-degree increments.

If you try this kind of work, always allow a full 360 degrees around—and then back in 5 degree increments. Trying two or three such trips and averaging the results is even better. This allows for any rotor over-travel or coast when stopping. Whatever you do when comparing antennas, or how you do it, never—repeat never—believe the reports of signal strength changes from antenna to antenna that you get from another station. Modulation, keying, etc., is all right, but unless you like to climb towers, changing antennas back and forth and never seeming to get anywhere, stick with a measured system. This is not to say you can never have another amateur whose setup and serious attitude matches your own or the level of confidence you want, but to suggest you don't buy the casual-type observer. He may have changed rigs, antennas, and use his deaf ear for an S-meter! Why do you think I went to the trouble of a range?

Fig. 3(c) was thrown in to show how I can control 16 channels of rf using only eight frequencies and up to as many audio tones as you

can discriminate between or use without ending up in a crossfire mess. If the numbers and the control pad look familiar—they should! I claim no credit for this idea, beyond acknowledging that a lot of work and research (translation: money!) went into the selection of the touchtone™ frequencies used by the phone companies. Such things as harmonic relationships and beats were all thought out for me; I just shifted the tones up to rf frequencies and used the same 567 decoder scheme used by many autopatch setups, but at rf frequencies. The 567 is good up to 500 kHz, so I am well within limits. Add to the fact that audio down a power line would compete with the 60 Hz and be hard to separate, and the 10% bandwidth at rf is several cycles you can easily zero in on versus a few cycles at audio, and you realize why the shift up and the manner I did it.

Fig. 4, as stated earlier, is just schematics—the same, almost, as the originals electronically, but divided up as they appear on the PC boards and numbered in the PC board manner for easy troubleshooting.

I'm sure you will find at least as many uses for this terrific circuit combination as I did, so I hope the PC boards make it a lot easier for you. Any other uses or ideas using these little gems I'd like to hear about, and an SASE is required only if you need a reply. Electronics or circuitry questions should go direct to N2CX, and PC board or uses questions to me, to keep things sorted out. Give remote control a try—you'll like it, I bet! ■

New Products

tunity to save time and money in QSLing as well as have an instant reference right at his fingertips. Duplicate QSLing will become a thing of the past. You know at a glance what you have worked, on what bands and modes, and, most important, what needs to be confirmed. Each call area of the United States is divided by state, band, and mode. An extra column is provided for new modes or notes. As an added feature, a section is provided for every country of the world. "Insta-Pac" is attractively packaged and would be an asset to any ham shack. It has been developed by KH6ITY and is offered with an unconditional money back guarantee if not completely satisfied.

For further information about this new system, contact *Insta-Pac, PO Box 22974, Honolulu HI 96822.* Reader Service number 143.

NEW BEARCAT® POCKET SCANNER RECEIVES BOTH AIRCRAFT AND GROUND-CONTROL COMMUNICATIONS

The world's first pocket-size scanner radio capable of receiving both the VHF-AM aircraft channels and UHF-FM channels has been introduced by Electra Company. For the first time, airport officials, operating personnel, pilots, and others interested in airport operations can carry in their pocket a single radio which can keep them informed of both tower-to-plane and ground-control communications. The new "Bearcat® Thin Scan Aircraft" scanner is just 2¾ inches wide and 1 inch thick, and weighs a mere 10 ounces, making it a true pocket portable. The radio is capable of receiving up to 4 channels in any mix of the two bands covered. Each channel is provided with a lockout control for bypassing when desired.

Blueprint for Biofeedback Experimentation

—fertile ground for pioneers

The idea for this article came from an experiment into the capabilities of human movement and control. The main question was how it would be possible for a person to control electrical devices and effectively communicate without movement of any kind. This restriction included the use of speech, sound, or any alteration of respiration.

Upon first consideration it seemed an impossible task, as the only apparent control would be over thought. This is where the idea of control by brainwave came to mind. No, I'm not talking about ESP or psychokinesis, but biofeedback. Biofeedback is the process of monitoring and controlling certain body functions . . . in this case, alpha brain waves.

The main purpose of biofeedback is to provide greater relaxation and creativity by controlling certain types of brain waves. In this article, we will be concerned with alpha waves.

A device called a "biofeedback monitor" is used to amplify and detect alpha waves in much the same way as an electroencephalograph. A band containing electrodes is fitted around the head, and when the brain is producing an abundance of alpha waves, the monitor gives indication with a tone or light. By learning to control the tone or light, you learn to control your alpha waves.

At this point, I'm sure you are beginning to see the *modus operandi* of the alpha control. Fig. 1 shows a simple block diagram demonstrating the basic principles involved. In this diagram, a photocell light and its counterpart, a tone-voice-operated microphone, are used to show a working system in its simplest form.

While the system described would work, it was not made to replace electronic switching and logic circuits, which would be more accurate. Schematics for an actual control circuit have been omitted, as the design and construction would vary greatly with the type of monitor ouput.

There are three major types of outputs used in the majority of monitors. They are: threshold tone, frequency-modulated tone, and light or LED indicator.

As for the monitor itself, you can get it pre-assembled or in kit form. There are models with simple one-mode outputs and ones with more complex multimode outputs. The range of control can be increased by the addition of a transmitter connected to the monitor and a receiver connected to the actual control circuit. A wireless microphone and receiver would work nicely, and possibly allow the utilization of existing equipment.

The next logical step would seem to be to develop a means of controlling more than one device. One possible but untested idea would be the use of a row of lights that would flash in sequence, somewhat like a public band scanner. By having the lights represent controlled devices, or letters, any number of appliances might be controlled simply by stopping the scan on the desired light and device it represents. Of course, the speed in which one could control his alpha waves would be a factor in the speed of the scan. In such a manner, a person totally paralyzed could communicate and, to some extent, control his environment.

It has been my honest effort to present these ideas in more than the light of a laboratory or scientific curiosity, and I now leave further experimentation and development to your able ingenuity. ■

The History of Ham Radio

—part X

Reprinted from QCC News, a publication of the Chicago Area Chapter of the QCWA.

The Second Radio Telephone Conference, called by Secretary Hoover, convened on March 20, 1923, to solve the deplorable situation brought about by the controversy over wavelength assignments. Broadcasters, the amateurs, the Army and Navy, the ship operators, and the commercial interests could not come to a common agreement as to wavelength allocations and thereby avoid woeful interference. Clearly, from an administrative standpoint alone, the broadcast listeners were desperate. The impasse which existed required a solution.

After several months of meetings, serious discussions, and lengthy deliberations, not even the amateurs had guidance or a clear go-ahead on how to interpret their standing with the Commerce Department. The American Radio Relay League had made a series of suggestions. The amateurs in all parts of the country, now almost 21,000 in number and licensed to operate in the narrow 200-meter range, found solace in the fact that they had pooled their ideas and suggestions through their respective district directors.

The ARRL Board of Directors based high hopes on all of these inputs. So, when recommendations were issued on June 28, 1923, by the Department of Commerce in the form of General Letter #252, directed to all government district radio inspectors, they read as follows:

C.W. Licenses

DO you fellows know that your station license provides that the apparatus described in the application shall not be changed without permission? And that a license granted a spark station is not good for the use of C.W. equipment? It sounds queer, considering that any complaintant ought to prefer a tube set to a spark, but if anybody wants to "get" you on it they can.

A broadcast listener recently filed a complaint with a radio inspector against a well known eastern spark amateur, alleging the use of an illegally broad and too-long wave. Called upon the carpet, there was no evidence that his spark, which was good as such animals go, was not entirely legal. But he volunteered the information that he was experimenting with C.W. anyway and the interference probably would be still further reduced. Whereupon, altho his spark set was O.K., he was informed that the use of C.W. was in violation of his license, and it was suspended for three months.

Moral: If the equipment you are using is greatly different from that for which your license was issued, take up the matter with your Inspector and "get right."

QST - March, 1923

General Letter #252

"General and Restricted Amateur Radio Station Licenses will be issued permitting the use of any type of transmitter (CW, spark, ACCW, ICW, SC, and phone) with the restriction that when using pure CW, they are authorized to use wavelengths from 150 to 200 meters. When using spark, ACCW, ICW, unfiltered SC, and phone, the wavelengths from 175 to 200 meters only can be used. The types of transmitters must be specified in the application and the license.

"Special Amateur Radio Station Licenses will be issued permitting the use of pure continuous wave transmitters only, authorizing the use of wavelengths from 150 to 220 meters.

"For the purpose of application of Amateur Stations, pure CW is defined as follows: A system of telegraphing by continuous oscillations in which the power supply is substantially direct current as obtained

from (1) a generator, (2) a battery, or (3) a rectifier with an adequate filter. (A filter is not deemed adequate if the supply modulation exceeds five percent.)

"On licenses issued for Amateur Stations you will include the following: 'This station is not licensed to transmit between the hours of 8:00 and 10:30 p.m., local standard time, nor Sunday morning during local church service.'

"Special Amateur Stations must be operated by persons holding an extra first class grade Amateur operator's license, or a commercial extra first class operator's license. Applicants must also meet the requirements of Regulation 63.

"A new class of Amateur operator's license is hereby established, to be known as 'Amateur Extra First Grade.' Licenses of this grade will be issued to persons passing the required special examination with a percentage of at least seventy-five and code speed in sending and receiving at least twenty words per minute, five characters to the word; who have had at least two years experience as a licensed radio operator; and have not been penalized for violation of the radio laws subsequent to the date of these regulations."

The government supervisors, located in the several United States radio districts, upon receiving the new regulations, were requested to notify all amateur radio licensees, general and restricted, to submit their respective license papers to the supervisor's office and have them modified in accordance with the new regulations. After they were so certified with a copy of the new rules appended, they were returned, officially endorsed, extending the wavelengths range and specifying the quiet hours. No changes were made in their expiration date.

All amateurs who held *special* licenses were notified that their licenses were cancelled and new licenses would be issued in accordance with the new permits now granted. Up to the present, all amateur licenses were issued specifying the wavelength of the operating transmitter to be used. From this date on, a license permitted a station to change the operative wavelength to accord with the bandwidth permitted and as the type of emission specified.

Variable frequency transmitter circuits were not generally known among amateurs. The progress of the art and the know-how was still lacking in 1923 in this respect. Even the well-informed and up-to-date amateur solved the changing frequency problem by having more than one transmitter available, usually a pure CW of low power and another with either ICW or ACCW plate supply. Every license issued by the Commerce Department required that the licenses specify not only the wavelength limits of the transmitter, but also the emission type and the apparatus to be used including the antenna length and construction. If an amateur qualified as an extra grade operator, he could apply for two licenses, a special and a general. The special was then given a "Z" call.

The ARRL had recommended that the amateur with two years of experience and a twenty-words-per-minute code speed be issued an extra first grade amateur operator's license using a wave transmission length up to 220 meters. (Even at this date all authorities assumed that this stipulation was a decided advantage for DX.)

It also was understood that transmissions on wavelengths other than 200 meters by the amateurs could be allowed on the issuance of a license specifically noted on the application. A second wavelength, perhaps somewhere between 175 to 180 meters, could be granted. The 150 to 220 meter band specified in the 1923 Regulations gave the Secretary authorization to grant licenses upon request provided the amateur could meet the stipulated requirements and so requested in his application.

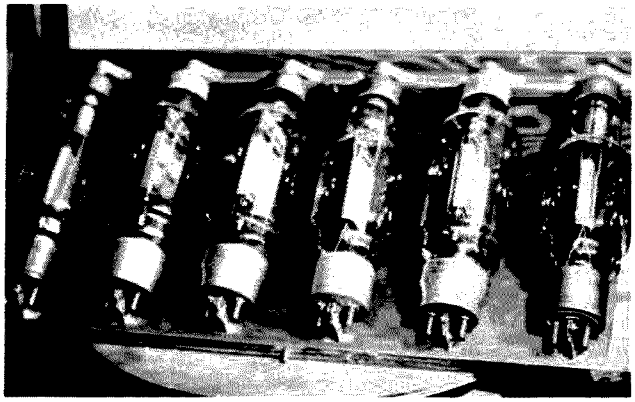

Fig. 1. The 250-Watt UV204.

How the Need for "Plate" Power Was Met

In the early wireless days, the conversion from simple spark coil to high voltage rotary-gap transmission was not difficult. But going over to the vacuum tube for CW operation was by no means an overnight accomplishment. To put continuous wave power into the antenna, the amateur initially had available a small amplifier tube and a larger five-Watter, known as the UV202. Subsequently the fifty-Watt 203 was available, followed soon by the 250-Watt UV204, a real "power-house" for most DXers (Fig. 1).

With the introduction and development of the power tubes, there naturally was need for a direct current supply to energize the plate circuit. Much of the spark gear the amateur had accumulated and used for a power source was now destined for the surplus stockpile. The new regulations specified pure CW or nearly so, and this necessitated some type of direct current source, often up to several thousand volts. Various methods to obtain this voltage were outlined in the ham literature: (1) a motor generator, or (2) a battery, or (3) a type of rectifier with filter. Much experimenting took place. This voltage was referred to as the "B" voltage supply.

The Motor Generator

Although not the most practical source of high voltage dc nor the least expensive, a generator was the easiest and simplest way to quickly come up with plate power of one- to two-thousand volts. The ESCO machine from Electric Supply Co., of Stanford CT, could be found in many ham shacks. Early commercial broadcasters also used this equipment. However, the supply required filtering to reduce the ripple modulation to a point where it would meet the specified five percent. Using a motor generator required ac starting controls, considerable power wiring, and usually a remote and out-of-the-way installation of the entire unit to reduce hum and noise when operating voice modulation. Weight and expense were

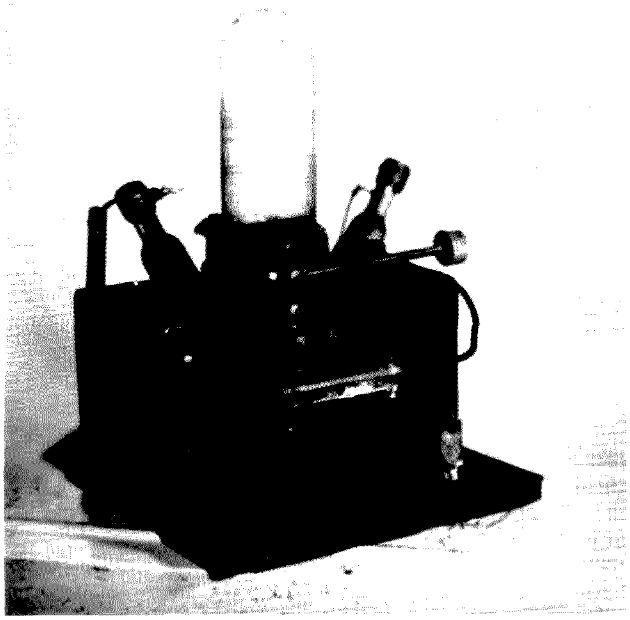

Fig. 2. A one-kilowatt transmitter.

responsible for the few installations of this kind.

Edison and Lead-Acid Batteries

Edison-type batteries were available built in small but compact units. They were kept charged with a Tungar charger-rectifier connected to house current. The lead cells could be obtained in compact assemblies giving sufficient wattage for the smaller transmitting tubes. All these units were messy and, besides giving off a gas odor, ruined many floors and carpets.

Typical of what certain amateurs were capable of and determined to build is illustrated by the enviable installation of radio NU9BHT. This beautiful layout required assembling and building one thousand individual lead-acid cells. They were contained in 4½″×5½″ hard rubber cases, with one positive and two negative plates per cell. Hard rubber trays contained 25 cells each and were treated with acid-resistant paint to provide protection and longevity. With each bank delivering 50 volts, separate switches were used to make appropriate connections for charging each bank, either separately or in four bank series of 200 volts. A motor generator battery charger delivering 250 volts kept the batteries fully charged.

Installations of this type necessitated adequate ventilation, care, considerable service, and a separate building to house the equipment. The circuit diagram of the station transmitter adapted itself to frequent modifications and changes to keep it up-to-date.

With the development of crystal control and other experimental features added from time to time, NU9BHT established an enviable record while in service. Operating primarily on 40 meters CW and occasionally on 20, as an official ARRL relay station, it contacted all Australian districts, making five-continent QSOs in one evening. This was an exceptional accomplishment back in 1923. Not many installations of this type prevailed in hamdom. With a battery voltage source, no filtering was required. This was *pure* dc!

The Rectifiers, Mostly Chemical

Over the next few years, the various amateur publications carried a series of suggestions for methods of building rectifying equipment for the B supply.

How did the amateur go about putting together a chemical rectifier? He was on the lookout for—item one: chemically pure aluminum sheets; item two: chemically pure sheet lead; item three: a quantity of pint-sized jars; item four: several pounds of borax; item five: plenty of distilled water.

For each cell assembly he figured that approximately 40 volts could be rectified from a 60 cycle source. This translated to about 50 cells required for a 2000-volt output. Forming and placing such a home-built rectifier initially into operation required a great deal of experimenting to overcome a whole series of mishaps. Rectified ac output of this type was always accompanied by a 60-cycle ripple hum, which

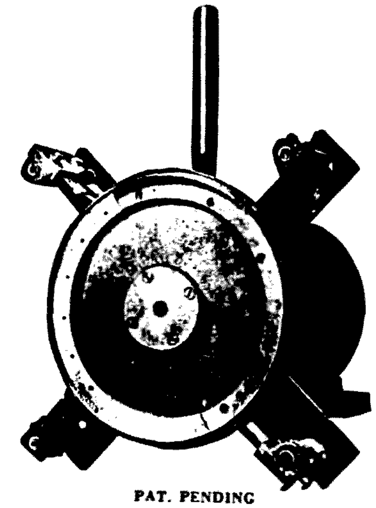
THE SUPER-SYNC

The synchronous rectifier that can be filtered

The Super-Sync is the only rectifier that delivers a pure D.C. tone and gives 100% rectification at all times.

It is the only rectifier that is adaptable to either high or low power sets as it easily handles up to 4,000 V. at 250 M.A.

The commutator on the Super is eight inches in diameter and is driven by a ¼ H.P. 110 V. 60 cycle 1800 R P M synchronous motor.



PAT. PENDING
PRICE $75.00 F. O. B.

With the Super there are no materials to change—just connect the motor and high voltage leads and forget about it as the only attention required is an occasional oiling of the bearing.

The Super practically eliminates interference caused by other types of synchronous rectifiers.

Write for descriptive literature.

MARLO ELECTRIC CO., 5241 Botanical Ave., St. Louis, Mo.

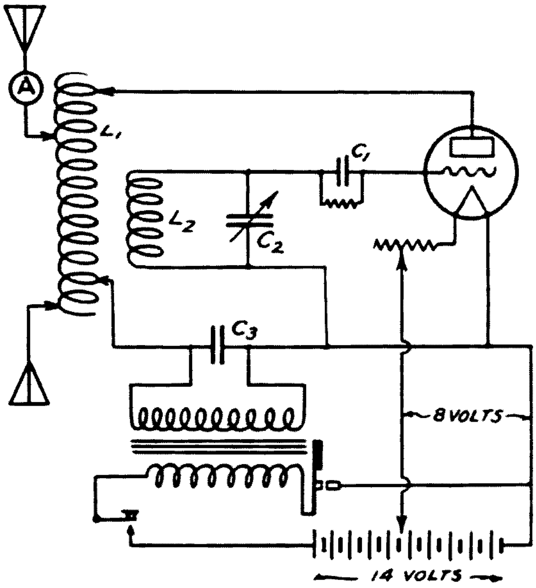
Just an Efficient and Reliable Form of Rectification

Fig. 3. A synchronous rectifier.

With a half inch spark coil a hard receiving tube may be used; either the Cunningham C.301 or the Radiocorp U.V.201 is suitable. For larger coils the 5-watt C.302 or U.V.202 may be used but less filament power is consumed by the Western Electric "E" or VT-1 tube. No 50-watt tube with proper plate insulation for spark-tube work is available just now but the C.303 or U.V.203 can be made to do.

Various circuits have been described in our pages in a paper called "A Spark Coil C.W. set," by Samuel Kopelson of 2BCF (May 1922—p. 66), and in "A Spark Coil C.W. Transmitter," by F. J. L. Duffy (March 1922—p. 28). In *The Modulator* for January 1923 there appeared on page 17 a concise paper by M. Joffe describing his spark-tube set at 2BYO.

The best plan of all is to remove the secondary entirely and re-wind the coil with wire 6 or 8 sizes larger. Robert Kraus of 2CEI finds that for a Ford spark coil the best secondary is one having 5000 turns of number 32 A.W.G. (B&S) double-cotton-covered wire. When the secondary is re-wound in this fashion no shunt condenser is needed in Fig. 4 and even for the other circuits it can be reduced to .001 microfarad. Three sheets of 4 x 5 tinfoil between 5 x 7-inch glass sheets 1/8 inch thick is more than enough.



L1—25 turns bare No. 10 wire on a 5-½ inch tube.
L2—20 turns No. 18 S.C.C. copper wire on a 3 inch tube.
